PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain two-hundred abstracts and twenty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume IX covers the scientific literature published from July 1970 through June 1971. A cumulative subject and author index for Volume IX will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows:

- 0001 MALIGNANCY FROM RADIUM. (E.) Loutit, J. F. (Med. Res. Counc., Harwell, Didcot, Berkshire, England). *Brit J Cancer* 24(2):195-207, 1970.

A review of the literature of the carcinogenic efficacy of occupationally or therapeutically acquired radium indicates that osteosarcoma has been regarded as the chief limiting hazard of internally retained radium. Other malignancies associated with radium exposure are carcinoma of the mucosa in the cranial air passages, bone marrow dyscrasia and a "regenerative euopenic anemia" with features of atypical leukemia. Three cases of radium poisoning from England showed features compatible with aleukemic leukemia and malignant myelosclerosis, a finding which supports the thesis that malignant transformation in the lymphomyeloid complex should be added to the accepted malignancies of bone and cranial sinus epithelium as limiting hazards from retention of radium. (31 references)

- 0002 VARIABILITY, STRUCTURAL GLYCOPROTEINS AND CLASSIFICATION OF HERPES SIMPLEX VIRUSES. (E.) Roizman, B. (Dept. Microbiol., U. Chicago, Ill.), M. Keller, P. G. Spear, M. Terni, A. Nahamias and J. Dowdle. *Nature* 227(5264):1253-1254, 1970.

Although herpes simplex virus, which has been implicated in cancer of the cervix and lip, is usually divided into 2 types, those isolated from lesions on body parts other than the genitals and those isolated from genital lesions, these viruses do not fall naturally into 2 classes, but form a continuously varying spectrum. Type 2 variants of herpes simplex virus strains have given rise to type 1 strains, and virus strains intermediate between the two types have been described. The MP strain of the virus appears in neutralization tests to be intermediate between 2 prototypical strains from each of the 2 divisions. Furthermore, herpes simplex virus is very variable in the laboratory, giving rise to a wide spectrum of mutant strains. The basis of the high variability of the surface of the virus might be the nature of the envelope of the virus, which may be affected by glycosylating enzymes in the host from which the viruses are derived. In spite of their clinical and behavioral differences, and the differences in the buoyant densities of their DNAs, the genetic differences between type 1 and type 2 herpes simplex virus are minor and are breached by multiple mutations in the laboratory. (29 references)

- 0003 CANCER VIRUSES IN PRIMATES. (E.) Kinard, R. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Science* 169(3948):828-831, 1970.

Four projects in the Special Virus Cancer Program are described in which breeding colonies of primates are developed for the purpose of providing newborns to be inoculated with a variety of known viruses or malignant cells presumed to contain viruses. Newborn primates at the Bioentics Research Laboratories, Kensington, Maryland are inoculated with the following agents: adenovirus 12, simian virus 40, echovirus 9, reovirus 1, reovirus from Burkitt's lymphoma, Rous sarcoma vi-

rus, Moloney sarcoma virus, rubella virus, herpes genitalis virus, herpes-type particles in chimpanzee leukocyte culture; tissues and cells from patients with myelogenous leukemia (acute and chronic), lymphocytic leukemia (acute and chronic), Hodgkin's disease, Burkitt's lymphoma, polycythemia, rhabdomyosarcoma, epidermoid carcinoma, warts, infectious mononucleosis, and myelogenous leukemia. Inocula studied at the Baylor College of Medicine, Houston, Texas, include: fresh plasma or bone marrow cells from children with acute leukemia, human wart suspension; lymphoblastoid cell cultures from patients with leukemia, Burkitt's lymphoma, or infectious mononucleosis; adenoviruses 2, 7, and 12; reoviruses 1 and 3; echovirus 9; simian adenovirus 7, 3 strains of rubella virus; cytomegalovirus; and herpes simplex virus. In this project, the following carcinogens are also studied: X-irradiation, Imuran, prednisone, urethan, benzpyrene. At Presbyterian-St. Luke's Hospital in Chicago, inocula of the following origins are used: Bryan strain Rous sarcoma virus, DiGuglielmo's syndrome (erythroleukemia), human papilloma, Burkitt lymphoma (Epstein-Barr virus), Kaposi sarcoma, and cat leukemia. This project has succeeded in inducing fatal metastasizing sarcomas in marmosets by inoculation with the Schmidt-Ruppin strain of Rous sarcoma virus. The fourth project, at the Institute for Comparative Biology of the Zoological Society of San Diego, California, is concerned with evaluation of the reproductive potential in captivity of several species of small primates. (13 references)

- 0004 EPSTEIN-BARR VIRUS, INFECTIOUS MONONUCLEOSIS AND BURKITT'S LYMPHOMA. (Ger.) Waubke, R. (Med. Clin. Polyclin. U. Giessen, Germany). *Deutsch Med Wschr* 95(30):1572-1578, 1970.

Experimental investigations with Epstein-Barr virus (EBV) and its relation to infectious mononucleosis, Burkitt's lymphoma and other malignant tumors are reviewed. EBV induces a latent or not yet clinically correlated viral infection in man usually during childhood. The incidence of this infection is about 2000 times higher than that of infectious mononucleosis. EBV may induce infectious mononucleosis in adults lacking EBV-antibodies, subsequent organ infiltration and leukemia may occur. Infectious mononucleosis is possibly an immune response to an oncogenic viral infection. (69 references)

- 0005 BURKITT LYMPHOMA AND MALARIA. (E.) Anonymous. *Lancet* 2(7667):300-301, 1970.

The epidemiological evidence incriminating malaria as a contributory factor in the etiology of Burkitt lymphoma is reviewed. Burkitt lymphoma is concentrated in the 2 areas of the world (tropical Africa and New Guinea) where malaria is holoendemic; anomalies in the distribution of Burkitt lymphoma may be linked with local control of malaria. Epstein-Barr virus has been identified in Burkitt tumor cells, but the nature of the interaction between virus, malarial parasite, and lymphoid tissues remains obscure. The simplest view is that lymphoid tissues which are subjected to persistent stimuli and stress by the parasites are somehow rendered more suscep-

tible to neoplastic transformation in the presence of Epstein-Barr virus. The reticuloendothelial system is probably involved, but evidence of anti-malarial immunity and of enhanced non-specific activity in this system is not forthcoming. Incompatible with the theory of the essential involvement of the reticuloendothelial system is the fact that patients with Burkitt lymphoma have normal or low levels of serum-immunoglobulins, usually accurate indices of immunological stress and response. (19 references)

- 0006 BURKITT'S LYMPHOMA AND MALARIA. (E.)
Burkitt, D. P. (Med. Res. Council External Staff, London, England) and G. W. Kafuko. *Int J Cancer* 6(1):1-9, 1970.

The evidence for a relationship between Burkitt's lymphoma and malaria is reviewed. Burkitt's lymphoma is known to be endemic only in areas where malaria is still holoendemic or hyperendemic. Areas where intensive malaria eradication campaigns have been undertaken are nearly tumor free, and in areas where malaria control has been instituted only recently, a marked fall in incidence of Burkitt's lymphoma has been observed. The peak age-incidence of Burkitt's tumors corresponds to the period of highest malarial infestation. A lower incidence of sickle cell anemia and AS type hemoglobin which confers a relative immunity to malaria, is seen in patients suffering from Burkitt's lymphoma. Mice infected with chronic malaria and subsequently developing an immunity, showed an increased susceptibility to this tumor. The evidence suggests a causal relationship between malaria and Burkitt's lymphoma. (28 references)

- 0007 GLUCOSE METABOLISM IN TUMORS AND VARIOUS THEORIES ON CANCER BIOCHEMISTRY. (Ger.)
Gorlich, M. (Robert Rossle Clin., German Acad. Sci., Berlin). *Arch Geschwulstforsch* 35(3):261-277, 1970.

The role of glucose metabolism in tumors as related to carcinogenesis and specific tumor cell metabolism is reviewed. Warburg's hypothesis on aerobic glycolysis as a specific feature of tumor tissue metabolism and growth, Greenstein's convergency hypothesis (enzyme functions and gradual dedifferentiation), Miller & Miller's deletion hypothesis (azo dye carcinogenesis), Potter's catabolic deletion theory (enzyme protein breakdown), the feedback deletion theory (alterations in the regulation of transfer of genetic information), extra- and intracellular regulation defects of tumors and Hecker's information theory on cancerization (the initiation stage), are analyzed. It is concluded that the alterations in glucose metabolism should be considered as secondary events and not a primary cause in tumorigenesis. (84 references)

- 0008 CONTROL OF LYMPHOCYTE LEVEL IN THE BLOOD. (E.) Vincent, P. C. (Sydney Hosp., New South Wales, Australia) and F. W. Gunz. *Lancet* 2 (7668):342-344, 1970.

A model for control of lymphocyte proliferation involving a feedback mechanism is proposed. Detection of a recognition site on the surface of lymphocytes by the lymph node endothelium is suggested as a mechanism responsible for inhibition of proliferation. This recognition site could be identical or closely associated with the site(s) which react with phytohemagglutinin and other specific antigens to which the cell is committed. Cells in which the recognition site is either absent or blocked would not be detected by the lymph node endothelium, and proliferation would not be inhibited. The fundamental defect in chronic lymphocytic leukemia may be the loss of such a recognition site from the cell surface. (23 references)

- 0009 LYMPHOID STIMULATION AND LYMPHOID NEOPLASIA (E.) Anonymous. *Lancet* 2(7673):596-598, 1970.

The possible links between aberrant immune reactions and malignant lymphoma and leukemias are considered with particular reference to autoimmune processes. Hemolytic anemia, idiopathic thrombocytopenic purpura, Hashimoto's disease, rheumatoid arthritis, systemic lupus erythematosus and the Sjögren-Mikulicz syndrome are autoimmune conditions formerly thought to be exclusively symptomatic of the underlying malignancy, but now thought to be forerunners of the neoplastic process and perhaps intimately related to it. Continuous stimulation by self-antigen may evoke a sustained proliferative expansion of the forbidden clone of lymphoid cells, leading to neoplasia. Applicable examples of animal models are cited. (24 references)

- 0010 PHILADELPHIA CHROMOSOME IN LEUKEMIA. (E.) Anonymous. *Brit Med J* 3(5720):419, 1970.

The Philadelphia chromosome, which is accepted as a diagnostic sign of chronic myeloid leukemia, may not always be present in chronic myeloid leukemia, and it is occasionally found in patients presenting as cases of polycythemia. Because of the difference in treatments, the possibility of eosinophilic leukemia, a variant of chronic myeloid leukemia, should be considered in polycythemic patients who have a high white cell count at the time of presentation. Although there is evidence that hemopoietic cells other than those of the granulocyte series, specifically erythroblasts and megakaryocytes, show the Philadelphia chromosome condition, it is still thought that the Philadelphia chromosome abnormality is primarily associated with chronic myeloid leukemia not as its primary cause but as a secondary effect. (10 references)

- 0011 MEDICAL SYNDROMES ASSOCIATED WITH MALIGNANT TUMORS. (E.) Schottenfeld, D. (Mem. Sloan Kettering Cancer Ctr., New York, N. Y.). *CA* 20(1):35-43, 1970.

Twenty-two symptom complexes and metabolic aberrations which may be associated with cancer are listed, including dermatomyositis (associated with

lung, breast, and stomach cancer, and lymphoma); disseminated lupus erythematosus (associated with Hodgkin's disease and chronic lymphocytic leukemia); acute arthritic symptoms (associated with acute lymphatic leukemia in children); parenchymatous cerebellar degeneration (associated with lung and breast cancers); hypoglycemia and extra-pancreatic tumors (associated with fibrosarcoma and other mesodermal tumors); and polycythemia (associated with hepatoma and uterine fibroma). Tumors may be associated with disease of the connective tissue, neuromyopathies, and multifocal leukoencephalopathy by means of altered immune or auto-immune responses to organ-specific antigens which are elaborated by the malignancy. There is evidence that a tumor arising from non-endocrine tissue may synthesize peptides and proteins with hormonal activity, causing paradoxical hormonal effects. These effects may arise from the derepression or activation of latent coding functions in the DNA of tumor cells. (68 references)

- 0012 NONGONADAL NEOPLASIA IN TURNER'S SYNDROME. (E.) Wiertelcki, W. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), J. F. Fraumeni, Jr. and J. J. Mulvihill. *Cancer* 26(2):485-588, 1970.

The possibility that nongonadal neoplasia are associated with Turner's syndrome was investigated in a multihospital survey involving 289 patients. Of these patients 8 had nongonadal neoplasms (ganglioneuroma, carcinoid tumor, granular-cell myoblastoma, gastrointestinal carcinoma, leukemia, carcinoma of the thyroid); 1 patient had a hilus cell adenoma. A series of 20 patients with "male Turner's syndrome" revealed 2 patients with neurogenic tumors (pheochromocytoma and ganglioneuroma). The tendency to develop neurogenic tumors may be shared by syndromes with a Turner phenotype irrespective of a visible chromosomal defect. (29 references)

- 0013 CANCER OF THE EPIPHARYNX: REPORT ON 18 PATIENTS. (E.) Gudnason, D. (Reykjavik, Iceland). *J Laryng* 84(8):795-807, 1970.

A review of the literature on cancer of the epipharynx, which is accompanied by a report of 18 cases, indicates that the frequency of the condition is variable, being low in the white races, but high among the Chinese. Epipharyngeal cancer is more common in men than in women, but is not age-specific; cancers of the epipharynx are prone to metastasize to the lymph glands of the neck. Pathologically, cancer of the epipharynx usually appears as anaplastic squamous epithelial carcinoma or reticular cell sarcoma. Epipharyngeal cancers often present symptoms which mask the true complaint, and diagnosis is often delayed until metastasis has occurred. Most of the patients in the survey of 18 cases presented symptoms of the ear, nose, or cervical lymph nodes (following metastasis). The treatment of choice for epipharyngeal cancer is radiation therapy, although it is usually initiated too late to curb metastasis and early invasive growth, and tumors often recur after radiation treatment has ended. The

5 yr survival rate for epipharyngeal cancer is about 30%. (13 references)

- 0014 CARCINOMA OF THE BREAST: II. THE OTHER BREAST. (E.) Machleder, H. (Stanford U. Sch. Med., San Jose, Calif.). *California Med* 113(3):55-58, 1970.

A patient who has had a radical mastectomy for carcinoma of the breast still has 1 breast which is a target organ for carcinoma. Whether this patient should be subjected to any further treatment or vigilance than the patients in the general population depends on whether or not the chance that carcinoma will develop in this new target organ is more or less or is the same as for her statistical twin who has not had a mammary carcinoma. The indicated probability of developing carcinoma of the breast remaining after mastectomy varies in all studies, but much of this variation may be due to differences in the sample populations examined. A developing carcinoma in a mastectomized patient is more easily detected than in a previously unaffected patient, for the reason that the former patients constitute a more accessible population than the latter. The protective value of preventive simple mastectomy of the remaining breast is unproven, and it is not clear whether the carcinogenic stimulus is more apt to provoke neoplastic change in a remaining breast or in a small nest of residual axillary cells after simple mastectomy. (17 references)

- 0015 LUNG CANCER IN HEMATITE MINERS. (E.) Anonymous. *Lancet* 2(7676):758-759, 1970.

Three possible explanations are advanced for the increased rate of lung cancer observed in hematite miners in Cumberland, England, where it is estimated that hematite miners undergo a risk of contracting lung cancer 70% in excess of the normal population. High levels of radon which have been measured in the iron mines may account for the increased incidence of lung cancer in this population. It is also suggested that iron ore, with its 10% silica content, may be carcinogenic. Although asbestos, a complex silica containing iron, causes mesotheliomas, no mesotheliomas have been observed in iron miners. It is also possible that chemotherapeutic treatment for silicotuberculosis, which was a common cause of death prior to 1950, has left scarred lungs with encysted abscesses which develop into cancer; miners who now survive silicotuberculosis may live on to get cancer. (9 references)

- 0016 AIR POLLUTION AND HUMAN HEALTH. (E.) Lave, L. B. (Grad. Sch. Indust. Admin., Carnegie-Mellon U., Pittsburgh, Pa.), *Science* 169(3947):723-733, 1970.

A detailed review of the literature investigating correlations between air pollution and morbidity or mortality indices is presented. Data on the correlation of pollution and death from lung cancer from England are ambiguous, with some studies indi-

cating that there is a high correlation, and others indicating that correlation is insignificant. Data from the United States support a clear relationship between lung cancer mortality and air pollution, with city-dwelling nonsmokers having death rates between 43 and 120% higher than rural nonsmokers in various studies. Death from stomach cancer is also significantly related to air pollution, as are mortality rates for cancer of the esophagus and bladder. (115 references)

- 0017 SMOKING AND HEALTH. (E.) Fletcher, C. M.
(Roy. Postgrad. Med. Sch., London, England)
and D. Horn. *WHO Chron* 24(8):345-370, 1970.

A survey of the evidence linking smoking and mortality and morbidity from cancer, bronchitis and emphysema, peptic ulcers, heart disease, and tuberculosis indicate that cigarette smokers have an approximately 30-80% greater mortality than nonsmokers, a mortality which peaks in the 45-54 yr age range. More than 30 retrospective and 7 prospective studies have shown that the risk of lung cancer increases directly in relation to number of cigarettes smoked (for heavy smokers the risk is 15-30 times that for nonsmokers). The risk of lung cancer mortality increases with inhalation of smoke, early onset of smoking, taking more puffs on each cigarette, keeping the cigarette in the mouth between puffs, and with relighting half-smoked cigarettes. Mortality rates from lung cancer are lower for women smokers than for men smokers, for smokers of filter cigarettes than for smokers of non-filter cigarettes, and for pipe and cigar smokers than cigarette smokers: and mortality risk declines in those who stop smoking. Environmental factors associated with high lung cancer mortality rates include exposure to urban air components such as coal smoke, occupational exposure to asbestos dust, chromates, nickel, arsenic, radioactive materials, mustard gas, and the products of coal distillation in the gas industry. In all these areas, the risk of lung cancer is largely confined to smokers. Experimental studies have induced cancer in the skin of animals by application of tobacco smoke concentrates; squamous bronchial carcinomas have developed in dogs who had smoked 7 cigarettes per day for 29 months. The carcinogenic agents in tobacco smoke have not been identified, but benzo(a)pyrene is one known cancer initiator which occurs in high concentrations in tobacco smoke. (114 references)

- 0022 CHANGES IN TESTICULAR DNA PRODUCED IN BALB/c MICE BY DIETHYLSTILBESTROL. (E.) Uchikawa, T. (Natl. Inst. Radiol. Sci., Anagawa, Chiba-shi, Japan), R. A. Huseby, M. Zain-ul-Abidin and L. T. Samuels. *J Nat Cancer Inst* 45(3):525-533, 1970.

Large doses of diethylstilbestrol (10% content in an 8-10 mg pellet implanted subcutaneously) were administered to male BALB/c mice to investigate an hypothesized direct correlation between estrogens and tumors in the Leydig cells. The DNA content of the cryptorchid testes of treated mice was observed to increase with testicular weight gain, but DNA per unit mass also increased significantly. An increase in DNA secondary to similar treatment with diethylstilbestrol was not seen in (C3H/Bi X A/Bi)F₁ (ZAF₁) mice that have a significantly lower incidence of diethylstilbestrol-induced Leydig-cell tumors or in Holtzman rats in which estrogen-induced interstitial cell tumors have not been reported. Measurements of ³H-thymidine incorporation in the testes of BALB/c mice indicated an early (1-7 days) surge in DNA synthesis that was not detectable in ZAF₁ mice; autoradiographic studies of BALB/c testes demonstrated that this augmented incorporation was primarily, if not entirely, in the interstitial cells. Both quantitative and autoradiographic studies showed that ³H-thymidine incorporation then dropped to levels approaching those of untreated animals until the time of tumor development. Thereafter incorporation increased with the development of pretumorous nodules of interstitial cells, in which DNA synthesis was actively proceeding.

- 0023 CARCINOGENIC PROPERTIES OF ORTHOTOLIDINE (3-3'-DIMETHYLBENZIDINE). (E.) Pliss, G. B. (N. N. Petrov Res. Inst. Oncol., Leningrad, USSR) and M. Zabezhinsky. *J Nat Cancer Inst* 45(2):283-295, 1970.

o-Tolidine (20 mg once a wk) was administered by s.c. implantation or as an oil suspension for 13-14 months to rats in order to test carcinogenic properties. Tumor incidence was 60% in rats given the oil suspension, 64% in rats given the pellets and 78% in rats given pellets which had been subjected to ultraviolet irradiation. Tumors developed mainly in the skin and its related structures, the large sebaceous glands and mammary glands. Biochemical studies showed that subcutaneously administered *o*-tolidine accumulated chiefly in Zymbal's gland, which probably explains the induction of tumors in this organ. Subcutaneous implantation of pellets of *o*-tolidine caused subcutaneous sarcomas in 2 of 68 rats and hepatocellular carcinomas in 4; this effect was not observed when *o*-tolidine was administered as an oil suspension. *o*-Tolidine appears to be a carcinogen with resorptive action, indicating that the carcinogenic effect of this compound may be due to one of its metabolites.

- 0024 INVASIVE TUMORS INDUCED IN RATS WITH ACTINOMYCIN D. (E.) Svoboda, D. (U. Kansas Med Ctr., Kansas City), J. Reddy and C. Harris. *Cancer Res* 30(8):2271-2279, 1970.

Male rats received multiple i.p. or i.v. injections of actinomycin (0.025-0.050 mg/kg) or actinocylgrami-

cidin (0.5 mg/kg) and the resultant invasive tumors were subjected to histological and microscopic examination; the former compound induced invasive transplantable tumors, while the latter did not. The actinomycin-induced tumors appeared as multiple, gray or yellow, firm, irregular, pedunculated, or sessile nodules 2 to 10 mm in diameter attached to peritoneum, mesentery, and serosal surfaces of the abdominal viscera. Invasion into the muscularis of the bowel and, occasionally, infiltration between pancreatic lobules as well as into portal tracts of the liver was also observed. Microscopically, each tumor contained a variety of histological patterns; in most instances, a fibrosarcomatous appearance predominated but, within the same tumors, there were areas resembling hemangioma, dilated cysts, an alveolar pattern, osseous foci, and, in peripancreatic tissue, adenocarcinoma. The tumors had ultrastructural features similar to those reported in mesotheliomas in humans; no insulin-like activity was detected. Solid tumors and ascites forms were transplantable for more than 1 generation. The mechanism of oncogenesis by actinomycin D is probably dependent upon the intact peptone lactone moieties and its binding interactions with DNA.

- 0025 THE EFFECT OF BIOMYCIN ON THE INDUCTION OF HEPATIC TUMORS IN MICE. (Rus.) Pyleva, Z. A. (Acad. Med. Sci. USSR, Moscow) and M. Ya. Vysheslavova. *Biull Eksp Biol Med* 69(6):75-77, 1970.

The effect of biomycin on *o*-aminoazotoluene (OAAT) liver carcinogenesis was studied in 405 CBA x C57BL hybrid male mice. OAAT (1% benzene soln) was applied on shaved portions of intercostal skin 3 times weekly for 11 months (130 applications). Biomycin was administered s.c. for 7 days successively (15 mg/kg daily) at different stages of carcinogenesis, starting 1 wk before OAAT treatment and during the 1st, the 6th and the 26th wk of carcinogen application; the control group received no biomycin. Animals receiving biomycin before OAAT application developed tumors 1 month earlier than the control animals and the groups receiving biomycin during the 1st and the 6th week of OAAT application developed tumors 3 months earlier than the control group. Considerable liver tissue alterations (increase of cellular proportions and mitotic figures) were noticed 1 month from the beginning of the experiment. Atypical alterations of the hepatic cell (polynuclear, giant and irregular cells) occurred later; diffused hyperplasia and hepatocytic hypertrophy produced an overall alteration of the liver structure. All tumors revealed the specific structure of hepatocellular carcinoma. Biomycin enhancement of carcinogenesis was attributed to the presence of the growth stimulating vitamin B₁₂ and to the metabolism stimulating characteristics of tetracyclines.

- 0026 DETECTION OF POTENTIAL WEAK CARCINOGENS AND PROCARCINOGENS: II. CARCINOGENICITY OF TERTIARY BUTYL HYDROPEROXIDE. (E.) Hoshino, H. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), G. Chihara and F. Fukuoka. *Gann* 61(2):121-124, 1970.

The effect of topical application of 4-nitroquinoline-1-oxide to female mice and followed by treatment with *t*-butyl-hydroperoxide or *t*-butanol was studied to determine whether the former compound could enhance the carcinogenic activity of the latter 2 compounds. Nine tumors were induced by *t*-butyl-hydroperoxide and only 1 tumor by *t*-butanol when applied after a submanifestational dose of 4-nitroquinoline-1-oxide (20 applications of 0.05 mg in benzene). The difference between the number of tumors produced by these two compounds was statistically significant; the carcinogenicity of *t*-butyl-hydroperoxide is probably due to the production of oxygen-containing free radicals.

0027 TUMORS IN THE URINARY BLADDER OF A MONKEY: INDUCTION WITH 2-NITRONAPHTHALENE. (E.) Conzelman, G. M. (Sch. Vetr. Med., U. California, Davis), J. E. Moulton and L. E. Flanders, III. *Gann* 61(1):79-80, 1970.

2-Nitronaphthalene administration (242 mg/kg p.o.) to a rhesus monkey for 54 months resulted in the formation of numerous papillomas of the urinary bladder when examined at autopsy. The chemical-induced neoplasms were composed of papillae of transitional epithelium which in some areas projected into the underlying lamina propria and submucosa. These epithelial cords showed metaplastic changes, but histopathology consistent with malignancy was not seen. Apparently 2-nitronaphthalene is metabolically reduced in the rhesus monkey and 1 or more of the urinary metabolites has the potential for inducing neoplastic changes in the transitional epithelium of the urinary bladder.

0028 THE EFFECT OF PROLONGED FEEDING OF *ortho*-AMINOAZOTOLUENE ON BINDING TO CELLULAR CONSTITUENTS IN MOUSE LIVER. (E.) Lawson, T. A. (U. Queensland Med. Sch., Herston, Australia). *Chem Biol Interact* 2(1):9-16, 1970.

Female mice received an oral dose of ³H-*o*-aminoazotoluene following a 2-8 wk course of feeding with the unlabeled compound to investigate its binding to nucleic acids and protein in the liver. A rapid decline in the level of binding of labeled material to DNA occurred during the first 2 wk but thereafter the binding remained at a constant level. Binding to protein did not alter significantly during the experiment but there was a continual gradual decline in the binding of labeled material to RNA. Examination of liver DNA, RNA and protein up to 84 days after a single dose of ³H-*o*-aminoazotoluene showed that radioactivity associated with protein could no longer be detected after 28 days whereas that in DNA and RNA was present at 84 days. These results suggest either the existence of a long-lived species of RNA or that the carcinogen stabilizes a species of mouse-liver RNA. Chronic feeding of *o*-aminoazotoluene in the diet for 4 wk reduced the incorporation of ³H-uridine into liver RNA compared with that in untreated mice, although it could not be demonstrated that there was an alteration in the rate of breakdown of RNA.

0029 ELECTRON DENSITY STUDIES ON QUINOLINE ANALOGS OF N,N'-DIMETHYL-*p*-PHENYLAZOANILINE. (E.) Brown, E. V. (Dept. Chem., U. Kentucky, Lexington) and W. H. Kipp. *Cancer Res* 30(8):2089-2090, 1970.

The relationship between electron density and carcinogenic activity of quinoline analogs of *p*-dimethylaminoazobenzene was studied by determining the pK_a of the quinoline nitrogen and the azo nitrogen for the 2-, 3-, 4-, 5-, 6-, 7- and 8-isomers of *p*-dimethylaminophenylazoquinoline. The 5- and 6-isomers which had the highest carcinogenic activity had the highest pK_a values for the amino nitrogen at 2.78 and 2.69, resp., while the other isomers had pK_a's ranging from 0.38-2.39. The pK_a's of the azo nitrogen of the 5- and 6-isomers were 3.36 and 3.37, resp., while the values for the less active isomers fell above and below this narrow range.

0030 BENZENE INDUCED CHROMOSOME ABNORMALITIES IN RAT BONE MARROW CELLS. (E.) Philip, P. (U. Hosp., Copenhagen, Denmark) and M. K. Jensen. *Acta Path Microbiol Scand* 78(4):489-490, 1970.

Rats of both sexes were injected with benzene (2.0 mg/kg, s.c.) 1, 2 and 3 days before sacrifice to determine whether benzene has a direct effect on the chromosome complement of mammalian bone marrow cells. All but 3 treated animals showed an increased number of cell metaphases having structural aberrations consisting exclusively of chromosome breaks, a finding which may suggest that damage occurred in the late S and/or G₂ phases of mitosis. These results indicate that benzene exerts an immediate effect on the chromosomes of mammalian bone marrow cells *in vivo*.

0031 THE RELEVANCE OF CHEMICO-BIOLOGICAL INTERACTIONS FOR THE TOXIC AND CARCINOGENIC EFFECTS OF AROMATIC AMINES: I. CARCINOGENIC ACTIVITY OF SOME 4-AMINOSTILBENE AND 4-AMINOBIENZYL DERIVATIVES. (Ger.) Neumann, H. G. (Max Planck Inst. Biochem., Munich, Germany), M. Metzler, I. Brachmann and C. Thomas. *Z Krebsforsch* 74(2):200-206, 1970.

Stomach-tube-feeding was used to administer 7 amino-stilbene derivatives to rats in an experiment designed to test the carcinogenic activity of these compounds. The known carcinogen trans-4-dimethylaminostilbene (7 μmole twice a week) produced earduct tumors with 100% yields, but equimolar doses of 4-dimethylaminobenzyl and 4-dimethylaminotolane were inactive in 18 months. With cis-4-dimethylaminostilbene no earduct tumors were observed, but weak activity could not be excluded, because one leukemia and one mammary tumor occurred. The chemically reactive derivatives trans-N-hydroxy-4-acetylaminostilbene and trans-N-acetoxy-4-acetylaminostilbene showed the organotropic activity of aminostilbenes in the feeding experiment and produced earduct tumors in females. Although males did not develop any tumors, some died from toxic effects. No carcinogenic or toxic effects were produced by N-acetoxy-4-acetylaminobenzyl.

0032 CANCEROGENIC ALKYLATING SUBSTANCES: III. ALKYL-HALOGENIDES, -SULFATES, -SULFONATES AND STRAINED HETEROCYCLIC COMPOUNDS. (Ger.) Druckrey, H. (Max Planck Inst. Immunobiol., Freiburg, Germany), H. Kruse, R. Preussmann, S. Ivankovic and C. Landschütz. *Z Krebsforsch* 74(3):241-270, 1970.

The carcinogenic efficacy of 12 direct alkylating agents, chosen for chemical reactivity against 4-nitrobenzyl-4-pyridine or for practical use, was tested by administering them s.c., i.v. or p.o., by inhalation, or by the transplacental route to 535 BD-strain rats. S.c. injections once a week of methyl iodide, benzylchloride, dimethyl- and diethyl-sulfate, methyl methanesulfonate, *p*-toluene-sulfonic acid methylester, or trimethylene oxide produced local sarcomas, the yield corresponding to dosage. With di-*n*-butylsulfate, *p*-toluenesulfonic acid ethylester and ethylene sulfide only a few tumors were observed. Veratryl chloride and *p*-toluenesulfonic acid *n*-butylester were not cancerogenic. When given p.o. or by i.v. injections, even dimethyl- and diethyl-sulfate were inactive. Inhalation of dimethyl sulfate vapors, 3 and 10 ppm, resp., for 1 hr 5 times a week, however, produced squamous cell carcinomas of the nasal cavity or neurogenic tumors in 8 of 27 exposed rats. In transplacental experiments a single dose of dimethyl- and diethyl-sulfate was injected into pregnant rats on the 15th day of gestation, with the result that malignant tumors, usually of the nervous system, were developed in 7 out of 59 rats, and in 2 out of 30 of the offspring.

0033 ISLET CELL TUMORS OF THE PANCREAS FOUND IN RATS GIVEN PYRROLIZIDINE ALKALOIDS FROM *AM-SINCKIA INTERMEDIA* FISCH AND MEY AND FROM *HELIOTROPIMUM SUPINUM* L. (E.) Schoental, R. (M. R. C. Toxicol. Unit, Carshalton, Surrey, England), M. E. Fowler and A. Coady. *Cancer Res* 30(8):2127-2131, 1970.

Islet cell tumors of the pancreas developed in rats which had been administered pyrrolizidine alkaloids from *Amsinckia intermedia* Fisch and May (tarweed) and *Heliotropium supinum* Linnaeus, a hepatotoxic Ethiopian plant. One adenoma and 1 adenocarcinoma of the islet cells and 1 adenoma of the exocrine pancreas were found in 3 out of 15 rats given a single dose (500 to 1500 mg/kg) of the pyrrolizidine alkaloids. Among rats treated with *Heliotropium supinum* L., 1 islet cell adenoma was found in 1 of 6 rats given a single dose of its crude alkaloidal fraction (300 mg/kg) and 1 adenocarcinoma in 1 of 2 rats that had the dried plant *H. supinum* in their diet for 1 month. Control rats of ages similar to the test animals did not develop similar tumors.

0034 INFLUENCE OF AGE AND SEX ON CHRONIC THYROIDITIS IN RATS GIVEN SUBCUTANEOUS INJECTIONS OF TRYPTAN BLUE. (E.) Reuber, M. D. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.). *Toxic Appl Pharmacol* 17(1):60-66, 1970.

The influence of age and sex on the incidence of chronic thyroiditis was determined in Buffalo strain rats

(4, 12, 24, and 52 wk of age) given trypan blue (50 mg/kg, s.c. once a wk for 5 wk). Among the female rats the greatest incidence of thyroid lesions occurred in 8-wk-old animals (9/14), 12-wk-old animals (12/14), and 24-wk-old animals (9/14), while among the male rats lesions were more prevalent in 4-wk-old animals (5/12) and 24-wk-old animals (4/12). Thyroiditis was usually moderate in degree (20/37 cases) in female rats and mild (11/19 cases) in males, and severe thyroiditis was observed more often in females (8 cases) than in males (1 case).

0035 EFFECT OF GROWTH OF RHODAMINE SARCOMA IN RAT ON ISOZYMES OF LIVER ENZYMES, WITH REFERENCE TO THE SEESAW CHANGE OF TWO pI-ISOZYMES OF GLUCOSE-6-PHOSPHATE DEHYDROGENASE. (E.) Nakamura, T. (Inst. Protein Res., Osaka U., Japan), Y. Matua, K. Nishikawa, T. Horio and K. Okunuki. *Gann* 61(2):177-190, 1970.

Liver extracts of enzymes from normal and Rhodamine sarcoma-bearing rats were subjected to isoelectric fractionation with Ampholine-carrier ampholytes and divided into their pI-isozymes to investigate the effect of Rhodamine sarcoma growth on liver enzyme isozymes. Glutamate dehydrogenase from normal rats was mostly in a particle-bound form, and divided into at least four fractions of different isoelectric point (pI). The fraction of pI 5.14 (pI 5.14-isozyme) was responsible for most of the total activity, and its activity was hardly influenced by the tumor. There was also a free enzyme, which was so labile as to be totally inactivated during isoelectric fractionation; the activity of the free enzyme was higher in tumor-bearing than normal rats. The enzyme, 6-phosphogluconate dehydrogenase, was resolved into pI 6.16- and pI 6.82-isozymes, and both pI-isozymes were hardly influenced by the tumor until the late stage when pI 6.16-isozyme decreased. Glucose-6-phosphate dehydrogenase was resolved into pI 5.20- and pI 5.90-isozymes; the activity of the former was remarkably higher than the latter in normal rats. With growth of the tumor, the pI 5.20-isozyme decreased and simultaneously pI 5.90-isozyme increased, and the total activity of the two pI-isozymes was not changed by the tumor. The two pI-isozymes of glucose-6-phosphate dehydrogenase showed a strict specificity on glucose 6-phosphate and NADP⁺; neither galactose-6-phosphate nor fructose-6-phosphate acted as a substrate, and NAD⁺ was not substituted for NADP⁺. The *K_m* values of pI 5.20-isozyme and pI 5.90-isozyme were 1.5×10^{-5} M and 6.9×10^{-5} M, resp., for glucose 6-phosphate and 8.4×10^{-6} M and 1.2×10^{-5} M, resp., for NADP⁺.

0036 THE POSSIBLE CARCINOGENIC PROPERTIES OF ALTERED LIPIDS: A STUDY OF PURIFIED COMPOUNDS BY THE NEWT TEST. (E.) Glavind, J. (Central Hosp., Hjørring, Denmark) and E. Arffman. *Acta Path Microbiol Scand* 78(3):345-350, 1970.

The newt test was used as a short-term test for the study of the possible carcinogenic effects of methyl oleate, methyl linoleate and several of their derivatives. The substances were tested in serial dilu-

tions in order to establish dose-response relationships. The most actively necrosis-producing compound was methyl 12-oxo-*trans*-10-octadecenoate. The esters of oleate and linoleate hydroperoxide and the corresponding hydroxy-compounds, obtained by reduction of the hydroperoxides, were also active. Conjugation of the double bonds in linoleic acid gave a weak activity, and the compounds obtained by *trans*-isomerization of the double bonds in oleic and linoleic acid were estimated as inactive. Moderate activity resulted from the introduction of a hydroperoxide or a hydroxyl group in the α -position to a double bond but not in the β -position. The susceptibility of the new to carcinogenic compounds is subject to seasonal variation, with susceptibility increasing in the fall; this factor constitutes an inconvenience attending use of the new test for carcinogenicity.

- 0037 INDUCTION, HISTOGENESIS, AND ISOTRANS-PLANTABILITY OF RENAL TUMORS INDUCED BY FORMIC ACID 2-[4-(5-NITRO-2-FURYL)-2-THIAZOLYL]-HYDRAZIDE IN RATS. (E.) Erturk, E. (U. Wisconsin Med. Sch., Madison), S. M. Cohen and G. T. Bryan. *Cancer Res* 30(8):2098-2106, 1970.

Formic acid 2-[4-(5-nitro-2-furyl)-2-thiazolyl]hydrazide-induced renal tubular tumors (0.2% in diet for 46 wk), including cortical (tubular) adenomas, low-grade renal tubular carcinomas, and highly malignant renal tubular carcinomas were transplanted s.c. into weanling female rats to test the malignant potential of these tumors. The chemically induced, small, histologically benign, cortical adenomas demonstrated the same characteristics of cancer as renal tubular carcinomas after 3 serial transplantations. All histologically different tumor lines had the same latent periods, rapid growth rates, and identical histological features with high mitotic activity and extreme cellular pleomorphism when compared with the solid cellular tubular carcinomas. Apparently, formic acid 2-[4-(5-nitro-2-furyl)-2-thiazolyl]hydrazide induces tumors which have many of the properties of cancer and which may be regarded as carcinomas, although they appear benign.

- 0038 COMPARATIVE URINARY AND GALLBLADDER CARCINOGENICITY OF N-[4-(5-NITRO-2-FURYL)-2-THIAZOLYL]FORMAMIDE AND N-[4-(5-NITRO-2-FURYL)-2-THIAZOLYL]-ACETAMIDE IN THE DOG. (E.) Erturk, E. (U. Wisconsin Med. Sch., Madison), S. A. Atassi, O. Yoshida, S. M. Cohen, J. M. Price and G. T. Bryan. *J Nat Cancer Inst* 45(3):535-542, 1970.

Six dogs, in 2 groups of 4 and 2, were fed, resp., N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide and N-[4-(5-nitro-2-furyl)-2-thiazolyl]acetamide, for 2 and 2½ yr, followed by 9 months on a normal diet; the former compound is a urinary bladder carcinogen in mice and rats, the latter a carcinogen for breast, salivary gland, lung and kidney pelvis of the rat and a murine leukemogen. With N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide, all dogs developed transitional cell carcinoma; half of the dogs developed ureteral transitional cell carcinoma and renal pelvis transitional cell carcinoma. All developed gallbladder

adenocarcinoma and half developed mammary scirrhous carcinoma and mammary fibroadenoma. With N-[4-(5-nitro-2-furyl)-2-thiazolyl]acetamide, all dogs developed gallbladder adenoma and mammary fibroadenoma. The seemingly minor structural difference of the compounds significantly altered the distribution and degree of severity of the tumors.

- 0039 RNA AND AMINE SYNTHESIS IN THE LIVER OF RATS GIVEN INJECTIONS OF THIOACETAMIDE. (E.) Fausto, N. (Div. Biol. Med. Sci., Brown U., Providence, R. I.). *Cancer Res* 30(7):1947-1952, 1970.

The effect of thioacetamide on nuclear RNA metabolism and amine synthesis was investigated in liver homogenates of male rats pretreated with 50-150 mg/kg of the compound (i.p.). A single injection of the drug caused a 38-60-fold increase in ornithine decarboxylase activity which peaked at 24 hr, and a 1.5 to 2.0-fold stimulation of the labeling of nuclear RNA. Puromycin (100 mg/kg) and actinomycin D (2 mg/kg) injections inhibited ornithine decarboxylase activity in thioacetamide-treated rats. Repeated injections of thioacetamide caused accumulation of RNA in the nucleus, increase in the amount of spermidine, and a small decrease in spermine. Organ hypertrophy and increased liver RNA are apparently fostered by parallel changes in RNA and amine metabolism, under experimental conditions.

- 0040 ACCELERATED INDUCTION OF HEPATOMA IN RATS FED N,N'-2,7-FLUORENYLENEBISACETAMIDE BY X-IRRADIATION TO THE TARGET AREA. (E.) Nagayo, T. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan), M. Ito and S. Yamada. *Gann* 61(1):81-83, 1970.

The effects of N,N'-2,7-fluorenylenebisacetamide feeding and X-irradiation on hepatoma growth were studied in Buffalo rats. In macroscopical and microscopical examinations, hepatoma nodules were found within the area exposed to irradiation. Livers of animals fed continuously with N,N'-2,7-fluorenylenebisacetamide were the same as livers of animals with the same diet which were also irradiated. Observations revealed an unstable state of liver parenchyma such as bile ductule proliferation along Glisson's sheath, nodular hyperplasia, cholangiofibrosis, and foci composed of basophilic small hepatic cells, but no malignant changes were observed. The group receiving only X-irradiation alone was found normal, histologically. The duration of the carcinogen feeding was 27 weeks and at this time, no hepatoma was observed in either sex.

- 0041 EFFECTS OF ISOMERS OF ACETOTOLUIDIDE AND AMINO BENZOIC ACID ON THE TOXICITY AND CARCINOGENICITY OF N-2-FLUORENYLACETAMIDE. (E.) Yamamoto, R. S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda Md.), H. H. Frankel and J. H. Weisburger. *Toxic Appl Pharmacol* 17(1):98-106, 1970.

The *o*-, *m*-, and *p*-isomers of acetotoluidides and aminobenzoic acids were fed to rats at a 44-fold molar

excess dose, to test the inhibitory effect of these agents on carcinogenesis induced by *N*-2-fluorenylacetyl- amide. All 6 compounds tested prevented the death of male Fischer rats due to the toxic action of 300 ppm *N*-2-fluorenylacetyl- amide. However, only *m*-acetotoluidide and *m*-aminobenzoic acid inhibited the carcinogenic effect of *N*-2-fluorenylacetyl- amide, as did acetanilide. *p*-Aminobenzoic acid had a weak inhibitory effect since no hepatomas, but only hyperplastic nodules, were seen. *o*-Acetotoluidide was quite toxic by itself, producing enlarged livers with marked hydropic swelling and fatty changes, whereas *o*-aminobenzoic acid (anthranilic acid) did not lead to liver changes. Hepatoma induction by *N*-2-fluorenylacetyl- amide was not affected by either the two *o*-substituted toluidine derivatives or *p*-acetotoluidide.

- 0042 THE EFFECTS OF 2-ACETYLAMINOFLUORENE AND NITRITE ON FREE RADICALS AND CARCINOGENESIS IN RAT LIVER. (E.) Commoner, B. (Dept. Botany, Washington U., St. Louis, Mo.), J. C. Woolum, B. H. Senturia, Jr. and J. L. Ternberg. *Cancer Res* 30(8): 2091-2097, 1970.

The relationship of the abnormal electron spin resonance signal seen in livers of carcinogen-fed rats to carcinogenesis was investigated. The $g = 2.035$ signal was observed when rats were fed 2-acetylaminofluorene or *p*-dimethylaminoazobenzene in a synthetic (defined and low-protein) diet with 1.6 mg/l of nitrite nitrogen in drinking water, but the signal was absent if the carcinogen was fed in a standard laboratory chow with 32 mg/l of nitrite nitrogen as drinking water. Rats maintained on 2-acetylaminofluorene in synthetic diet and distilled water showed an almost 100% incidence of liver tumors, while animals maintained on 2-acetylaminofluorene on laboratory chow diet had a 50% incidence of tumors. The addition of nitrite to both diets containing the carcinogen decreased the tumor incidence to 63% and 32% in the synthetic and laboratory chow diets, resp. The free radical complex (probably due to a ferrous iron, nitric oxide and a thiol protein complex) appears to be related to a decrease in the carcinogenicity of 2-acetylaminofluorene; the complex formation with cellular thiols may be competitive with that of carcinogen binding to protein thiols.

- 0043 HYDRAZINE TOXICITY IN PREGNANT RATS. (E.) Lee, S. H. (Path. Inst., McGill U., Montreal, Quebec, Canada) and H. Aleyassine. *Arch Environ Hlth* 21(5): 615-619, 1970.

Pregnant female rats were administered s.c. injections of neutralized hydrazine (8 mg/kg/day) for 10 days to assess the toxicity of this compound during pregnancy. The body wt of these treated rats dropped continuously during the experimental period. Fetuses which were examined prior to delivery by termination of pregnancy were characterized by their small size, pallor, and generalized edema, with occasional petechiae. The prenatal and perinatal mortality was 100%. Administration of pyridoxine hydrochloride at 200 mg/kg/day maintained a steady gain of body wt in the pregnant rats but only resulted in partial protection of the fetuses. Intra-

uterine life appears to be more susceptible to hydrazine toxicity than the adult life, and the pathogenesis of the toxicity may be associated with mechanisms other than pyridoxine inhibition.

- 0044 THE EARLY STAGES OF THE 1,2-DIMETHYLHYDRAZINE-INDUCED CARCINOMA OF THE SMALL AND LARGE INTESTINE OF RATS. (Ger.) Springer, P. (Path. Inst. U. Freiburg, Germany), J. Springer and W. Oehlert. *Z Krebsforsch* 74(3):236-240, 1970.

The morphology of intestinal cells in rats undergoing a course of weekly s.c. injections of 21 mg/kg of 1,2-dimethylhydrazine was examined during the early stages of development of intestinal papillomas and carcinomas. In 12 of 77 rats adenocarcinomas developed in the large intestine between the 10th and 16th week after starting the injections. In the same groups 3 carcinomas and 21 papillomas of the small intestine were detected histologically. Autoradiographic investigations after application of ^{34}S -sulfate and ^3H -thymidine revealed alterations of the mucosa of the large intestine characterized by a decrease in the number of mucous secreting cells between the 5th and 12th week of the course of injections. The differentiation of basal epithelial cells in the same region increased, producing an enlargement of the proliferation zone which extended from the bottom of the crypts up to the surface of the mucosa. The labeling index increased 3-fold compared to the normal, and in the small intestine the dedifferentiation zone, being normally identical with the crypts of Lieberkühn, extended the length of the villi. The epithelial cells of the tips of the villi showed a high proliferating activity and a loss of cellular differentiation.

- 0045 EFFECT OF AFLATOXIN B_1 UPON PHYTOHEMAGGLUTININ-TRANSFORMED HUMAN LYMPHOCYTES. (E.) Savel, H. (U. Vermont Coll. Med., Burlington), D. Forsyth, W. Schaeffer and T. Cardella. *Proc Soc Exp Biol Med* 134(4):1112-1115, 1970.

The effects of aflatoxin B_1 on *in vitro* transformation of human peripheral blood lymphocytes by phytohemagglutinin and specific antigens were investigated. Lymphocyte cultures from peripheral blood samples obtained from volunteers containing aflatoxin B_1 , 1.6 $\mu\text{g}/\text{ml}$ in 3% DMSO, and phytohemagglutinin-M, with appropriate controls, were incubated with 50 μC ^3H -thymidine from days 5 to 6 of culture and harvested by filtration on Millipore membranes. The addition of aflatoxin B_1 to phytohemagglutinin-stimulated cultures of human peripheral blood lymphocytes resulted in an inhibition of thymidine uptake as compared to control cultures; the addition of 3% DMSO had no effect on thymidine uptake control cultures. Thymidine uptake in PPD-exposed lymphocyte cultures from a patient who was tuberculin positive was inhibited 62% by incubation with 50 $\mu\text{g}/\text{ml}$ aflatoxin B_1 ; similar inhibition was observed in mumps antigen-exposed lymphocyte cultures from a patient who was mumps-sensitive. When the cultures incubated with phytohemagglutinin and aflatoxin B_1 for up to 4 hr were harvested and the cells washed and placed in new media containing only phytohemagglutinin, the inhibitory effect on

thymidine uptake was not seen. Aflatoxin B₁ apparently blocks a pathway common to both antigenic and phytohemagglutinin stimulation.

0046 LIVER NUCLEAR RNA METABOLISM IN RATS
TREATED WITH AFLATOXIN B₁. (E.)

Friedman, M. A. (Child. Cancer Res. Found., Boston, Mass.) and J. N. Wogan. *Life Sci* 9(13):741-747, 1970.

The dose-dependency characteristics of aflatoxin B₁ inhibition of rat liver polymerase and suppression of precursor incorporation into 28S and 18S nuclear RNA was studied. Liver cell nuclei were isolated from rats treated with 0.5, 1.0 or 3.0 mg/kg aflatoxin B₁, $\frac{1}{2}$, 24 or 48 hr before sacrifice and ¹⁴C-orotate 1 hr before sacrifice. Inhibition of RNA polymerase activity was dose-dependent, rapid and lasted for at least 48 hr; at 5 min after treatment with aflatoxin B₁, there was a 50% inhibition of RNA polymerase activity at each of several levels of ammonium sulfate ranging from 0 to 0.32 M. Nuclear RNA density gradient sedimentation profiles and distribution of radioactivity in fractions of liver nuclear RNA isolated from rats treated with 0.5 mg/kg aflatoxin B₁ showed a marked inhibition of orotate uptake into 28S and 18S nuclear RNA. The alteration of orotate incorporation became progressively more pronounced until all incorporation had virtually ceased by 12 hr after treatment. The relationships of acute responses to aflatoxin B₁ such as these to the mechanisms involved in the chronic response, carcinogenesis, remain to be elucidated.

0047 INTERACTION OF AFLATOXINS B₁ AND G₁ WITH
TISSUES OF THE RAT. (E.) Lijinsky, W.
(U. Nebraska Coll. Med., Omaha), K. Y. Lee and C. H. Gallagher. *Cancer Res* 30(8):2280-2283, 1970.

Groups of female rats were injected i.p. with a solution containing either 1.25 or 0.5 mg of tritium labeled aflatoxin B₁ or G₁ to investigate the incorporation of the carcinogenic aflatoxins into DNA, RNA, and soluble protein of liver, kidney, spleen and intestines. The variation of the amount of incorporation of labeled compound with time was monitored by isolation of nucleic acids and proteins from animals killed 1 hr, 6 hr, 18 hr, 1 week, 4 weeks, and 8 weeks after being given an injection of the labeled aflatoxins. Maximal incorporation of radioactivity into all 3 components of the 4 organs was found between 6 and 18 hr after injection. With both aflatoxins, a progressive decline in specific activity of nucleic acids and protein of the 4 organs was observed from 18 hr to 8 weeks. The highest specific activity with aflatoxin B₁ was in the liver protein at 6 hr, which contained 10% of the injected radioactivity; with aflatoxin G₁, the highest specific activity was in liver RNA at 18 hr. Labeling of kidney and spleen protein was particularly persistent with both aflatoxins, and the radioactivity appeared to be covalently bound to protein. No correlation in the binding of the 2 aflatoxins to DNA, RNA or protein in the various organs and the

higher carcinogenic potency of aflatoxin B₁ compared to aflatoxin G₁ was seen.

0048 STUNTED PIGS FROM SOWS FED CRUDE AFLATOXINS.
(E.) Cardeilhac, P. T. (Dept. Vetr. Sci.,
U. Florida, Gainesville), E. C. Schroeder, J. T.
Perdomo, G. E. Combs and G. T. Edds. *Toxic Appl
Pharmacol* 17(2):548-550, 1970.

A study designed to determine the effects on suckling pigs of aflatoxin administration to the nursing mother is reported. Two sows which had nursing pigs were fed 0.234 and 0.077 mg, resp., of aflatoxin per kg body wt over a 4-day period immediately following parturition. The sow which received the higher level of aflatoxin was sluggish and some serum enzyme values were elevated. Lesions in pigs nursing the sows given aflatoxin, detectable by the methods utilized in these experiments, were mild; however, the pigs from these sows gained weight at distinctly lower rates than control pigs. The stunting was clearly evident by weaning time and persisted until time of slaughter with no compensatory growth seen after weaning. The stunting probably resulted from a transmission of toxin in the milk of the sow to the pigs, rather than from decreased milk production or some other toxic effect on the sow itself.

0049 THE REVERSIBILITY OF INHIBITION OF RNA AND
DNA SYNTHESIS INDUCED BY AFLATOXIN IN RAT
LIVER: A TENTATIVE EXPLANATION FOR CARCINOGENIC
MECHANISM. (E.) Lafarge, C. (Inst. Res. Sci. Cancer,
Villejuif, France) and C. Prayssinet. *Int J Cancer*
6(1):74-83, 1970.

Partially hepatectomized male rats were inoculated i.p. with aflatoxin (250-1000 µg/kg) and subsequently administered 6-¹⁴C-orotic acid to monitor RNA and DNA synthesis. Progressive changes which occurred within a few hr after aflatoxin administration were inhibition of nucleolar RNA synthesis, followed by inhibition of replication and, finally, inhibition of total nuclear transcription. These phenomena were reversible, and the different syntheses recommenced in the following order: after 24 hr total nuclear RNA synthesis was followed by nucleolar RNA synthesis, and DNA synthesis resumed after 48 hr, so that there was a period of at least 24 hr during which RNA was synthesized and DNA was not. The mechanism for the carcinogenic action of aflatoxin may be due to the binding of aflatoxin or one of its metabolites to DNA, with consequent genetic deletions which may lead to malignant transformation.

0050 ON PROTEIN TARGETS OF CHEMICAL CARCINOGENS:
DISSIMILAR MOLECULAR SIZES OF THE PRINCIPAL
PROTEIN CONJUGATES. (E.) Sorof, S. (Inst. Cancer Res.,
Fox Chase, Philadelphia, Pa.), E. M. Young, R. A.
McBride and C. B. Coffey. *Cancer Res* 30(7):2029-
2034, 1970.

The soluble liver protein-carcinogen conjugates produced by feeding 3'-dimethyl-4-dimethylaminoazobenzene (0.058% of diet) or N-2-fluorenylacetamide

0.036% of diet) to adult male rats were resolved and analyzed according to molecular size. The molecular sizes of the principal soluble conjugates of three types of carcinogens were compared in order to deduce whether they originate from a common or similar target protein. The principal conjugate found in the livers of rats given 3'-methyl-4-dimethylaminoazobenzene for 18-21 days consisted of 62% of the soluble protein-bound dyes, belonged to the 5 S class of macromolecules, and was of 60,000 to 80,000 molecular wt. A minor azoprotein (19%) was a 4 S macromolecule (30,000 to 40,000) and was apparently the basic conjugate previously separated on the basis of charge. Small amounts of azo dyes (~5%) were bound to the 2 S (10,000 to 15,000) and ~7.5 S (~150,000) macromolecules. The 7.5 S macromolecule conjugates in livers of rats given *N*-2-fluorenylacetylamide for 5 wk (~150,000) consisted of 40% of the soluble protein-bound Fluorenyl-¹⁴C, and apparently contained the previously described principal charge species, fast and/or slow fluorenyl-¹⁴C-proteins. Each of the other classes of soluble macromolecules had considerably less conjugate. This diversity in molecular wt of the principal isolated conjugates indicates that the target proteins of the 2 carcinogens either are different at least in molecular size or, if identical, are altered in different ways as a result of interaction with the carcinogens.

0051 DIETARY INDUCTION OF SOME ENZYMES OF AMINO ACID METABOLISM FOLLOWING THE ACUTE ADMINISTRATION OF AMINOAZO DYES. (E.) Poirier, L. A. (Hosp. Notre Dame, Montreal, Quebec, Canada) and H. C. Pitot. *Cancer Res* 30(7):1980-1985, 1970.

The effects of 3'-methyl-4-dimethylaminoazobenzene, 2-methyl-4-monomethylaminoazobenzene and *N*-benzoyloxy-4-monomethylaminoazobenzene on the dietary responses of 5 hepatic enzymes, serine dehydratase, histidase, ornithine- δ -transaminase, tryptophan pyrrolase, and tyrosine- α -ketoglutarate transaminase were investigated. Dietary induction was effected by the forced feeding of casein hydrolysate to protein-depleted adult male rats. The i.p. administration of each of the compounds 3 hr prior to the intubation of casein hydrolysate completely inhibited the dietary response of histidase and partially repressed that of serine dehydratase. The metabolic response of ornithine- δ -transaminase was partially repressed by the acute administration of 3'-methyl-4-dimethylaminoazobenzene (50 mg) and 2-methyl-4-dimethylaminoazobenzene (50 mg), but not by *N*-benzoyloxy-monomethylaminoazobenzene (2 mg). Tyrosine- α -ketoglutarate transaminase induction presented an anomalous situation; the injection of 3'-methyl- or 2-methyl-4-dimethylaminoazobenzene 3 hr before enzyme induction had no statistically significant effect upon the induced enzyme level, while *N*-benzoyloxy-4-monomethylaminoazobenzene injected at the same time significantly increased the induced enzyme level. A complete or partial inhibition by 3'-methyl-4-monomethylaminoazobenzene of the induction of serine dehydratase, histidase, and ornithine- δ -transaminase was observed following injection of the dye 16 or 3 hr before, at the same time as, or 3 and 8 hr after the initial intubation of casein hydrolysate. The

injection of dye 16 hr before the start of enzyme induction appeared to inhibit the induction of tyrosine- α -ketoglutarate transaminase; at no time did any of the dyes investigated have a significant effect on the adaptive response of tryptophan pyrrolase. A comparison of these results with the known times of template stability for each of these enzymes suggests that it is during the translational period of enzyme synthesis that 3'-methyl-4-monomethylaminoazobenzene exerts its effects.

0052 METABOLIC ADAPTATIONS DURING HEPATOCARCINOGENESIS: DIETARY INDUCTION OF SOME ENZYMES OF CARBOHYDRATE METABOLISM DURING 3'-METHYL- AND 2-METHYL-N,N-DIMETHYL-4-AMINOAZOBENZENE FEEDING. (E.) Poirier, L. A. (Hosp. Notre Dame, Montreal, Quebec, Canada) and H. C. Pitot. *Cancer Res* 30(7):1974-1979, 1970.

The effects of 0.054% 3'-methyl-4-dimethylaminoazobenzene or 0.054% 2-methyl-4-dimethylaminoazobenzene in the diet following a 3-day fast and a 27-hr re-feeding period with a 30% protein diet on the dietary induction of glucokinase, glucose-6-phosphate dehydrogenase, 6-phosphogluconate dehydrogenase, malic enzyme, and citrate cleavage enzyme were investigated. The metabolic responses of all of the enzymes studied were found to be absent or diminished in the animals fed the 3'-methyl-4-dimethylaminoazobenzene diet for 3 to 5 weeks. Except for 6-phosphogluconate dehydrogenase, the adaptation of which was found to be slightly diminished at the end of 5 weeks of administration of the basal diet the metabolic responses of each of the enzymes in the control animals remained essentially normal throughout the experimental period. The chronic administration of the noncarcinogenic dye, 2-methyl-4-dimethylaminoazobenzene, appeared to produce a loss in the inducibility of 6-phosphogluconate dehydrogenase, a diminished response of glucose-6-phosphate dehydrogenase, and no effect on the metabolic adaptations of the other 3 enzymes investigated. Feeding 3'-methyl-4-dimethylaminoazobenzene appeared to produce an increase in the base level of glucose-6-phosphate dehydrogenase and a marked decrease in the base levels of glucokinase and malic enzyme; the base levels of this latter enzyme were also diminished in the livers of rats fed either 2-methyl-4-dimethylaminoazobenzene or the basal diet. The base levels of all of the other adaptive enzymes tested appeared to be unaffected by any of the diets used in these experiments. The data indicate that, as with rats fed 2-acetylaminofluorene, the normal metabolic responses of the enzymes of carbohydrate metabolism were lost or diminished in the livers of rats fed 3'-methyl-4-dimethylaminoazobenzene.

0053 THE ISOLATION OF NORMAL RAT LIVER *h* PROTEINS AND THE IMMUNOLOGICAL REACTIONS OF MOUSE ANTI-RAT LIVER *h* PROTEIN. (E.) Louis, C. J. (Dept. Path., U. Melbourne, Australia) and J. M. Blunck. *Cancer Res* 30(7):2043-2048, 1970.

Rat liver *h* proteins were isolated from normal rat liver and used to prepare an antibody from mice which was used to study the antigenic proteins from normal, preneoplastic and neoplastic rat liver.

This antibody reacted with normal rat liver *h* proteins and with soluble liver azoproteins from rats fed 3'-methyl-4-dimethylaminoazobenzene but did not react with other soluble proteins from dye-induced rat liver tumors. Immunoelectrophoretic and gel double-diffusion procedures have demonstrated the identity of these *h* proteins with those deleted during azo dye carcinogenesis. The decrease in *h* protein in azo dye-induced carcinomata and the demonstration that an *h* protein antigen cross-reacted with 27% of the azoproteins formed following azo dye administration suggest that the *h* proteins might be a target of the azocarcinogens.

- 0054 EFFECT OF DIETARY RIBOFLAVIN ON AZO DYE REDUCTASE IN LIVER AND IN BACTERIA OF CECAL CONTENTS OF RATS. (E.) Williams, J. R., Jr. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), P. H. Grantham, R. S. Yamamoto and J. H. Weisburger. *Biochem Pharmacol* 19(8):2523-2525, 1970.

The possibility that the bacterial flora in the lower intestinal tract of rats might participate in the metabolism of the carcinogenic azo dye, 4-dimethylaminoazobenzene, was investigated. Azo dye reductase activity was determined in cecal contents and liver homogenates of rats maintained for 6 weeks on a low casein (12%) and low riboflavin (2 ppm) diet or low casein diets to which additional riboflavin was added to give 20 and 200 ppm. With the 2 ppm riboflavin diet, the azo dye reductase activity of the liver was 3.3 nmoles/mg/30 min and 32.7 nmoles/mg/30 min for the cecal contents. Supplementation of the assay mixture *in vitro* with riboflavin raised the activity of both the liver and cecal contents by 16 nmole/mg/30 min. The riboflavin-supplemented diets increased the liver azo dye reductase 7 to 8-fold and the bacterial azo dye reductase by 20-50%. The participation of enzymes provided by the intestinal bacterial flora needs to be considered in studies of the overall fate of exogenous materials in mammalian systems, especially in cases where the compound is either fed orally or secreted into the intestinal tract via the bile.

- 0055 CARCINOGENICITY AND TARGET ORGANS OF METHOXYL DERIVATIVES OF 4-AMINOAZOBENZENE IN RATS: II. EFFECT OF VARIOUS CONCENTRATION OF 3-METHOXY- AND 2,5-DIMETHOXY-4-AMINOAZOBENZENE IN THE DIET. (E.) Odashima, S. (Sasaki Inst., Tokyo, Japan) and Y. Hashimoto. *Gann* 61(2):153-160, 1970.

Two carcinogens, 3-methoxy- and 2,5-dimethoxy-4-aminoazobenzene were administered continuously to male rats (0.09, 0.04, and 0.025% of diet) to assess the tumorigenic properties of these compounds. Liver tumors developed in nearly all of the rats given 3-methoxy-4-aminoazobenzene, but 2,5-dimethoxy-4-aminoazobenzene was essentially non-carcinogenic although 8 times more toxic than the former compound. More extrahepatic tumors were observed in the rats given 0.09% 3-methoxy-4-aminoazobenzene than in those given 0.04% or 0.025% 3-methoxy-4-aminoazobenzene. Among 26 animals receiving 0.09% 3-methoxy-4-aminoazobenzene, tumors of the spleen

and ear duct developed in 3 animals and tumors of the skin and small intestine in 2. With the lower concentrations of 3-methoxy-4-aminoazobenzene, only 2 animals out of 46 developed tumors of the spleen.

- 0056 THE FATE OF N-ALKYL GROUPS IN THE COURSE OF BINDING OF METABOLITES OF SEVERAL N-ALKYL AMINO AZO DYES TO RAT-LIVER PROTEINS. (E.) Matsumoto M. (Fac. Sci. U. Tokyo, Japan) and H. Terayama. *Chem Biol Interact* 2(1):41-45, 1970.

The specific radioactivities of polar dyes prepared from livers of rats 40 hr after administration of N-alkyl-4-aminoazobenzene derivatives (25 mg) in which 1 or the other or both of the N-alkyl substituents had been ^{14}C -labeled, were compared with those of the original azo dyes. The presence of 1 alkyl group was essential for binding to occur; and a metabolite with an N-methyl group was bound preferentially to one with an N-ethyl group. Polar dyes from rats given ^3H and ^{14}C doubly labeled N-methyl-4-aminoazobenzene have the same radioactivity ratios as that of the original non-polar dye, which indicates that the azo dye does not bind at the N-methyl carbon atom, although the presence of the N-methyl group seems to be essential for binding.

- 0057 TUMOR-INDUCED SKIN HETEROGENIZATION: I. RECIPROCAL RELATIONSHIP BETWEEN TUMORS AND SKIN GRAFTS. (E.) Mkheidze, D. M. (Min. Hlth. Georgian SSR, Tbilisi, USSR), A. L. Liozner and G. J. Svet-Moldavsky. *J Nat Cancer Inst* 45(3):465-473, 1970.

Strain-specific tumors were induced in mice and hamsters by i.m. injections of 7,12-dimethylbenz(a)-anthracene to test the reciprocal effect of transplantable tumors and syngeneic or allogeneic skin grafts. When allogeneic skin was grafted to mice before, simultaneously, or after syngeneic tumor implantation, the growth rate of the tumor was unchanged; grafts, taken from tumor-bearing mice, were regularly rejected by normal syngeneic recipients; patterns of rejection were similar to those of common allotransplantation reaction. The rejection of the skin graft may have been caused by the appearance of a new transplantation-type antigen in the skin, which was recognized by an immune mechanism both in syngeneic and allogeneic grafting. Skin grafts, taken from mice that had rejected a skin transplant derived from a tumor-bearing donor, were also rejected in syngeneic transplantation. The "heterogenization state" was successively passed by means of skin transplantation 12 times. Mouse sarcomas induced by 7,12-dimethylbenz(a)anthracene produced skin heterogenization only after being transplanted at least once in syngeneic animals; the skin of primary tumor hosts did not appear to be heterogenized.

- 0058 THE EFFECTS OF 7,12-DIMETHYLBENZ(a)ANTHRACENE ON THE SYNTHESIS OF NUCLEIC ACIDS IN RAPIDLY DIVIDING HEPATIC CELLS IN RATS. (E.) Marquardt, H. (Pharmacol. Inst., U. Cologne, Germany) and F. S. Philips. *Cancer Res* 30(7):2000-2006, 1970.

Young adult rats were partially hepatectomized and injected with an i.v. emulsion of 7,12-dimethylbenz(a)anthracene (25 mg/kg) to investigate the effect of this carcinogen on regenerating liver. The compound administered 24 hr after hepatectomy caused transient (24hr) suppression of regenerative growth, an effect which may be related to carcinogenic activity. The suppression effect was shown by a decrease in mitotic index and inhibition of increases of cell number and total DNA. Similar doses inhibited the incorporation of thymidine-2-¹⁴C and orthophosphate-³²P into DNA of regenerating liver and rapidly growing liver in intact immature rats. The inhibition was evident within 2 hr, maximal by 6 to 12 hr, and no longer present at 24 hr; it was dose dependent and not prevented by adrenalectomy. The incorporation of ¹⁴C-6-orotic acid into rRNA was unaffected. Similar data were obtained when the carcinogen was administered 5 hr after hepatectomy, prior to the onset of DNA synthesis in the regenerating liver. Histological examination of animals treated with 7,12-dimethylbenz(a)anthracene showed no abnormalities. The findings were consistent with a suggestion that 7,12-dimethylbenz(a)anthracene affects DNA primarily in cells in the S phase of the mitotic cycle, possibly by binding to the macromolecule and thus inhibiting its synthesis.

0059 TUMORIGENESIS IN MOUSE SKIN: INHIBITION BY SYNTHETIC INHIBITORS OF PROTEASES. (E.) Carroll, W. (New York U. Med. Ctr., New York), A. Klassen and A. Janoff. *Science* 169(3951):1211-1213, 1970.

Tumorigenesis was initiated in mice by means of exposure to 7,12-dimethylbenz(a)anthracene and promoted with phorbol ester or croton oil to test the inhibition of tumor formation in mouse skin by 3 synthetic inhibitors of proteases: tosyl lysine chloromethyl ketone, tosyl phenylalanine chloromethyl ketone, and tosyl arginine methyl ester. The protease inhibitors were applied in DMSO 3 times weekly in 1.0 µg doses 1-2 hr after croton oil. After 30 wk on promotion, 11 out of 19 control animals (DMSO alone) developed tumors, while only 1 out of 21 animals treated with tosyl phenylalanine chloromethyl ketone, 5 out of 21 animals treated with tosyl lysine chloromethyl ketone and 5 out of 21 animals treated with tosyl arginine methyl ester developed tumors. Some of the irritant effects of the promoter substances were also alleviated by the protease inhibitors.

0060 HORMONE RESPONSIVENESS OF THE TRANSPLANTED TUMORS OBTAINED FROM DMBA-INDUCED MAMMARY TUMORS. (E.) Takahashi, T. (Kyoto Prefect. Coll. Med., Japan) and W. L. Simpson. *Tohoku J Exp Med* 101(1):93-102, 1970.

Male and female rats received transplanted mammary tumors which had originally been induced by 7,12-dimethylbenz(a)anthracene (2.5 mg x 2) to investigate the responsiveness of these tumors to different hormonal environments. Two primary tumors were successfully transplanted into castrated rats receiving estradiol (100 µg) or progesterone (5 mg), and

showed strong hormone responsiveness. The transplanted tumors regressed after withdrawing the hormone, and injection of estradiol and progesterone brought about tumor regrowth after a long period of dormancy. The hormone responsiveness was lost by serial transplantation and metastasis occurred in rats with the hormone-independent tumor. The histologic appearance of the transplanted tumors was greatly altered by hormone; the tumor receiving estradiol showed plump epithelial cells with conspicuous vacuoles and large lumina of acini containing milk-like material. The tumor receiving progesterone displayed fine acini composed of thin epithelial cells, and the regressed tumor exhibited cystic spaces outlined by a single layer of flattened epithelial cells.

0061 CHANGES IN CHROMOSOMES OF BONE MARROW AFTER INTRAVENOUS INJECTIONS OF 7,12-DIMETHYLBENZ(a)ANTHRACENE AND RELATED COMPOUNDS. (E.) Rees, E. D. (U. Kentucky Med. Ctr., Lexington), S. K. Majumdar and A. Shuck. *Proc Nat Acad Sci* 66(4):1228-1235, 1970.

A high incidence of leukemia was induced in rats by i.v. injection (40 mg/kg) of an emulsion containing 7,12-dimethylbenz(a)anthracene (5 mg/ml) or 7,8,12-trimethylbenz(a)anthracene (same dose and same emulsion), with 50% of metaphasic marrow cells showing chromosomes with breaks 24 hr after treatment. Although breaks were inflicted on chromosomes of various sizes and morphology, these aberrations were nonrandom in that members of the nos. 1 and 2 chromosome pairs were involved to an extent greater than expected on the basis of their size and number. Distinctive karyotypic abnormalities involving the no. 2 chromosome were observed in half of the leukemic rats, whereas these abnormalities were not observed in nonleukemic 7,12-dimethylbenz(a)anthracene-treated rats. Fewer breaks in the no. 2 chromosome, and in others, were produced by benzo(a)pyrene and benzo(e)pyrene.

0062 EFFECT OF DIETARY FAT AND DOSE LEVEL OF 7,12-DIMETHYLBENZ(a)ANTHRACENE ON MAMMARY TUMOR INCIDENCE IN RATS. (E.) Carroll, K. K. (Dept. Biochem., U. Western Ontario, London, Canada) and H. T. Khor. *Cancer Res* 30(8):2260-2264, 1970.

7,12-Dimethylbenz(a)anthracene (1, 2.5 or 5 mg p.o.) was administered to female rats which had been maintained on a semisynthetic diet containing 20% corn oil, and to a comparison group which had received a semisynthetic low-fat diet to determine whether dietary fat has an effect on the carcinogenic efficacy of the test compound. The tumor yield (% incidence) was 7%, 57% and 93% in animals given 1, 2.5 or 5 mg of 7,12-dimethylbenz(a)anthracene, resp., with the 20% corn oil diet; with the 0.5% corn oil diet, the tumor yield was 4%, 33% and 70%, resp., for 1, 2.5 or 5 mg of carcinogen administered. The type of diet fed after administration of 7,12-dimethylbenz(a)anthracene had a greater influence on mammary tumor incidence than did the type of diet fed before the carcinogen was given, indicating that the promotional stage of

mammary carcinogenesis is the primary target of the low-fat effect.

- 0063 EFFECT OF 7,12-DIMETHYLBENZ(a)ANTHRACENE ON NON-NEOPLASTIC AND NEOPLASTIC RODENT CELLS IN CULTURE. (E.) Evans, V. J. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), F. M. Price, H. A. Kerr and H. M. De Oca. *J Nat'l Cancer Inst* 45(3): 429-441, 1970.

Neoplastic and non-neoplastic paired cell lines of mouse, rat and hamster were treated with 7,12-dimethylbenz(a)-anthracene *in vitro* to gauge their resistance or susceptibility to the toxic effects of the chemical. Sensitivity to the carcinogen (inhibition of growth) consistently correlated with the non-malignant state, except for freshly explanted mouse embryo tissue. However, long-term cultures of mouse embryo in fetal calf serum acquired sensitivity to the chemical. Data from such cells, usually obtained only after prolonged latent periods in appropriate hosts, are mandatory to confirm whether these cells can produce tumors. The observed correlation between resistance to 7,12-dimethylbenz(a)anthracene toxicity and malignancy in some long-term and freshly explanted cell systems may indicate that the *in vitro* tissue carried over a protective factor from the *in vivo* state.

- 0064 INTERACTION BETWEEN ESTROGENIC AND CARCINOGENIC SUBSTANCES IN THE RAT MAMMARY GLAND. (E.) Sander, S. (U. Hosp., Oslo, Norway) and O. Torgersen. *Acta Path Microbiol Scand* 78(3):289-294, 1970.

Interaction between estrogenic (estradiol-17 β) and carcinogenic (7,12-dimethylbenzanthracene, DMBA) substances was evaluated in the rat mammary gland by determining tumor incidence after DMBA injection (3 mg, i.v.) during the metestrous or proestrous/estrous phases and by measuring ³H-DMBA uptake after estradiol-17 β priming. Tumors were induced in both the metestrous phase (20 adenocarcinomas) and in the proestrous/estrous phase (16 adenocarcinomas), and the 10 animals that did not develop tumors had been in different phases of the estrous cycle when DMBA was applied. Ovariectomy performed when the tumors reached 10 mm diameter produced histological signs of regression in 25 tumors, 8 remained hormone-unresponsive and continued to grow, and 3 were unaffected. Estradiol-17 β -primed animals and controls had the same DMBA uptake, indicating that no competition for intracellular binding sites existed. The development of both hormone-responsive and hormone-unresponsive tumors in the same animal suggests an importance of local factors in hormone-sensitivity in breast cancers.

- 0065 INHIBITION BY GERM-FREE STATUS OF DEVELOPMENT OF LIVER AND LUNG TUMORS IN MICE EXPOSED NEONATALLY TO 7,12-DIMETHYLBENZ(a)ANTHRACENE: IMPLICATIONS IN RELATION TO TESTS FOR CARCINOGENICITY. (E.) Roe, F. J. C. (Roy. Cancer Hosp., London, England) and G. A. Grant. *Int J Cancer* 6(1):133-144, 1970.

The carcinogen 7,12-dimethylbenz(a)anthracene was injected into germ-free male mice shortly after birth to determine if the germ-free condition protected them against tumor formation. Germ-free status significantly protected mice from the early development of liver-cell tumors and from the early development of adenomas of the lung in response to the same treatment, and may have protected 7,12-dimethylbenz(a)anthracene-treated female mice from the development of malignant lymphoma, mammary, ovarian and uterine tumors. Age in excess of 80 weeks counteracted the protective effect of germ-free status. Germ-free status had no consistent effect on the incidence of sarcomas at the site of neonatal injection of 7,12-dimethylbenz(a)anthracene. The fact that a factor as non-specific as the difference between normal microbiological status and germ-free status may have such a profound effect on the age-standardized risk of development of lung and liver tumors in mice, suggests that the term "carcinogen" should not be applied to an agent if the only evidence of relevant activity is that it increases the risk of development of either or both these types of tumors in mice. Germ-free status may influence the response to 7,12-dimethylbenz(a)anthracene by an effect on the host organism's immunological status; the immunological defenses of an animal with no stresses upon its immune system by microbial flora in the environment may be better able to resist cell deviants resulting from exposure to 7,12-dimethylbenz(a)anthracene than those of an animal exposed to the usual complement of microbial flora.

- 0066 STUDIES ON THE METABOLISM OF 7-METHYLBENZ[a]ANTHRACENE AND 7,12-DIMETHYLBENZ[a]ANTHRACENE AND ITS HYDROXYMETHYL DERIVATIVES IN RAT LIVER AND ADRENAL HOMOGENATES. (E.) Sims, P. (Roy. Cancer Hosp., London, England). *Biochem Pharmacol* 19(7):2261-2275, 1970.

The metabolism of tritiated 7,12-dimethylbenz(a)-anthracene, 7-methylbenz(a)anthracene and their hydroxymethyl derivatives was studied with liver homogenates from normal and 3-methylcholanthrene-treated rats. Liver homogenates from rats pretreated with 3-methylcholanthrene converted 7-hydroxymethyl-12-methyl and 12-hydroxymethyl-7-methylbenz(a)anthracene into phenols and dihydrodiols; some hydroxylation of the methyl groups also occurred. Qualitative and quantitative studies of the metabolism of 7,12-dimethylbenz(a)anthracene, 7-methylbenz(a)anthracene and the above hydroxymethyl derivatives showed that with liver homogenates from normal rats products were formed that arise either by ring-hydroxylation or by hydroxylation of the methyl groups, whereas with homogenates of the adrenals from the same animals ring-hydroxylation but little or no hydroxylation of the methyl groups occurred. Adrenal homogenates were more efficient than liver homogenates in effecting the ring hydroxylations of these compounds. Large increases in the amounts of metabolites formed from the above substrates occurred when homogenates of the livers of rats that had been pretreated with 3-methylcholanthrene were used: no such increases were found when homogenates of the adrenals of these animals were used.

0067 INTERACTIONS OF THE K-REGION EPOXIDES OF PHENANTHRENE AND DIBENZ[a,h]ANTHRACENE WITH NUCLEIC ACIDS AND HISTONE. (E.) Grover, P. L. (Roy. Cancer Hosp., London, England) and P. Sims. *Biochem Pharmacol* 19(7):2251-2259, 1970.

The reactivities of phenanthrene-9,10-oxide and dibenz(a,h)anthracene-5,6-oxide with 4-(p-nitrobenzyl)pyridine, RNA, DNA and histone were compared with the parent compounds phenanthrene and dibenz(a,h)anthracene, as well as with alkylating agents such as ethyl methanesulfonate and ethyl methanesulfonate. In neutral solution at 37°C, the K-region epoxides of phenanthrene and dibenz(a,h)anthracene were more reactive towards 4-(p-nitrobenzyl)pyridine than the alkylating agents or their parent hydrocarbons; the epoxides also reacted with DNA, RNA and histone, but the parent hydrocarbons and respective K-region dihydrodiols did not. Addition of washed rat liver microsomes to reaction mixtures containing DNA and either phenanthrene-9,10-oxide or dibenz(a,h)anthracene-5,6-oxide decreased the level of interaction of phenanthrene-9,10-oxide with DNA but not that of dibenz(a,h)anthracene-5,6-oxide. Fluorimetric estimations showed that over a 24-hr period only 1-5% of each epoxide underwent rearrangement to the corresponding phenol and over 90% of the epoxides remained unchanged. The relative stability of a carcinogenic intermediate may be important if the intermediate formed by microsomal metabolism has to enter the nucleus to react with DNA.

0068 THE EFFECT OF ACUTE X-IRRADIATION ON THE CELL PROLIFERATION KINETICS OF INDUCED CARCINOMAS AND THEIR NORMAL COUNTERPART. (E.) Brown, J. M. (Stanford U. Sch. Med., Calif.). *Radiat Res* 33(3):627-653, 1970.

The effect of acute doses of X-irradiation (500 and 1000 rads) on the generation cycle of proliferating cells was compared in chemically-induced (by painting with 7,12-dimethylbenz(a)anthracene squamous cell carcinomas and normal tissue in the cheek pouch of the Syrian hamster using *in vivo* ³H-thymidine labeling (1 µC/g body wt, i.p.) and standard autoradiographic methods. In the unirradiated tumor cells, the mean cell cycle was 11.7 hr, the mean growth fraction (fraction of carcinoma cells proliferating at any one time) was 31%, and the cell loss factor (number of cells lost from the tumor volume) was 0.75. In normal basal cells, the labeled mitosis technique for determining the cell cycle time proved ineffective, and the 3 other methods used (continuous labeling, rate of differentiation of basal cells, and calculation from the equation $T_c = T_s / LI$) gave a range of 130 to 152 hr. Irradiation of the tumor cells with 500 rads did not affect the parameters of the cell cycle although the G₂ period was slightly lengthened (1.8 to 2.6 hr) and the S phase showed greater variation among individual tumors; irradiation with 1000 rads produced a lengthening of the G₁ period (1.8 to 4.5 hr) along with the increased spread of the S phase. Irradiation of normal epithelium with the same doses shortened the cell cycle of the basal cells by 20 to 35% for approximately 3 weeks following irradiation and the effect was due almost entirely to a shortened G₁ period.

0069 STUDIES ON THE KINETICS OF THE INHIBITION OF BENZO(a)PYRENE BREAKDOWN. (Ger.) Tomingas, R. (Med. Inst. U. Düsseldorf, Germany), W. Dehnen and S. Jackson. *Z Krebsforsch* 74(3):279-282, 1970.

The inhibition kinetics of aryl-hydroxylase-mediated benzo(a)pyrene hydroxylation were studied with anthracene, benzo(a)anthracene, benzo(e)pyrene, pyrene, phenanthrene and 3-methylcholanthrene *in vitro*. All these compounds (usually concomitant with benzo(a)pyrene in air dust) inhibited the breakdown of benzo(a)pyrene. Lineweaver-Burk plots revealed a competitive type of inhibition. Application of these findings on the physiological level will be of doubtful value until the mechanism of release of these polycyclic aromatic compounds from the inhaled dust particles is clarified.

0070 INHIBITION OF THE CARCINOGENIC ACTION OF BENZO(a)PYRENE BY FLAVONES. (E.)

Wattenberg, L. W. (U. Minnesota Med. Sch., Minneapolis) and J. L. Leong. *Cancer Res* 30(7):1922-1925, 1970.

Female mice were fed flavone inducers of increased benzo(a)pyrene hydroxylase activity to assess the effect of this treatment on pulmonary adenoma development. The mice were fed inducers for 16 days at 7 weeks and at 11 weeks and each course of treatment was followed by 2 p.o. administrations of 3 mg of benzo(a)pyrene. Three flavones were used: β-naphthoflavone, a highly potent inducer; quercetin pentamethyl ether, intermediate in inducing potency; and rutin, a weak inducer. Administration of β-naphthoflavone (3 mg/g diet) resulted in almost total inhibition of pulmonary adenoma formation; with quercetin pentamethyl ether (5 mg/g diet) approximately 50% inhibition occurred, and with rutin (5 mg/g diet) there was no inhibition. In a second investigation the effect of inducing increased benzo(a)pyrene hydroxylase activity in the skin of mice on epidermal neoplasia initiated by benzo(a)pyrene was studied. More than 50% tumor formation inhibition was achieved by topical application of β-naphthoflavone.

0071 INFLUENCE OF METHYLCHOLANTHRENE AND PHENOBARBITAL TREATMENT ON LIVER CHROMATIN TEMPLATE ACTIVITY IN THE RAT. (E.) Piper, W. N. (Sch. Pharm. Pharm. Sci., Purdue U., Lafayette, Ind.), D. E. Blake and W. F. Bousquet. *Res Commun Chem Path Pharmacol* 1(5):591-606, 1970.

Male rats were given i.p. injections of phenobarbital (100 mg/kg) or 3-methylcholanthrene (30 mg/kg) to investigate the effects of these compounds on liver chromatin template activity. 3-Methylcholanthrene increased hepatic chromatin template activity 100% above control values by 12 hr after administration, whereas phenobarbital or phenobarbital plus 3-methylcholanthrene increased template activity only 10-20%. Treatment of chromatin with acid, to remove basic protein, abolished these differences in template activity; thus, basic protein (histone) appears to be responsible for the difference in chromatin template activity. Similar DNA/protein ratios in chromatin from control and drug-treated

animals indicated that the observed differences in template activity were not due to an alteration in the protein content of chromatin. Adrenalectomy abolished the increase in chromatin template activity produced by phenobarbital treatment, but had no effect on that produced by 3-methylcholanthrene, suggesting that the mechanism by which these agents act to stimulate protein synthesis is different. The ratio of 3-methylcholanthrene bound to chromatin compared to that bound to homogenate protein was considerably larger than that for phenobarbital. Isotope studies established that neither drug caused an alteration in turnover of chromatin-histone protein at 1 or 6 hr after administration, indicating that altered turnover and acetylation of chromatin protein are not responsible for the differences in template activity.

- 0072 QUANTITATIVE DETECTION OF CYTOTOXIC ANTIBODIES AGAINST TUMOR-SPECIFIC ANTIGENS OF MURINE SARCOMAS INDUCED BY 3-METHYLCHOLANTHRENE. (E.) Bloom, E. T. (Dept. Med. Microbiol., Immunol., U. California, Los Angeles). *J Nat Cancer Inst* 45(3): 443-453, 1970.

A murine sarcoma indigenous to the C57BL/10 strain of isogenic mice, and induced by 3-methylcholanthrene, was studied to investigate the antibody response to the tumor-specific antigens associated with it. A new microtechnique was used to detect and assay cytotoxic antibody against tumor-specific antigen, and only microliter quantities of serum were necessary for multiple titrations. The reproducibility of the method was demonstrated at a high level of significance; and the cytotoxic effect depended on the addition of exogenous complement. Furthermore, the detectable antibody titers were specific for the sensitizing sarcoma; antiserum activity resided in the IgG and IgM immunoglobulin fractions. The cytotoxic effect, induced by antigenic stimulation, was boosted with further challenge. This evidence appears to support the conclusion that the cytotoxic effect *in vitro* resulted from a true tumor-specific antibody response.

- 0073 CARCINOGEN-INDUCED TUMORS IN PRIMITIVE PRIMATES. (E.) Adamson, R. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), R. W. Cooper and R. W. O'Gara. *J Nat Cancer Inst* 45(3):555-559, 1970.

The carcinogen 3-methylcholanthrene was injected s.c. into 6 tree shrews (*Tupaia glis*) in 10 mg doses to test the susceptibility of prosimians to malignant tumor induction by this agent. Three died within 4 months and the 3 survivors developed fibrosarcomas within 14-16 months. Benzo[a]pyrene was injected s.c. into another species of prosimian primate, *Galago crassicaudatus*. Twelve galagos have survived for more than 6 months after injection of the carcinogen, and 1 developed a tumor at the injection site. Histologically the tumor was a fibrosarcoma, and metastatic tumor was found in the lung. The induction of malignant tumors in higher primates by polycyclic hydrocarbons has proved difficult. It is concluded that some prosimians are more similar

to rodents than to the higher primates in their reaction to carcinogenic polycyclic hydrocarbons.

- 0074 DIURNAL VARIATION IN SUSCEPTIBILITY OF MOUSE SKIN TO THE TUMORIGENIC ACTION OF METHYLCHOLANTHRENE. (E.) Iverson, U. (U. Hosp. Oslo, Norway), O. H. Iversen, H. Hennings and R. Bjerknes. *J Nat Cancer Inst* 45(2):269-276, 1970.

Hairless mice were given a single application of 3-methylcholanthrene (125 µg in benzene) at 0800 and 2400 hr and observed weekly for 20 months to determine if a diurnal variation exists in skin susceptibility to this carcinogen. While no difference was found in tumor induction time or the number of tumor-bearing mice, the group treated at 2400 developed significantly more skin tumors. At 2400, the mitotic rate increased 3-4 times and the number of cells in DNA synthesis increased 40-50% over values found at 0800. The 35% difference in papilloma yield correlates somewhat better with the corresponding difference in number of DNA-synthesizing cells than with the more pronounced variation in mitotic rate. Binding studies with ³H-methylcholanthrene showed 15% higher DNA binding, 10% lower RNA binding and no difference in protein binding after 12 hr with application at 2400 compared to 0800 application.

- 0075 *IN VIVO* ELECTROMETRIC STUDY OF CARCINOGENIC HYDROCARBON INTERACTION WITH MOUSE EPIDERMIS (E.) Smolen, V. F. (Sch. Pharm., Sci., Purdue U., Lafayette, Ind.), D. E. Snyder and R. J. Erb. *J Pharm Sci* 59(8):1093-1098, 1970.

The interaction of the 3-methylcholanthrene and benzene with the epidermis of hairless mice was studied by the use of a bioelectrometric technique involving measurement of electrical potentials developed at the boundary of the affected tissue and a buffer solution which may or may not contain the substances under examination. Use of a bioelectrometric technique permitted experimental results to be obtained entirely *in vivo* without injury to the mice. The results obtained are analogous to titration curves of amphoteric macromolecules. Inspection of the curves and their temporal variations following the topical application of the hydrocarbons revealed the induction of significant changes in the density of ionogenic groups affixed to the epidermal colloids. 3-Methylcholanthrene was observed to induce consistently a reduction (overall average reduction of 23%) of net cationic fixed-charge density attributable to the loss or discharge of basic nitrogenous groups titratable above, at least pH 7.4. Although the mechanism whereby 3-methylcholanthrene reduces the fixed cationic charge density is obscure, it is speculated that the reduction of the charge may result from formation of covalent bonds or from an allosteric mechanism.

- 0076 EFFECTS OF VARIOUS ONCOGENIC AGENTS ON TUMOR-PRODUCING CAPABILITIES OF SERIES D BALB/c MAMMARY NODULE OUTGROWTH LINES. (E.) Medina, D. (Baylor Coll. Med., Houston, Tex.) and K. B. DeOme. *J Nat Cancer Inst* 45(2):353-363, 1970.

The effects of various oncogenic agents (mammary tumor virus, nodule-inducing virus, 3-methylcholanthrene and pituitary isografts) on the tumor-producing capabilities of nodule outgrowth lines D1, D2, D3, D4, D5, D7 and D8 was investigated in BALB/c mice. Fifty percent of the transplants produced tumors in 308, 182, 161, 238, 364 and 168 days in D1, D2, D2a, D3, D4 and D8 lines, resp. Mammary tumor virus infection increased the incidence of mammary tumors and decreased the mean latent period as compared to the same outgrowths transplanted into mammary tumor virus-free BALB/c mice, except for D5. Nodule-inducing virus showed some effect on the tumor potential of line D3 but not of line D3. 3-Methylcholanthrene increased the tumor potential of outgrowth lines D2 and D3 (45% and 60%, resp.); pituitary isografts increased the tumor potential of line D2 (12%). The D series of nodule outgrowth lines appears to show a wide variety of responsiveness to various viral and chemical oncogenic agents and responses cannot be predicted from their background tumor potential.

0077 TRANSFER OF TUMOR-SPECIFIC IMMUNITY WITH RNA: DEMONSTRATION BY IMMUNE CYTOLYSIS OF TUMOR CELLS *IN VITRO*. (E.) Ramming, K. P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and Y. H. Pilch. *J Nat Cancer Inst* 45(3):543-553, 1970.

Guinea pigs were immunized with a 3-methylcholanthrene-induced strain-2 liposarcoma, and RNA-rich extracts were prepared from their spleens to investigate the mediation of tumor-specific transplantation immunity by such RNA-rich extracts. Normal, nonimmune, strain-2 lymphoid cells incubated with these RNA preparations caused specific immune cytolysis of 3-methylcholanthrene-induced liposarcoma cells *in vitro*. Treatment of the active RNA preparations with ribonuclease resulted in their complete inactivation. RNA from the spleens of guinea pigs not exposed to the tumor was ineffective, and incubation of lymphoid cells with extracts of 3-methylcholanthrene-induced liposarcoma rich in solubilized tumor-specific antigens did not reproduce the immune cytolysis caused by the active RNA preparations. Spleen cells incubated in RNA extracted from strain-2 guinea pigs immunized with 3-methylcholanthrene-induced liposarcoma did not cause significant immune cytolysis when applied to monolayers of MCA-25, a strain-2 sarcoma whose tumor-specific transplantation antigens do not cross-react with 3-methylcholanthrene-induced liposarcoma.

0078 EXPERIMENTAL TUMOR METASTASES AND BLOOD COAGULABILITY. (E.) Hagmar, B. (Dept. Path., U. Goteborg, Sweden). *Acta Path Microbiol Scand* 78(suppl. 211):1-38, 1970.

The relation of blood coagulability to the growth and spread of metastases from transplanted tail tumors in mice was studied using heparin, phenprocoumon, ε-aminocaproic acid (EACA), protamine, and chondroitin sulfate in 3 syngeneic tumor-host systems (3-methylcholanthrene-induced sarcoma, MCG1-SS, and its solid ascites form, MCG1-AS, in CBA mice, and a spontaneous melanoma B16 in C57BL/6J mice). Heparin (100 IU,

s.c.) given 3 times daily from days 7-12 after tumor transplantation increased the average and total volumes of MCG1-SS and MCG1-AS pulmonary metastases and increased the take frequency and total volume of melanoma B16 metastases. Phenprocoumon (0.02 mg, i.p.) reduced the number and total volume of MCG1-SS pulmonary metastases but did not affect MCG1-AS or melanoma B16 metastases. EACA (30% powdered diet) reduced the average and total volumes of MCG1-SS pulmonary metastases, the number and total volume of MCG1-AS metastases, and the average volume of melanoma B16 pulmonary metastases. Treatment with heparin, phenprocoumon, and EACA 6 days after the tumors had been amputated did not significantly affect the growth of metastases on MCG1-SS or MCG1-AS. When treatment was started on days 2 or 3 after tumor transplantation, and the tumors were amputated on day 5, heparin-treated animals had a higher incidence of pulmonary metastases than the other groups, while phenprocoumon and EACA did not alter the time for metastatic spread. When heparin was used on intravenously induced tumors, the number of pulmonary MCG1-SS metastases increased while extrapulmonary metastases were unaltered; the number of extrapulmonary melanoma B16 metastases increased, suggesting that the heparin effect may be a redistribution of tumors. Phenprocoumon increased the extrapulmonary takes and pulmonary B16 metastases, but did not affect pulmonary MCG1-SS metastases. Chondroitin sulfate altered cellular volumes and metastases in a similar manner to heparin, while protamine, a polycation, had rather reverse effects.

0079 INFLUENCE OF MULTIPLE INJECTIONS OF NORMAL SYNGENEIC CELLS ON TUMOR INDUCTION IN MICE. (E.) Reiner, J. (Sloan Kettering Inst. Cancer Res., New York, N.Y.). *Cancer Res* 30(8):2087-2088, 1970.

The effect of injections of normal and X-irradiated syngeneic cells on the oncogenic response to methylcholanthrene in mice was investigated. A series of 50 injections of 0.1 ml of a 10% suspension of normal syngeneic or X-irradiated cells into the right flank at 3- or 4-day intervals did not produce palpable nodules or any noticeable changes. Methylcholanthrene (10 µg i.m.) administered 1 week after the 50th injection of liver cells caused tumor development after 10 weeks. At 52 weeks, 72% of the control mice had developed sarcomas and died, while tumor incidence in mice treated with normal syngeneic liver cells and X-irradiated cells was 53% and 46%, resp. The ectopic injection of normal liver cells presumably activated mechanisms which normally remove necrobiotic cells during renewal and repair of normal tissue, and it may be these same mechanisms can also act to remove neoplastically transformed cells as they arise.

0080 EFFECT OF CUMULATIVE DOSE AND DOSE RATE ON DIMETHYLNITROSAMINE ONCOGENESIS IN RF MICE. (E.) Clapp, N. K. (Oak Ridge Natl. Lab., Tenn.) and R. E. Toya, Sr. *J Nat Cancer Inst* 45(3):495-498, 1970.

The carcinogenic effect of dimethylnitrosamine was assessed in male RF mice given dimethylnitrosamine in drinking water for varying periods, total doses

ranging from 87-243 mg/kg. The incidence of lung adenomas in all treated groups increased over controls by a factor of 2 and reached nearly 100%. The incidence of liver hemangiosarcomas increased in higher dose groups and reached a maximum of 96%, but the incidence of hepatocellular tumors were not affected. In 2 groups receiving the same total dose, hemangiosarcomas appeared only in the group treated at the highest dose rate, which suggested that damage was repaired at the lower dose rate. The fact that lung-tumor incidence with dimethylnitrosamine was high may indicate that metabolism of this chemical into a proximate carcinogen probably occurred in the lung parenchyma as well as in the liver; the absence of tumors in the kidney of the RF mouse suggested that the necessary enzyme system was not present. Because liver hemangiosarcomas and hepatocellular tumors, 2 distinctly different cell types, were induced by dimethylnitrosamine and diethylnitrosamine, resp., the cell type in which metabolism occurs may be specific within an organ.

0081 LIVER MORPHOLOGY FOLLOWING A SINGLE INJECTION OF DIMETHYLNITROSAMINE, 7,12-DIMETHYLBENZ(a)ANTHRACENE, AND URETHAN TO ADULT AND SUCKLING B6AF₁ MICE. (E.) Warwick, G. P. (Roy. Cancer Hosp., London, England) and I. N. Chernozemski. *Chem Biol Interact* 2(1):29-39, 1970.

Adult and 1-wk-old mice received single s.c. injections of dimethylnitrosamine, 7,12-dimethylbenz(a)-anthracene, or urethan with the aim of investigating the effects of these compounds on liver morphology; the injections produced hepatomas in suckling mice but not in adults. Dimethylnitrosamine was highly toxic at a dose of 15 µg/g wt. After treatment with 10 µg/g, less than 10% of the animals died and the rest showed marked congestion and severe centrilobular necrosis accompanied by ascites. The damage was more pronounced in livers of suckling mice where blood-forming cells also disappeared. Slow recovery began during the 2nd wk; undamaged parenchymal cells hypertrophied and some underwent cell division. 7,12-Dimethylbenz(a)anthracene at a dose of 20 mg/g caused mild congestion and parenchymal cell infiltration localized in the middle and outer zones of the lobules. Both effects were transitory and less apparent in suckling mice. Urethan affected small vessels but almost no damage was observed in the parenchyma of the suckling mice (dose 1.2 mg/g). However, blood stem cells exhibited toxic injuries and apparently completely disappeared for about one week. In adults urethan at a dose of 1 mg/g provoked diffuse transitory hydropic vacuolization of parenchymal cell cytoplasm, vessel wall injury, and slight perivascular edema. An inverse correlation was found generally between the hepatocarcinogenicity of the compounds and their liver toxicity.

0082 THE EFFECT OF S-ADENOSYLMETHIONINE ON THE METHYLATION OF LIVER RNA BY DIMETHYLNITROSAMINE *IN VIVO*. (Ger.) Krüger, F. W. (German Cancer Res. Inst., Heidelberg, Germany), U. Rucker and M. Wiessler. *Z Krebsforsch* 74(2):162-170, 1970.

The relation between S-adenosylmethionine and dimethylnitrosamine methylation of guanine in liver RNA was studied by i.v. administration of labeled methionine to control rats and additional high dosage administrations of dimethylnitrosamine (40 mg/kg) to the experimental group; the animals were sacrificed 6 hr after treatment. Concomitant S-adenosylmethionine and dimethylnitrosamine studies were performed on mice. Physiological formation of 7-methylguanine was not competitively inhibited by high doses of dimethylnitrosamine. High doses of S-adenosylmethionine (within its toxicity limits) enhanced formation of 7-methylguanine by labeled (C¹⁴) dimethylnitrosamine methylation. Incorporation of dimethylnitrosamine label into RNA bases was promoted by S-adenosylmethionine in all experimental groups.

0083 A STUDY OF NITROSAMINES AND S-CARBOXYL DERIVATIVES OF CYSTEINE AS LUNG CARCINOGENS IN ADULT SWR MICE. (E.) Mirvish, S. S. (U. Nebraska Coll. Med., Omaha) and L. Kaufman. *Int J Cancer* 6(1):69-73, 1970.

Dimethylnitrosamine, diethylnitrosamine, nitrosopiperidine, di-n-butyl nitrosamine, N-acetyl-S-carbethoxycysteine, S-carbobenzoyloxycysteine and S-carbamylcysteine were injected i.p. into mice to determine their carcinogenic effects on the lung compared to those of urethan. Dimethylnitrosamine (10 mg/kg) and diethylnitrosamine (100 mg/kg) were almost as active as urethan (1 mg/kg). Although the molar dose for dimethylnitrosamine was one-seventh of that for diethylnitrosamine, the former produced the greater effect (8 tumors/mouse vs 5 tumors/mouse). In contrast, for liver carcinogenesis in the rat, diethylnitrosamine is known to be at least as potent as dimethylnitrosamine. Nitrosopiperidine and di-n-butyl nitrosamine showed borderline activities. Similar tests were performed on the urethan metabolite N-acetyl-S-carbethoxycysteine and the related compounds S-carbamylcysteine and S-carbobenzoyloxycysteine, to determine if a cysteine derivative of urethan is responsible for the carcinogenic activity of urethan; no significant tumor induction was observed with these compounds.

0084 CIRCADIAN CHANGES IN THE PERMEABILITY OF NUCLEAR MEMBRANES OF RAT LIVER CELLS FOLLOWING DIETHYLNITROSAMINE ADMINISTRATION. (Ger.) Kittlick, P. D. (Path. Inst. Friedrich Schiller U., Jena, Germany). *Exp Path* 4(2-3):204-206, 1970.

Circadian changes in liver cell nuclear permeability were studied in male Wistar rats treated with diethylnitrosamine for 10 weeks (total 60 mg in drinking water), with daily light exposure from 6 A.M. to 7 P.M.. The animals were sacrificed during the first half of December and experimental data were compared to control data obtained 12 months previously. Pyrophosphate transport was taken as a measure of nuclear permeability and was determined from NAD measurements before and after incubation from the reaction NAD + pyrophosphate = nicotinamide mononucleotide + ATP. Precancerous liver cell nuclei revealed 2 peaks of maximum membrane permeability per 24 hr while control

data showed a single peak in 24 hr. Such alterations were attributed to an enhanced breakdown of certain membrane permeability regulating factors (hormone metabolism) occurring in the preneoplastic cell.

0085 DIETHYLNITROSAMINE CARCINOGENESIS IN RAT LIVER: SORBITOL DEHYDROGENASE HISTOCHEMISTRY. (Ger.) Stiller, D. (Path Inst. Friedrich Schiller U., Jena, Germany). *Exp Path* 4(2-3):207-209, 1970.

decrease in sorbitol dehydrogenase (SDH) activity in rat liver central lobules (diffuse cytoplasmic reaction) was noticed during the first 4 wk of daily diethylnitrosamine administration (0.75 mg in drinking water). A distinct drop in formazan formation in the central lobules occurred on the 10th wk of treatment while total liver SDH activity was still considerable. Clear SDH defective areas appeared between the 12th and 14th wk of treatment (73.5 mg diethylnitrosamine) from which microcarcinomas and carcinomas were generated. Such enzyme defects appeared to be irreversible and were considered as part of the preneoplastic stage in diethylnitrosamine hepatocarcinogenesis.

0086 TUMORIGENICITY OF CYCLIC NITROSAMINES IN SYRIAN GOLDEN HAMSTERS. (E.) Lijinsky, W. (U. Nebraska Med. Ctr., Omaha), A. Ferrero, R. Montesano and C. E. M. Wenyon. *Z Krebsforsch* 74(2):185-189, 1970.

Syrian golden hamsters were given nitrosoazetidine and nitrosoheptamethyleneimine via drinking water (200 mg/l and 50 or 200 mg/l, resp.) to test the carcinogenic effects of these compounds. Although nitrosoazetidine appeared noncarcinogenic in this species, nitrosoheptamethyleneimine was strongly carcinogenic, producing tumors in 21/30 of the animals mainly in the forestomach, esophagus, larynx, pharynx, nasal cavity and trachea. Most of the tumors in the esophagus, larynx, pharynx and nasal cavity were malignant. While nitrosoheptamethyleneimine produced bronchogenic carcinomas in the lungs of rats, it did not induce bronchogenic carcinomas in hamsters.

0087 CARCINOGENICITY OF NITROSTHIOMORPHOLINE AND 1-NITROSOPIPERAZINE IN RATS. (E.) Garcia, H. (U. Nebraska Coll. Med., Omaha), L. Keefer, W. Lijinsky and C. E. M. Wenyon. *Z Krebsforsch* 74(2):179-184, 1970.

The carcinogenic effects of long term feeding to rats of nitrosthioamorpholine and nitrosopiperazine in drinking water (50 mg/l and 200 mg/l) were investigated. Twenty-two of 48 animals treated with nitrosthioamorpholine (760 or 190 mg in 38 weeks) developed tumors of the esophagus and tongue. Nitrosopiperazine treatment (1,200 or 300 mg in 60 weeks) resulted in tumor induction in a wide range of organs and tissues in 22 out of 33 animals; 16 out of 70 of the untreated control rats also developed tumors.

0088 EFFECTS OF DOSE AND SCHEDULE OF METHYLNITROSOUREA ON INCIDENCE OF MALIGNANT LYMPHOMA IN ADULT FEMALE MICE. (E.) Joshi, V. V. (Cancer Res. Lab., U. Western Ontario, London, Canada) and J. V. Frei. *J Nat Cancer Inst* 45(2):335-339, 1970.

Female inbred mice were given single and fractionated doses of methylnitrosourea at daily or weekly intervals to determine the early mortality, incidence and latency of malignant lymphomas induced by this compound. In the single dose group (25-100 mg/kg), early mortality was first seen at 75 mg/kg, the highest incidence of malignant lymphoma was 72%, and the shortest latent period was 144 days. In the fractionated dose group, the pattern of fractionation, (the interval between the fractions) influenced all 3 parameters. In the daily fractionated group, early mortality first appeared at the total dose of 200 mg/kg, the highest incidence of malignant lymphoma was 93%, and the shortest latent period was 139 days. In the weekly fractionated group, early mortality first appeared at the total dose of 250 mg/kg, the highest incidence of malignant lymphoma was 93%, and the shortest latent period was 87 days. Thus reduction of early mortality, enhancement of incidence, and shortening of latent period of malignant lymphoma were the main effects of fractionated doses of methylnitrosourea.

0089 OCCURRENCE OF DESMOSTEROL IN TUMORS OF THE NERVOUS SYSTEM INDUCED IN THE RAT BY NITROSOUREA DERIVATIVES. (E.) Weiss, J. F. (New York U. Med. Ctr., New York), E. G. Paoletti, P. Paoletti, D. Schiffer and A. Fabiani. *Cancer Res* 30(8):2107-2109, 1970.

Desmosterol accumulation in considerable amounts was observed in experimental tumors of the nervous system induced in Long-Evans rats either by i.v. administration of methylnitrosourea or by transplacental induction with ethylnitrosourea. Injections of 25 mg/kg of methylnitrosourea once a month for 8 months in the tail vein of rats induced oligodendrogliomas, isomorphous gliomas, polymorphous gliomas and a few neurinomas; 6.4-16.3% of the total sterols in the oligodendrogliomas was found to be desmosterol. In the series of neoplasms induced transplacentally with ethylnitrosourea (10 mg/kg on the 17th day of pregnancy), a large number of neurinomas of the Gasserian ganglion and spinal neurinomas and a few oligodendrogliomas and 1 polymorphous glioma developed. As in the methylnitrosourea series, the oligodendrogliomas contained 10-14% desmosterol and the neurinomas contained up to 18.5% desmosterol. The presence of this sterol is a fairly constant finding in induced animal neurinomas which are very rapidly proliferating tissues; desmosterol is not found in human neurinomas, which are generally slow growing and rarely malignant, indicating that the presence of desmosterol may be related to the growth velocity of the tumors.

0090 INDUCTION OF NEUROGENIC MALIGNANCIES BY ONE SINGLE DOSE OF ETHYLNITROSOUREA (ENU) GIVEN TO NEWBORN AND JUVENILE BD IX-STRAIN RATS. (Ger.)

Druckrey, H. (Max Planck Inst. Immunobiol., Freiburg, Germany), B. Schagen and S. Ivankovic. *Z Krebsforsch* 74(2):141-161, 1970.

Malignant and multiple tumors of the nervous system were observed in 242 rats at age 1, 10 and 30 days following a single dose of ethylnitrosourea ranging from 5-80 mg/kg. Brain tumors, ependymomas, oligodendrogliomas, astrocytomas, and mixed gliomas were observed in 144 animals, malignant tumors of the spinal cord in 70, of the cranial nerves in 89, and of the parasympathetic nervous system in 140 rats. Nine rats died from tumors of the heart, 7 of which were classified as malignant neurinomas. In all 3 age groups clear dose-response relationships were obtained. The sensitivity of the nervous system to the carcinogenic action of ethylnitrosourea, judged by the tumor yield and the length of the latent period in the respective dosage groups, decreased to about a tenth within the first month after birth, whereas the incidence of nephroblastomas increased with the age at treatment and the dose.

0091 LEUKEMOGENESIS OF N-NITROSOBUTYLUREA IN THE RAT: I. EFFECT OF VARIOUS CONCENTRATIONS IN THE DRINKING WATER TO FEMALE DONRYU RATS. (E.) Odashima, S. (Sasaki Inst. Tokyo, Japan). *Gann* 61(3):245-253, 1970.

Erythroblastic or stem-cell type leukemias were induced in 3 groups of female rats by the administration in drinking water of N-nitrosobutylurea (0.01, 0.02, or 0.04% soln); a higher percentage (76 and 100%, resp.) of leukemias were induced in the groups receiving 0.02 and 0.04% soln. Lesions and tumors induced in other organs included: hyperkeratosis of the forestomach, papillomas and basal cell carcinomas of the forestomach and esophagus, ear duct carcinomas, mammary adenocarcinoma, reticulum cell sarcoma, and adenomatous polyp of the small intestine. More extrahematopoietic tumors were found in the animals that received the lowest daily dose of N-nitrosobutylurea. A higher frequency of leukemia was produced earlier in the experimental period (19-23 wk) by 0.04% of N-nitrosobutylurea, and more extrahematopoietic tumors were produced later (34-45 wk) by the 0.01% concentration.

0092 LEUKEMOGENIC AND MAMMARY TUMORIGENIC EFFECTS OF N-NITROSOBUTYLUREA IN MICE AND RATS. (E.) Yokoro, K. (Res. Inst. Nucl. Med. Biol., Hiroshima U., Japan), N. Imamura, S. Takizawa, H. Nishihara and E. Nishihara. *Gann* 61(3):287-289, 1970.

The leukemogenicity of N-nitrosobutylurea was investigated in mice as well as in rats to learn more about the effect of species and strain differences on the response of the host to the carcinogen. Male and female C57BL/Ka mice, 1-2 months of age, were given 1 mg of N-nitrosobutylurea daily for 115 days; female ICR/JCL received 2-5 mg for a shorter time; all females and 90% of the males developed lymphoblastic leukemia which originated in the thymus with or without general spread, and which was transplantable to adult syngeneic recipients by i.p. inoculation of leukemia

cells. A slight or moderate degree of sustained hypoplasia in both myeloid and lymphoid systems accompanied by a lowering of the immunological competence was observed during the incubation period. Male and female inbred ACI rats, 2 months of age, kept on 5 mg/day of N-nitrosobutylurea for 125 days, developed leukemia (90%) with little or no evidence of thymus and lymph node involvement. No leukemia occurred in 10 female W/Fu rats which had been treated with the carcinogen, but all 10 animals developed mammary adenocarcinomas between 127 and 200 days after the start of N-nitrosobutylurea administration.

0093 EFFECT OF STRESS ON FORMATION OF STOMACH TUMOR IN RATS BY N-METHYL-N'-NITRO-N-NITROSOGUANIDINE. (E.) Takahashi, A. (Natl. Inst. Hyg. Sci., Tokyo, Japan), K. Onoda, K. Kawashima, R. Kato, Y. Omori and M. Ishidate. *Gann* 61(3):295-296, 1970.

The relationship between stomach cancer and stomach ulcer was investigated by feeding a carcinogen, N-methyl-N'-nitro-N-nitrosoguanidine, to rats in which stomach ulcers had been induced by acute stress. Rats given 0, 30 mg/l or 90 mg/l of the carcinogen in drinking water but which were not subjected to stress did not develop any tumors in the stomach and intestine; rats receiving no carcinogen but subjected to acute stress (immobilization in a stress-cage and immersion in 23°C water for 16 hr) developed ulcers in the glandular stomach, but no tumors were observed. Solid tumors in the glandular stomach were observed in all rats subjected to stress and carcinogen treatment. One or more adenomatous hyperplastic nodules and fibrosarcomas developed in the stomach (3-6 mm diameter) and in the duodenum (5-20 mm diameter).

0094 ELECTRON MICROSCOPIC STUDIES ON CULTURED RAT LIVER CELLS TRANSFORMED BY 4-NITROQUINOLINE-1-OXIDE. (E.) Koshiba, K. (Okayama U. Med. Sch., Japan), M. Namba and T. Oda. *Gann* 61(3):233-238, 1970.

Liver cell cultures from male rats were exposed to 10^{-6} M 4-nitroquinoline-1-oxide; electron microscopy was performed on control cells, carcinogen-transformed test cells, solid and ascites tumors produced by i.p. back-transplantation of the transformed cells, and cells cultivated from the ascites tumor. The control cells probably originated from hepatic parenchymal cells. However, no specific features of liver cells *in vivo* were observed in the control liver cells in long-term culture and identification of the cultured liver cells was unsuccessful. The electron microscopic studies on the 4-nitroquinoline-1-oxide-transformed cells revealed vacuolization of Golgi bodies, irregular nucleus, and swelling of rough endoplasmic reticulum and mitochondria. The ultrastructural observation of the control cells and the tumor cells transformed by 4-nitroquinoline-1-oxide indicated that a mixed population of cells with different origin, at least two kinds of cells, the liver cells and the cells other than liver cells, were contained in the culture originating from the rat liver tissues. It appears from these findings that these two kinds

f cells are transformed in culture by 4-nitroquinoline-1-oxide and that the tumor produced by the back-transplantation of cells treated with the carcinogen contains the 2 types of cells.

0095 EFFECT OF ALKYL BENZENESULFONATE AS A VEHICLE FOR 4-NITROQUINOLINE-1-OXIDE ON GASTRIC CARCINOGENESIS IN RATS. (E.) Takahashi, M. (Med. Sch. Nagoya City U., Japan). *Gann* 61(1): 7-33, 1970.

The effect of alkylbenzenesulfonate as a vehicle for 4-nitroquinoline-1-oxide on gastric carcinogenesis was studied in rats. Rats were divided into groups which were given (by esophageal intubation) 1 mg of 4-nitroquinoline-1-oxide in 1 ml of 0% ethanol with 8% alkylbenzenesulfonate 2-3 times a week for 18 weeks, or the same dose in 1 ml of 0% ethanol alone, or 1 ml of 20% ethanol with 8% alkylbenzenesulfonate without 4-nitroquinoline-1-oxide for controls. No neoplasms of the stomach or other organs were seen in the controls. Of 15 treated animals in the first group, 2 adenocarcinoma, 1 hemangiosarcoma, 1 hemangioma, 2 cases of atrophic gastritis, papillomas of the forestomach, 5 squamous cell carcinomas, and 2 giant squamous cell papillomas were found. In the group with the carcinogen without the surfactant, only benign papillomas of the forestomach were found in 9 rats and 1 case of liver sarcoma was found. The surfactant alkylbenzene sulfonate appeared to increase the carcinogenicity of 4-nitroquinoline-1-oxide.

0096 INHIBITORY EFFECT OF ALUMINUM ON THE DEVELOPMENT OF EXPERIMENTAL LUNG TUMOR IN MICE INDUCED BY 4-NITROQUINOLINE-1-OXIDE. (E.) Kobayashi, T. (Sch. Med., Chiba U., Japan), H. Katsuki and Y. Iizumi. *Gann* 61(3):239-244, 1970.

The effect of aluminum compounds on the development of experimental lung tumors induced by 4-nitroquinoline-1-oxide was investigated in female dd strain mice. Prior to s.c. injection with 0.25 mg of 4-nitroquinoline-1-oxide once a week for 5 weeks, the animals were made to inhale 0.2% $AlCl_3$ solution or Al_2O_3 daily for 1 week; further inhalation was continued twice a week for 7 months after the 4-nitroquinoline-1-oxide treatment. In animals treated with $AlCl_3$ or Al_2O_3 and 4-nitroquinoline-1-oxide, 60% and 70%, resp., of the animals developed a small lung adenoma without development of adenocarcinoma. All animals treated with 4-nitroquinoline-1-oxide alone developed multiple lung adenoma and 2 animals developed adenocarcinoma. The results indicate that the incidence of lung adenoma declined with the administration of aluminum, and that aluminum may inhibit the induction of adenomatous change in the lungs of mice by 4-nitroquinoline-1-oxide.

0097 CHROMOSOME ABERRATIONS AND PERSISTENT NUCLEOLI OF YOSHIDA SARCOMA CELLS INDUCED BY 4-NITROQUINOLINE-1-OXIDE *IN VITRO*. (E.) Sasaki, H. (Sasaki Inst., Tokyo, Japan). *Gann* 61(2): 193-196, 1970.

The treatment of cultured rat Yoshida sarcoma cells with 4-nitroquinoline-1-oxide (10^{-8} M) induced chromosome aberrations and persistent nucleoli. Examination of 958 metaphase cells (471 treated with 4-nitroquinoline-1-oxide, 487 control cells) showed more increased chromatid gap, chromatid break and chromatid exchange in the carcinogen-treated cells. The occurrence of chromatid break reached the highest level at 13 culture hr and then decreased gradually. The high frequency of chromatid exchange was seen during the decreasing period of the break, showing a gradual rise with the maximum at 30 culture hr and then decreased. After 48 hr, the frequency of chromosome aberrations in the carcinogen-treated group was at the same level as that in the control. Cytopathological examinations of 4-nitroquinoline-1-oxide-treated cells revealed prominent nucleoli in late prophase, prometaphase and metaphase cells within 30 hr when the chromosome aberrations were frequent.

0098 CHROMOSOMAL ALTERATION AND THE DEVELOPMENT OF TUMORS: XX. CHROMOSOME CHANGE IN THE COURSE OF MALIGNANT TRANSFORMATION *IN VITRO* OF HAMSTER EMBRYONIC CELLS BY 4-NITROQUINOLINE 1-OXIDE AND ITS DERIVATIVE, 4-HYDROXYAMINOQUINOLINE 1-OXIDE. (E.) Yosida, T. H. (Natl. Inst. Genet., Shizuoka, Japan), T. Kuroki, H. Masuji and H. Sato. *Gann* 61(2):131-143, 1970.

Golden hamster embryonic cells were transformed to malignancy *in vitro* by treatment with 4-nitroquinoline-1-oxide and its derivative, 4-hydroxyaminoquinoline-1-oxide ($4 \times 10^{-5.5}$ and $10^{-4.5}$ M, resp.), and the chromosomes were examined with special regard to karyotype change in different stages of malignant transformation. In 5 of 11 transformed cell lines the chromosome numbers had a tetraploid mode, a diploid mode in 4, and in the remaining 2 the distribution was bimodal with a tetraploid and a diploid peak; one spontaneously transformed line showed a hyperdiploid mode. Generally, cells at an early stage of malignant transformation by carcinogen treatment had diploid or near-diploid chromosome number, but at later stages after transformation they had near-tetraploid chromosome numbers. Karyotypes of cells with diploid chromosome number, however, deviated more or less from those of normal somatic cells. The first event of cell transformation on the chromosomal level seems to consist of structural chromosome changes, such as gaps, breaks, and deletion, whereupon heteroploid and polyploid karyotype changes follow due to non-disjunction and/or duplication of chromosome sets.

0099 INFLUENCE OF THYMECTOMY, SPLENECTOMY, AND CORTISONE ON CARCINOGENESIS. (It.) Della Porta, G. (Natl. Tumor Inst., Milan, Italy), M. I. Colnaghi and L. Parmi. *Tumori* 56(2):121-135, 1970.

The effects of thymectomy, splenectomy and cortisone treatment on urethan carcinogenesis in mice were studied in 3 experiments; and the effect of thymectomy on tumor incidence without a urethan treatment was studied in a 4th experiment. Groups of outbred

albino CTM mice were either thymectomized or splenectomized at 4 weeks of age and administered urethan 0.4% in drinking water for 10 days at 5 weeks. In comparison with intact, urethan-treated animals, the thymectomized, urethan-treated mice had a slightly lower incidence of malignant lymphomas (19% vs 24%), a marked decrease of mammary tumors (31% vs 62%), and increased incidence of lung adenomas (84% vs 48%) and of skin papillomas (10% vs 1%). Thymectomized, but otherwise untreated mice developed less lymphomas and mammary tumors than intact, untreated controls, while splenectomy did not modify significantly the tumor incidence. In a second experiment, groups of CTM mice were administered either 1 mg of cortisone s.c. daily for 10 days or urethan in the drinking water for 5 days followed by 5 days of cortisone or vice versa, or urethan alone. No major differences in the tumor incidence in the various groups were observed, apart from a decreased incidence of thymic lymphosarcomas in the group with cortisone after urethan. In a third experiment, CTM mice were given 2 mg urethan within the 1st day after birth and thymectomized or sham-operated; both groups had a high incidence of hepatomas and lung adenomas, and developed only few lymphomas and mammary tumors. In the fourth experiment, the C3H mice thymectomized at birth developed fewer hepatomas and mammary tumors than sham-operated animals.

- 0100 TUMOR INDUCTION WITH SINGLE URETHAN INJECTION IN NEWBORN AND ADULT SYRIAN GOLDEN HAMSTERS: A STUDY ON AGE INFLUENCE. I. (E.) Toth, B. (U. Nebraska Coll. Med., Omaha). *Int J Cancer* 6(2):63-68, 1970.

The administration of urethan (1 mg/kg s.c.) to Syrian golden hamsters (newborn and 8 wks old) caused a higher incidence of forestomach papilloma in animals receiving urethan as adults (33%) than at birth (23%). Urethan administration gave rise to similar incidences of dermal melanocytomas in the 2 age groups. Other tumors were also observed in the animals. Since only a few were seen of each type, it is difficult to relate their appearance to the treatments. It is concluded that age is a factor in the oncogenic response of golden hamsters challenged by a single chemical stimulus.

- 0101 RECOVERY FROM THE INHIBITORY EFFECT OF X-RADIATION ON URETHAN LUNG ADENOMAGENESIS. (E.) Bartlett, G. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.). *Int J Cancer* 6(1):56-62, 1970.

The reversibility of radiation-induced inhibition of urethan lung tumors was studied in male (C₃HfB/He x A/He)F₁ mice irradiated with 500 r 24 hr or 2 weeks prior to the administration of urethan for 3 days. After 260 days, thymectomized, urethan-treated mice developed an average of 6.8 tumors each, while mice irradiated 24 hr prior to urethan treatment developed only 2.1 tumors each. Animals irradiated 2 weeks prior to urethan administration developed an average of 4.8 tumors each; thymectomized mice which had been irradiated 2 weeks prior to urethan treatment developed 5.6 tumors each. The immunity to urethan-induced tumors conferred by a sublethal dose

of radiation seemed to be transient and the recovery process was not dependent on the thymus.

- 0102 CHROMOSOMAL ALTERATION AND DEVELOPMENT OF TUMORS: XXI. CYTOGENETIC STUDIES OF PRIMARY PLASMA-CELL NEOPLASMS INDUCED IN BALB/c MICE. (E.) Yoshida, T. H. (Natl. Inst. Genet., Misima, Japan), H. T. Imai and K. Moriwaki. *J Nat Cancer Inst* 45(3):411-418, 1970.

Intraperitoneal injection of 0.5 ml of Freund adjuvant produced plasma cell tumors in the peritoneum of 19 mice; chromosomal studies were performed on 14 primary tumors. Of these, 3 had diploid, 1 had hypodiploid (44), and the remaining 10 had hypotetraploid or hypertetraploid chromosomes. In tumors developing shortly after treatment, diploid or near-diploid cells were more frequent, whereas in those appearing a long time after treatment, polyploid cells were more frequent. Diploidy of primary tumors changed to near-tetraploidy after 1-2 transplant generations. Mouse plasma cell tumors can apparently develop from cells with diploid chromosome numbers, but then can change to aneuploidy during further growth.

- 0103 THE USE OF CARRAGEENAN AS A GRANULOMA-PRODUCING AGENT IN FREUND'S ADJUVANT. (E.) Salvaggio, J. (Louisiana St. U. Med. Sch., New Orleans) and V. Kundur. *Proc Soc Exp Biol Med* 134(4):1116-1119, 1970.

Carageenan was substituted for mycobacteria in complete Freund's adjuvant and observations on antibody production and delayed hypersensitivity to crystalline bovine serum albumin were made on guinea pigs. The carageenan-Freund's adjuvant administered in dose ranges of 0.025-2.5 mg resulted in marked reduction in intensity of delayed hypersensitivity to incorporated protein antigen (4-9 mm of induration and erythema); *M. tuberculosis* adjuvant reactions ranged from 10-27 mm. Carageenan also failed to enhance γ 2 anti-BSA titers (20-160), when compared with mycobacterial adjuvant (640-5120). Animals receiving carageenan developed small draining nodes in contrast to the large hypertrophied and hyperplastic nodes after mycobacterial adjuvant.

- 0104 PROGRESS REPORT ON STUDY OF RESPIRATORY SPIRALS. (E.) Walker, K. R. (Holy Cross Hosp., Salt Lake City, Utah) and C. D. Fullmer. *Acta Cytol* 14(7):396-398, 1970.

The incidence of Curschmann respiratory spirals in the sputum of cigarette smokers was investigated. The sputum and smoking histories of 20 patients were examined and compared to see if there was a relationship between the amount smoked and numbers of spirals produced. Spiral counts ranged from 1 to 916 spirals per aliquot of sputum. However, although 94% of the smokers produced spirals, no direct or general rise in numbers of spirals was seen as the amount and number of years smoked increased.

- 0105 CARCINOGENIC EFFECT OF CIGARETTE TAR USING NEWBORN ICR MICE. (E.) Takayama, S. (Cancer Inst., Tokyo, Japan). *Gann* 61(3):297-298, 1970.

The carcinogenic effect of cigarette tar in newborn mice was investigated by s.c. injection of 0.025 ml or 0.05 ml of a 10% olive oil solution of tar in the interscapular region within 24 hr after birth or an injection of 0.05 ml of olive oil as control. Twelve out of 20 mice injected with 0.025 ml of the tar solution, and 16 out of 26 mice receiving 0.05 ml of the tar solution developed tumors of the liver, lung and lymphoma; control mice had a tumor incidence of 4 in 6.

- 0106 THIN-LAYER CHROMATOGRAPHY OF 4-(4'-NITROBENZYL)-PYRIDINE-REACTIVE COMPOUNDS IN TOBACCO SMOKE. (E.) Norpoth, K. (Hyg. Inst. U. Munster, Germany) and T. Papatheodorou. *Naturwissenschaften* 57(7):356, 1970.

Tobacco smoke condensate was fractionated by thin-layer chromatography and reacted with 4-(4'-nitrobenzyl)pyridine to detect alkylating activity. A 4-(4'-nitrobenzyl)pyridine-positive band was detected in the water-soluble portion of the tobacco smoke condensate; extracts of tobacco did not contain this compound. Five or more other 4-(4'-nitrobenzyl)pyridine-positive bands were found in the neutral ether extracts of both the tobacco smoke and tobacco extracts.

- 0107 *IN VIVO* AND *IN VITRO* CILIOTOXIC EFFECTS OF TOBACCO SMOKE. (E.) Dalhamn, T. (Inst. Hyg., U. Uppsala, Stockholm, Sweden). *Arch Environ Health* 21(5):633-634, 1970.

Tobacco smoke exposure in doses ("puffs") of 1 ml and 10 ml produced ciliostasis in rabbit trachea *in vitro* and in cat trachea *in vivo*. One ml exposure required 3 puffs and 71 puffs to produce ciliostasis in rabbit trachea and cat trachea, resp. In the experiments with 10 ml puffs, 37 puffs and 35 puffs were required to produce ciliostasis. Since it is apparently a matter of indifference in the production of ciliostasis whether the *in vivo* or the *in vitro* technique is used, the method of preparing trachea specimens might be simplified to permit *in vitro* techniques and the use of fewer animals.

- 0108 OF BEAGLES, SMOKING, AND CANCER. (E.) Anonymous *Roche Med Image Comment* 12(7):1-13, 1970.

Two related studies designed to induce lung cancer in beagles by cigarette smoking are reported; cigarette smoke was pumped into the beagles' lungs through tracheostomy tubes. In a pilot study using 10 beagles, after 420 days of heavy smoking, epithelial lesions were observed in the lungs of most dogs, lesions which may form a phase in the development of carcinoma *in situ*. In the full scale study, 86 beagles smoked filter and nonfilter cigarettes for as long as 875 days, with the result that invasive bronchioalveolar tumors were observed, as were early

invasive squamous cell carcinomas of the bronchii similar to those observed in the lungs of humans with lung cancer. Tumor formation was directly correlated with number of nonfilter cigarettes smoked; beagles smoking filter cigarettes had a lower rate of tumor incidence per number of cigarettes smoked than beagles smoking nonfilter cigarettes.

- 0109 MORTALITY IN SMOKING DISCORDANT MONOZYGOTIC AND DIZYGOTIC TWINS: A STUDY ON THE SWEDISH TWIN REGISTRY. (E.) Friberg, L. (Karolinska Inst., Stockholm, Sweden), R. Cederlof, T. Lundman and H. Olsson. *Arch Environ Health* 21(4):508-513, 1970.

Data on mortality, including cause of death, in smoking discordant monozygotic and dizygotic twin pairs from Sweden showed an excess mortality among male dizygotic smokers that was not associated with any specific cause of death. The 4 cases of death from lung cancer among dizygotic men occurred only among smokers; the 1 case of lung cancer mortality in the monozygotic group occurred in the nonsmoking twin. Other forms of cancer accounted for 8 deaths among dizygotic male smokers, and for 3 deaths among dizygotic male nonsmokers. Among women, death from lung cancer occurred only in the case of 1 subject, a dizygotic smoker, and deaths from other cancers occurred in 8 nonsmoking dizygotic twins, and in 7 smoking dizygotic twins. Monozygotic women accounted for 3 deaths from cancers other than lung cancer in both the smoking and nonsmoking categories.

- 0110 CANCER OF THE BLADDER IN PATIENTS TREATED WITH CHLORNAPHAZINE. (E.) Laursen, B. (Gentofte Hosp., Copenhagen, Denmark). *Brit Med J* 3(5724):684-685, 1970.

The development of cancer of the bladder in 2 women who had, 5 and 6 yr previously, been treated with chlornaphazine for Hodgkin's disease, is reported. In both cases, X-irradiation had also been used in treating the original complaint, with irradiation affecting the pelvic lymph nodes in 1 case, and the neck, axillae, supraclavicular regions and mediastinum in the other case. Biopsies of the bladder revealed papillomatous carcinoma grade I in 1 case, and an atypical epithelium and urothelium corresponding to a grade III noninvasive carcinoma in the other case. Chlornaphazine is thought to be the most likely cause of bladder cancer in the 2 cases.

- 0111 HEALTH CONSIDERATIONS IN THE USE OF ORGANIC REACTOR COOLANTS. (E.) Weeks, J. L. (Whiteshell Nucl. Res. Estab., Pinawa, Manitoba, Canada) and B. C. Lentle. *J Occup Med* 12(7):246-252, 1970.

The toxicity and carcinogenicity of terphenyls, which are used as comparatively inexpensive organic coolants in nuclear reactors, were studied in 47 persons exposed to the organic coolant for periods of at least 6 months to 7 yr and in 47 matched

controls. The exposure group showed no untoward incidence of tumor formation. Pulmonary function, hematological investigations, and serum isocitric dehydrogenase levels were the same in both groups. Although observation over a longer term will be necessary to determine any carcinogenic effects of terphenyl, available information does not suggest that this will be a likely hazard.

- 0112 CHROMOSOME DAMAGE AFTER OCCUPATIONAL EXPOSURE TO LEAD. (Ger.) Schwanitz, G. (Inst. Human Genet., U. Erlangen-Nuremberg, Germany), G. Lehnert and E. Gebhart. *Deutsch Med Wschr* 95(32):1636-1641, 1970.

To investigate the correlation between chromosomal damage and occupational exposure to lead, chromosomal analyses and biochemical tests were performed on workers in a lead-oxide factory, where all subjects were found to have a significantly elevated blood lead level (74.7 $\mu\text{g}/100\text{ ml}$ vs normal value of 14.9 $\mu\text{g}/100\text{ ml}$). Blood lymphocyte cultures showed an increased proportion of mitoses with secondary chromosomal aberrations in the workers exposed to lead-oxide, compared with a control group of healthy blood donors. The percentage of abnormal mitoses rose with an increasing δ -aminolevulinic-acid excretion in the urine. In addition to chromosomal breaks there were also nonspecific changes such as spiralizing defects, chromosomal adhesions and pulverization. The proportion of tetraploid mitoses and the mitoses index were slightly increased over those in the control group. *In vitro* experiments with lead acetate solution (10^{-4} to 10^{-6} M) confirmed the abnormalities found in the lead workers. The proportion of abnormal mitoses was largely independent of the added lead acetate concentration.

- 0113 NASAL CANCER IN WOODWORKERS. (E.) Anonymous. *Lancet* 2(7666):253, 1970.

A high correlation between nasal cancer and wood-working was found among woodworkers in the furniture industry in England (29 of 35 patients in one study were woodworkers). Adenocarcinomas, usually originating in the ethmoid sinus, were especially common. Early presenting symptoms included unilateral blood-stained nasal discharge and unilateral nasal obstruction. Wood dust apparently becomes deposited in 2 areas anteriorly on the nasal septum and on the anterior part of the middle turbinate, a frequent site of squamous metaplasia. Prolonged contact of wood dust, which probably contains a carcinogen, with the mucous membrane in the middle turbinate may stimulate tumor formation.

- 0114 CARCINOMA OF THE PENIS INVOLVING SKIN OF BASE. (E.) Grabstald, H. (Mem. Hosp. New York, N.Y.). *J Urol* 104(3):438-440, 1970.

A case of rare skin cancer affecting the base of the penis and diagnosed as low-grade squamous cell carcinoma of the penis is presented. The lesion was noted in a house painter exposed to paints and paint removers for more than 40 yr. A wide local

excision of the tumor which included virtually all of the skin of the penis was done. Radical groin dissection was not carried out. The patient has been free of disease for more than 3 yr postoperatively. Whether the patient's occupation was related to the tumor is not clear.

- 0115 A STUDY OF MORTALITY, SYMPTOMS, AND RESPIRATORY FUNCTION IN HUMANS OCCUPATIONALLY EXPOSED TO OIL MIST. (E.) Ely, T. S. (Lab. Indust. Med., Eastman Kodak Co., Rochester, N.Y.), S. F. Pedley, F. T. Hearne and W. T. Stille. *J Occup Med* 12(7):253-261, 1970.

The incidence of malignant and benign neoplasms was assessed in a study of people occupationally exposed to oil mist concentrations in machine shop environments. Measures of forced vital capacity and one second forced expiratory volume were compared in unexposed control groups and in exposed test groups. The significant predictors of forced vital capacity and forced expiratory volume for the groups studied were consistently height, age, and cigarette years. The symptoms in general yielded the smoking variables, as well as disease history in some cases, as the significant predictors. After the effect of these predictors had been taken into account, the effect of oil-mist exposure or any other job environment, as measured by the number of years on that job, was found to be not significant. Practical machine shop oil mist concentrations experienced by the experimental group were not associated with an increase in any respiratory symptom, including carcinoma-related symptoms.

- 0116 CARCINOMA OF THE SCROTUM. (E.) Milne, J. E. H. (Dept. Hlth., Victoria, Australia). *Med J Aust* 57(1):13-16, 1970.

Five cases of carcinoma of the scrotum were followed up to determine if occupational factors figured in the etiology of the disease. All cases occurred during or after the seventh decade of life (67-88 yr). In 4 of the 5 cases, the subjects had been continuously exposed to oil and grease in the course of their working lives in machine shops, railroad yards and coal mines, following the general pattern of scrotal cancer observed in larger studies. Use of protective outer clothing and personal hygiene, especially skin cleansing, can lower the risk of exposure to those who work with carcinogenic oils.

- 0123 EFFECTS OF SINGLE-DOSE, WHOLE BODY, ^{60}Co GAMMA IRRADIATION ON NUMBER OF CELLS IN DNA SYNTHESIS AND MITOSIS IN THE MOUSE DUODENAL EPITHELIUM. (E.) Leshner, J. (Allegheny Gen. Hosp., Pittsburgh, Pa.) and S. Leshner. *Radiat Res* 43(2):429-438, 1970.

The number of cells in mitosis and in DNA synthesis in the mouse duodenal epithelium after single-dose, whole body ^{60}Co γ -ray exposures (150, 300, 500, 600, 750, and 1000 r) have been studied with crypt squash autoradiographs by injecting ^3H -thymidine (50 μC , i.p.) at various postirradiation intervals. Changes in the number of cells in mitosis and DNA synthesis after irradiation followed a similar pattern at all dose levels but the degree of change increased with increasing dose. Mitosis was completely blocked for 1 hr after exposure at all levels; then a mitotic lag ranging from 1.5 to 10 hr was observed, followed by a mitotic rate which exceeded control values and went through a series of fluctuating highs and lows damping to a near steady-state cell proliferation rate. The number of cells in DNA synthesis decreased after irradiation for an extended period (10-60 hr) and then exceeded the control values before damping to normal. The immediate block of cells in G_1 and G_2 by irradiation was followed by a rapid rise in the number of cells in mitosis and DNA synthesis, after which cell production returned to normal levels.

- 0124 ISCHEMIA OF THE LUNG DUE TO IONIZING RADIATION: QUANTITATIVE STUDIES. (E.)

Johnson, P.M. (Coll. Phys. Surg., Columbia U., New York, N. Y.), R. H. Sagerman and C. S. Dombrowski. *J Nucl Med* 11(8):491-495, 1970.

Adult female mice were exposed to ionizing irradiation of the right lung in doses ranging from 100-4,000 rads to determine the incidence and severity of pulmonary ischemia consequent to irradiation. Pulmonary blood flow was reduced following radiation; the intensity of radiation-induced pulmonary ischemia was affected by the size of the radiation dose and the length of survival following treatment. During survival periods extending to half the life span of the animal, no evidence could be found of a limiting process or of recovery from radiation-induced pulmonary ischemia.

- 0125 ATYPICAL CHANGES IN THYROID FOLLICULAR CELLS SECONDARY TO RADIOIODINE. (E.)

Murphy, E. (Nat'l. Comm. Nucl. Med., Mexico City, Mexico) and Q. F. B. C. Cervantes. *Amer J Roentgen* 109(4):724-728, 1970.

Rats were injected with 150-700 μC radioiodine 131 to test whether this agent causes atypical cellular changes in thyroid follicles connected with neoplasia. High doses of radioiodine 131 produced marked follicular atrophy with moderate and irregular nuclear enlargement and few mitotic forms. Rats injected with 0.4-2.5 U thyroid stimulating hormone in association with radioiodine revealed microscopic cellular alterations of greater importance than those revealed by rats which did not receive thyroid stimulating hormone.

- 0126 PAPILLARY ADENOCARCINOMA OF THE THYROID DEVELOPING AFTER TREATMENT OF HYPERTHYROIDISM WITH ^{131}I . (E.) Araki, M. (Res. Inst. Nucl. Med. Biol., Hiroshima U., Japan) and K. Oshiro. *Gann* 61(3):267-269, 1970.

A case of papillary carcinoma developing in the thyroid of a Japanese woman, 6 yr after ^{131}I treatment for hyperthyroidism, is reported. The resected tumor was 1.8 x 1.2 x 0.6 cm and surrounded by a capsule composed of concentric layers of collagenous connective tissue. The lesion was well-differentiated, admixed with irregular islands of hyaline connective tissue; the individual cells were small, with distinct vesicular nuclei surrounded by scant eosinophilic cytoplasm. Scattered foci of calcification were present and mitotic figures were rare. The surrounding thyroid tissue was characterized by irregular interstitial fibrosis, consistent with late irradiation changes.

- 0127 WHOLE BODY IRRADIATION OF THE RAT: LATE PULMONARY LESIONS. I. HISTOCHEMICAL STUDIES. (Fr.) Caulet, T. (Fac. Med. Reims, France), J. J. Adnet, M. Pluot and G. Legeay. *Path Europ* 5(2):164-178, 1970.

Histological and histochemical alterations in Wistar rat lungs (88 animals) following whole body irradiation (single exposure, ranging from 100-800 rad) were studied 2-13 months after exposure. Slight sclerotic lesions were noticed sporadically in animals exposed to 400 rad. Collagenous interstitial fibrosis occurred 3-4 months after 500-600 rad exposures; such fibrosis appeared most severe in the lungs of animals exposed to 600, 700 and 800 rad. The interalveolar wall appeared thickened and lined with membranous and granular (phospholipid inclusions) pneumocytes. Emphysema associated sclerotic lesions occurred in animals injected intratracheally with homologous heparinized blood, before or after irradiation; such lesions were characteristically seen 5-12 months after exposure to 500 or 600 rad. Of the hydrolases, acid phosphatase levels increased within the endoalveolar cells and alkaline phosphatases increased within the granular pneumocytes; ATP-ases and 5-nucleotidases increased in areas of hypertrophic reticular pneumonia while esterases increased throughout the cell system. The dehydrogenases increased in all cell types except in the areas of reticular atrophic pneumonia; lactic and glucose-6-phosphate dehydrogenases appeared most elevated, indicating intense local oxidative processes, probably due to the operation of repair mechanisms.

- 0128 WHOLE BODY IRRADIATION OF THE RAT: LATE PULMONARY LESIONS. II. MORPHOLOGY AND CYTOCHEMISTRY, AN ELECTRON MICROSCOPY STUDY. (Fr.) Adnet, J. J. (Fac. Med. Reims, France), T. Caulet, G. Legeay, C. Hopfner and J. L. Guenet. *Path Europ* 5(2):179-197, 1970.

Morphological and cytochemical alterations of lung ultrastructure (alveolar wall and cell lining) were studied in 40 Wistar rats 8 weeks to 11 months following whole body irradiation (single exposure to

levels ranging from 100-800 rad). An additional 21 rats were injected intratracheally with homologous parinized blood in order to study whole body radiation effects on modified lung parenchyma. Minor lesions induced by 100-400 rad levels consisted of slight collagenous scleroses of the alveolar wall, occurring during the second month after exposure. Major lesions, produced by 500-800 rad, consisted of severe fibrosis of the alveolar wall, associated with the occurrence of considerable numbers of mastocytes, dilatation of wall capillaries and an increase of the amount of granular pneumocytes. The blood-treated rats (exposed to 100-800 rad) developed sclerotic emphysema. Acid phosphatases occurred at the lamellar level of granular pneumocytes in cytolytic areas induced by irradiation; alkaline phosphatases were present around the lung capillaries in sclerotic areas above the 600 rad level of exposure, indicating severe circulatory alterations. Dehydrogenases disappeared in the regions of altered granular pneumocytes. Labeled glycine incorporation occurred normally in unaltered granular pneumocytes up to 800 rad levels of exposure, but failed to occur in altered pneumocytes.

29 PROTECTION BY CYSTEAMINE AGAINST MITOTIC DELAY AND CHROMOSOMAL ABERRATIONS INDUCED BY X-RAYS IN SYNCHRONIZED CHINESE HAMSTER CELLS. (E.) C. K. (Argonne Natl. Lab., Ill.) and W. K. Sinclair. *Radiat Res* 43(2):357-371, 1970.

The protective effect of cysteamine (50 mM) on mitotic delay and chromosomal aberration frequency induced by X-irradiation was studied at different stages of the cell cycle in Chinese hamster lung cells (79-S171). Cells not treated with cysteamine and irradiated (625 r) during the S phase showed greater mitotic delay (3-4 hr) than those irradiated in G₁ and (2 hr); cells not irradiated but treated with cysteamine showed delay (1 hr) when treated during the early S and a small delay (30 min) when treated in late S or G₁. Treatment of cells with both irradiation (1500 r) and cysteamine produced a pattern similar to that of cells irradiated without cysteamine except that the required irradiation dose was 2.4 times higher. The dose-modifying factor for mitotic delay was approximately 2.5 throughout the cell cycle. Data on chromosomal aberrations in irradiated (3000 r) cells in the presence of cysteamine indicate that the frequency of aberrations and their distribution were similar to those observed without cysteamine except that the required dose was more than 5 times higher. The dose-modifying factor for aberrations resulting from one hit is approximately 8, and 5.3 for two-hit aberrations.

30 PHILADELPHIA CHROMOSOME IN ACUTE LYMPHOCYTIC LEUKEMIA. (E.) Propp, S. (Albany Med. Coll., Union U., New York) and F. A. Luzzi. *Blood* 36(3):353-360, 1970.

A case of acute lymphocytic leukemia associated with a high percentage of Philadelphia chromosome in the marrow cells is presented. The patient was a roent-

genologist who had been practicing diagnostic radiology, including fluoroscopy, for 11 yr preceding his final illness. Repeated exposure to X-ray irradiation may have caused chromosome damage resulting in the occurrence of the Philadelphia anomaly in lymphocytic leukemia in his case. No Philadelphia chromosome was observed in a 72-hr blood culture using phytohemagglutinin in 50 metaphases counted, which ruled against a congenital defect. The specificity of the Philadelphia chromosome for myeloproliferative disorders should be reconsidered.

0131 ORIGIN OF UNDIFFERENTIATED NEOPLASM FROM VERRUCOUS EPIDERMAL CARCINOMA OF ORAL CAVITY FOLLOWING IRRADIATION. (E.) Kosek, J. C. (VA Hosp., Palo Alto, Calif.), S. D. Proffitt and T. R. Spooner. *Cancer* 26(2):389-393, 1970.

A case is presented of a 61-yr-old man bearing a verrucous carcinoma of the oral cavity which appeared to have undergone anaplastic transformation, an unusual finding in carcinomas of this type. The carcinoma had been treated by X-irradiation. The anaplastic lesion had definite epidermoid differentiation in the form of tonofibrils and tonofilaments, demonstrable only with electron microscopy. It co-existed discretely with the well-differentiated tumor and metastasized independently. Probably, the former lesion arose, not through a transformative dedifferentiation, but as a new carcinoma from the cells of the latter lesion.

0132 POSTIRRADIATION SARCOMA: INCLUDING 5 CASES AFTER X-RAY THERAPY OF BREAST CARCINOMA. (E.) Hatfield, P.M. (Massachusetts Gen. Hosp., Boston) and M. D. Schulz. *Radiology* 96(3):593-602, 1970.

Postirradiation sarcoma was exhibited by 11 patients in a 15-yr survey at Massachusetts General Hospital; sarcomas in such sites as the shoulder, chest, and pelvis, occurred after radiation treatment of primary carcinoma of the breast in 5 cases, and after megavoltage therapy in 3 cases. Because these lesions developed, on an average of about 8 yr after therapeutic exposure to radiation, it is probable that they were caused by radiation and were not examples of the "double primary" phenomenon or of spontaneously occurring osteogenic sarcoma. The frequency of post-irradiation sarcoma of bone in 10-yr survivors of radiation treatment for carcinoma of the breast is estimated to be about 1 post-irradiation sarcoma for every 450 radiation-treated and cured breast carcinomas.

0133 RADIATION-INDUCED SARCOMA AFTER TREATMENT OF BREAST CANCER. (E.) Senyszyn, J. J. (Columbia-Presbyterian Med. Ctr., New York, N. Y.), A. D. Johnson, H. W. Jacox and F. C. H. Chu. *Cancer* 26(2):394-403, 1970.

Radiation-induced sarcomas after treatment of breast carcinoma is reported in 2 patients 23 yr and 7 yr after radiotherapy. An undifferentiated sarcoma of the scapula believed to be induced by a calcu-

lated dose to the soft tissue component of bone of 8,195 rads in 3 weeks was found in one patient. The second patient had a fibrosarcoma involving the soft tissues of the axilla. Both patients died several months after diagnosis of the second neoplasm.

- 0134 ECCRINE POROMA: TWO UNUSUAL VARIANTS. (E.) Penneys, N. S. (U. Miami Sch. Med., Florida), A. B. Ackerman, S. N. Indgin and S. H. Mandy. *Brit J Derm* 82(6):613-615, 1970.

Two cases of eccrine poroma are described which were regarded as atypical in that one affected the nose, and one occurred in an area of radiation-altered skin. In Case 1, in the region of chronic radiodermatitis in which the eccrine poroma originated, akinetic keratosis, squamous cell carcinomas and an atypical fibroxanthoma had developed. The irradiated area had been affected previously with several cutaneous malignancies; the other hand had been affected by numerous tumors, including atypical fibroxanthoma, squamous cell carcinomas, Bowen's disease, and several keratoses. An unusual feature of the eccrine poroma in Case 2 was the presence of numerous mitotic figures.

- 0135 MALIGNANT ADENOMA OF THE THYROID OCCURRING AFTER ROENTGEN THERAPY IN CHILDHOOD. (Ger.) Gilly, L. (Recklinghausen Inst. Radiol., Germany) and D. Meese. *Strahlentherapie* 139(6):695-697, 1970.

An 18-yr-old male developed a malignant papillary adenoma of the thyroid 15 yr after roentgen therapy (a total of 260 rad) for bilateral cervical lymph nodes. Thyroidectomy followed by cobalt therapy led to complete recovery of the patient. Similar cases on large patient populations (minimal dose of radiation received at least 180 rad) are reviewed.

- 0136 IRRADIATION GASTRITIS SIMULATING CARCINOMA. (E.) Lane, D. (Mater Hosp., Brisbane, Australia). *Med J Aust* 57(13):576-577, 1970.

Two cases are presented in which standard deep X-ray therapy was given after nephrectomy for carcinoma of the kidney; the patients' stomachs in both cases had the radiological appearance of carcinoma, the diagnostic choice being between carcinoma of the stomach and chronic gastritis. In the first case, although there was no gastroscopic evidence of cancer, the patient finally died of metastasizing tumors in the lumbar spine, while in the second case, the final diagnosis was fibrosis secondary to X-ray treatment.

- 0137 CLINICAL, HISTOCHEMICAL AND CYTOGENETIC FINDINGS IN PATIENTS WITH THOROTRAST DAMAGE. (Ger.) Hennekeuser, H. H. (2nd Med. U. Clin. Mainz, Germany), P. Citoler, H. Niemczyk and A. Gropp. *Klin Wschr* 48(15):895-906, 1970.

Clinical, histological and cytogenetic investigations in 6 men and 3 women (40-66-yr-old), who had angio-

graphy with thorotrast 19-28 yr before, revealed 1 patient with lymphosarcoma, 3 patients with local granulomas (at the site of contrast medium injection) and 5 patients with enlarged livers. Lymphocyte cultures from the peripheral blood of all 9 patients had abnormal chromosomes while no chromosomal aberrations were detected in the bone marrow cells (thorotrast positive) of 4 examined patients. Liver needle biopsies in 6 patients revealed the presence of thorotrast, detectable by microscopy and autoradiography. Only 2 patients had fibrosis of the liver.

- 41 DNA-DIRECTED DNA POLYMERASE ACTIVITY IN ONCOGENIC RNA VIRUSES. (E.) Spiegelman, (Inst. Cancer Res., Columbia U., New York, N. Y.), Burny, M. R. Das, J. Keydar, J. Schlom, M. Travnicek and K. Watson. *Nature* 227(5262):1029-1031, 1970.

DNA-directed DNA polymerase has been detected in 6 oncogenic RNA viruses (Rauscher leukemia, Rous sarcoma, avian myeloblastosis, murine mammary tumor, Moloney sarcoma and feline leukemia viruses). DNA synthesis with all 4-deoxyriboside triphosphates, Mg^{+2} and DNA was monitored by incorporation of 3H -dATP; the viral preparations used were pretreated with micrococcal nuclease to eliminate the viral RNA. The identity of the product of the reaction was confirmed by its sensitivity to deoxyribonuclease and equilibrium density centrifugation. The response of the avian myeloblastosis viral DNA-RNA polymerase to different DNA templates (CEF, MEF, *E. coli* and T6) revealed that the oncogenic viral DNA polymerase preferred double to single stranded DNA. The results of hybridizing each of 3 DNA products to 3 DNA templates (mouse, *E. coli* and T6) showed that hybridizability of each product was much superior when challenged with the DNA actually used in its synthesis. These data suggest that the DNA polymerase of the oncogenic viruses is not copying random segments of these vertebrate DNA's.

- 42 CHARACTERIZATION OF THE PRODUCTS OF RNA-DIRECTED DNA POLYMERASES IN ONCOGENIC RNA VIRUSES. (E.) Spiegelman, S. (Inst. Cancer Res., Columbia U., New York, N. Y.), A. Burny, M. R. Das, J. Keydar, J. Schlom, M. Travnicek and K. Watson. *Nature* 227(5258):563-567, 1970.

Given tumor viruses (Rauscher murine leukemia, Moloney sarcoma, mammary tumor, feline leukemia, avian myeloblastosis, monkey mammary tumor and Rous sarcoma viruses) were purified and the incorporation of 3H -TTP into an acid-insoluble product was followed with each virus. The acid-insoluble product, after isolation and purification, could be degraded by deoxyribonuclease but not by ribonuclease, pronase or NaOH. Equilibrium density centrifugation and base frequency analysis established that the product was a DNA heteropolymer. The outcome of an annealing reaction between the DNA synthesized by Rauscher leukemia virus polymerase and excess RNA purified from the same virus resulted in complete hybridization. The specific complementarity of the DNA product to the viral RNA and the occurrence of DNA-RNA hybrids in the course of the reaction seem to establish the existence of RNA-directed DNA polymerases in the oncogenic viruses.

- 43 FORMATION OF VIRAL RNA-DNA HYBRID MOLECULES BY THE DNA POLYMERASE OF SARCOMA-LEUKEMIA VIRUSES. (E.) Rokutanda, M. (St. Louis U. Sch. Med., Mo.), H. Rokutanda, M. Green, K. Fujinaga, K. Ray and C. Gurgo. *Nature* 227(5262):1026-1028, 1970.

Evidence that the template for the DNA polymerase of the sarcoma-leukemia viruses is viral RNA is presented. ^{32}P -labeled viral RNA was used in the standard DNA polymerase assay with 3H -TTP; after 90 min, both labels

cosedimented at 70 S. Treatment with pronase and Cs_2SO_4 density gradient analysis indicated hybrid formation had occurred. Alkaline hydrolysis resulted in the release of 3H -DNA; incubation of viral ^{32}P -RNA and 3H -DNA in annealing conditions converted the DNA to a hybrid. The viral RNA-DNA hybrid is probably the initial product of the virus DNA polymerase reaction, since only small amounts of free product were found even after 90 min of reaction.

- 0144 TUMOR-INDUCED SKIN HETEROGENIZATION: II. VIRUS CAUSING THE PHENOMENON. (E.) Svet-Moldavsky, G. (Inst. Exp. Clin. Oncol., Moscow, USSR), A. L. Liozner, D. M. Mkheidze, P. P. Sokolov and A. P. Bykovsky. *J Nat Cancer Inst* 45(3):475-484, 1970.

A permanent skin-heterogenizing virus was contained in sarcoma K-237 of C57BL/6J mice; the virus was ether resistant, thermolabile and could be specifically neutralized with C57BL/6J immune serum. It caused the same phenomenon of tissue incompatibility as the tumor itself. Preliminary sedimentation data which showed the virus particles to be very small was confirmed partly by the discovery of two types of virions, 175 and 80 A in diameter, in an active fraction of the homogenate. Homogenates obtained from tumors of the 7th-22d passages contained skin-heterogenizing virus titers of 10^8 - 10^{12} heterogenization-producing doses/ml, but those obtained from tumors of the 23d-27th passages contained 10^1 - 10^5 . The state of heterogenization was maintained in infected mice from the 21st-240th day after inoculation. The behavior patterns of the virus in tumor cells were somewhat different from those of skin grafts. Apparently, the virus in the skin is in some way integrated with the cells and passes from cell to cell by some unknown mechanism. Infectious virus was obtained from the skin homogenate only once after inoculation with tumor homogenate but never after skin graft infection. Nevertheless, each skin passage resulted in skin heterogenization. Skin-heterogenizing virus persisted in the spleen of rejector mice in large amounts (titers 10^5 - 10^7) at least for 120 days after infecting grafting. The exchange skin grafting between rejector mice resulted in survival of transplants, though the skin from the same animals was rejected as usual by normal C57BL/6J recipients.

- 0145 TUMOR-INDUCED SKIN HETEROGENIZATION: III. IMMUNOLOGIC AND IMMUNOGENETIC MECHANISMS. (E.) Liozner, A. L. (USSR Min. Hlth., Moscow), G. J. Svet-Moldavsky and D. M. Mkheidze. *J Nat Cancer Inst* 45(3):485-494, 1970.

Mice from 4 different strains were inoculated with K-237 sarcoma, given skin grafts from tumor-bearing donors and injected with cell-free tumor homogenate to determine whether the strain specificity of skin heterogenizing virus obtained from K-237 sarcoma was determined by the generic constitution of the animals. Skin heterogenizing virus produced syngeneic skin rejection in C57BL/6J mice inoculated with any type of virus-containing materials, i.e., tumors, skin grafts, or cell-free tumor homogenates, but had no effect on BALB/c, CBA, C3HA, C3Hf, and T6T6 mice. Hybrid mice

(C57BL/6J X BALB/c) F_1 also resisted the heterogenizing action of the virus,¹ despite the fact that K-237 sarcoma always grew progressively in these hosts. Sensitivity to heterogenizing virus action seemed to be controlled by a recessive gene (or genes), and the C57BL/6J strain was probably homozygous in respect to the hypothetical gene. F_2 hybrid mice appeared to be somewhat sensitive to the heterogenizing action of the virus. Furthermore, some sensitive F_2 mice acquired the ability to infect C57BL/6J mice with skin heterogenizing virus as a result of skin grafting. Various immunosuppressive treatments such as whole-body γ -irradiation or cyclophosphamide not only delayed rejection of heterogenized skin but often abolished it. Far from being accelerated, the rejection of secondary grafts of C57BL/6J heterogenized skin was delayed 2-4 days. However, the second-set rejection of C57BL/6J heterogenized skin occurred after it was transplanted to (C57BL/6J X BALB/c) F_1 mice sensitized with similar grafts 3 weeks before. K-237 sarcoma cells failed to produce the new transplantation antigen present in skin cells, although the latter did not provide mature virus reproduction. These contradictory results may be due to the specificity of the viruses studied.

- 0146 A NEW VIRUS IN A SPONTANEOUS MAMMARY TUMOR OF A RHESUS MONKEY. (E.) Chopra, H. C. (John L. Smith Mem. Cancer Res., Charles Pfizer Co., Maywood, N. J.) and M. M. Mason. *Cancer Res* 30(8): 2081-2086, 1970.

Electron microscopy of a spontaneous mammary tumor developed by a female rhesus monkey was performed to investigate the ultrastructure and development of virus particles found in the tumor. Thin-section electron microscopy of the tumor tissue revealed 2 types of particles, an intracytoplasmic, electron-dense, ring-shaped particle measuring about 70 m μ in diameter and which occurred singly or in clusters; the density of the viral material was usually higher in the periphery, giving the particle a doughnut-shaped appearance. The other type was an extracellular particle with an outer unit membrane and a central dense nucleoid measuring about 110 m μ in diameter. The intracytoplasmic development and virus maturation by a process of budding at the level of the cell membrane was reconstructed from the electron micrographs. Although the identification of virus particles in monkey mammary carcinoma does not prove an etiological connection between the particles and the tumor, these particles distinctly resemble oncogenic RNA-type virus particles.

- 0147 IMMUNOLOGIC STUDIES OF HUMAN SARCOMAS: ADDITIONAL EVIDENCE SUGGESTING AN ASSOCIATED SARCOMA VIRUS. (E.) Eilber, F. R. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and D. L. Morton. *Cancer* 26(3):588-596, 1970.

The incidence of antibody to sarcoma-specific antigens prepared from human liposarcoma in the serum of patients with skeletal and soft tissue sarcoma was subjected to immunological study. Antigen prepared from SA-1 liposarcoma cells with titers of 1/8-1/64 reacted with 9 out of 10 sarcoma sera, while antigen with a titer 1/4 reacted with 1 out of 4

normal sera. The sarcoma-specific antigen was found in tissue culture cells derived from different histologic types of sarcoma but not in normal fibroblasts obtained from sarcoma patients, nor in cells from nonsarcomatous malignancies. Evidence for a relationship between the sarcoma antigen and an infectious agent included the observation that the antigen was common to different sarcomas, and the finding of a high incidence of antibody to the sarcoma antigen in close family members of the sarcoma patients. This relationship was confirmed by the demonstration that cell-free extracts derived from sarcoma tumors and filtered extracts from sarcomas in tissue cultures were capable of inducing the formation of the sarcoma-specific antigen in normal human cells. Evidently, there exists a filterable agent in human sarcomas capable of inducing a new sarcoma-specific antigen on normal human cells in tissue culture.

- 0148 RIBONUCLEIC ACID TRANSCRIPTASE ACTIVITY IN PURIFIED WOUND TUMOR VIRUS. (E.) Black, D. A. (Dept. Molec. Biol., U. California, Berkeley) and C. A. Knight. *J Virol* 6(2):194-198, 1970.

Wound tumor virus was isolated from infected sweet clover root tumors and subjected to standard polymerase activity assays in order to characterize an associated RNA transcriptase possessed by cells in this tumor. The product of transcriptase synthesis was found to be single-stranded RNA which annealed specifically to wound tumor viral RNA. Studies with RNA of cytoplasmic polyhedrosis virus, which also contains an associated RNA transcriptase, showed no common relationship between the two RNAs.

- 0149 VIRUS-LIKE PARTICLES IN LEUKEMIA CELLS OF A NEWBORN: ELECTRON MICROSCOPIC COMPARISON WITH HERPES SIMPLEX VIRUS. (Ger.) Lamper, F. (Child. Clin. U. Munich, Germany). *Klin Wschr* 48(12): 737-741, 1970.

Virus-like particles were detected in bone marrow leukemic cells of a 4-month-old female infant (post mortem) and compared to similar particles in a herpes simplex virus-infected cell culture. High resolution electron microscopy of these particles revealed 3 kinds of virus-like formations similar to those occurring at various maturation stages of the herpes simplex virus; these particles included vacuolated hexagonal naked "capsid" nucleocapsids (with an electron dense nucleus), and nucleus-like formations lacking the external capsid protection in portions where broken chromatin strands occurred. Nucleus-like formations were more frequent and capsid particles were less frequent in leukemic cell particles than in herpes virus simplex. The average capsid diameter of the leukemic cell virus particles was 1240 A and 1017 A in case of the herpes simplex virus capsid. The average nucleocapsid dry matter content, determined by quantitative electron microscopy, was 19.4×10^{-6} g for the leukemic cell particles and 7.6×10^{-6} g for the herpes simplex virus.

- 0150 LEUKEMIA IN FANCONI'S ANEMIA: CYTOGENETIC AND TUMOR VIRUS SUSCEPTIBILITY STUDIES. (E.) Dosik, H. (Maimonides Med. Ctr.,

Brooklyn, N.Y.), L. Y. Hsu, G. J. Todario, S. L. e, K. Hirschhorn, E. S. Selirio and A. A. Alter. *Proc Natl Acad Sci USA* 66(3):341-352, 1970.

family with 2 male children affected with Fanconi's anemia is described; 1 child developed acute myelomonocytic leukemia, an established concomitant of Fanconi's anemia, an inherited disorder characterized by multiple congenital abnormalities, chromosome anomalies and irreversible aplastic anemia. Chromosome preparations in both parents showed abnormalities, a previously unreported finding. Fibroblast cultures from both parents and one brother inoculated with simian virus 40 developed increased numbers of transformed colonies, compared with normal control cultures similarly inoculated. The presence of chromosome abnormalities and cellular susceptibility to oncogenic agents appear to be related to an increased risk of malignancy.

51 SEROEPIDEMIOLOGICAL STUDIES ON NASOPHARYNGEAL CARCINOMA BY FLUORESCENT ANTIBODY TECHNIQUES WITH CULTURED BURKITT LYMPHOMA CELL. (E.) Kawamura, A., Jr. (Inst. Med. Sci., U. Tokyo, Japan), M. Takada, A. Gotoh, K. Hamajima, T. Sanpe, T. Murata, Y. Ito, T. Takahashi, T. Yoshida, T. Hayama, S. M. Tu, C. H. Liu, C. S. Yang and C. H. Ng. *Gann* 61(1):55-71, 1970.

Examination of the sera of Burkitt lymphoma patients and nasopharyngeal carcinoma patients from Japan and Taiwan by a standardized method for detecting anti-Epstein-Barr virus antibodies showed that antibody titers of Chinese patients were higher than those of Japanese subjects. Furthermore, ridit analysis revealed that sera from infectious mononucleosis patients exhibited higher titers than those of leukemia, other cancers, and normal subjects; however, these titers were lower than those of the nasopharyngeal carcinoma and Burkitt lymphoma. Anti-EB virus titer higher than 1:640 was found in the sera of 85.7% of Burkitt lymphoma patients (7 cases), 91.1% of Chinese nasopharyngeal carcinoma patients (8 cases) in Taiwan, and 63.6% of Japanese nasopharyngeal carcinoma patients (11 cases), as compared with 15% in other malignancies and 5-15% in normal subjects. The sera of both nasopharyngeal carcinoma and Burkitt lymphoma patients appear to contain antibodies which possess the same or quite similar reactivity against the Epstein-Barr virus.

52 BURKITT'S TUMOR IN A TEN YEAR OLD BOY CONFIRMED HISTOLOGICALLY AND VIROLOGICALLY. (E.) Goetz, O. (Path. Inst. U. Munich, Germany), Lampert, P. Peller and K. Prechtel. *Munchen Med Wochenschr* 112(30):1373-1376, 1970.

The first case report of juvenile Burkitt's lymphoma in Germany, a 10-yr-old boy, is presented. The tumor was histologically assessed as a lymphosarcoma. Epstein-Barr viruses in tumor tissue culture and antibodies against Epstein-Barr virus, which developed during the course of the disease, were demonstrated by immunofluorescence.

0153 REACTIVITY OF RADIOIODINATED SERUM ANTIBODY FROM BURKITT'S LYMPHOMA AND NASOPHARYNGEAL CARCINOMA PATIENTS AGAINST CULTURE LINES DERIVED FROM BURKITT'S LYMPHOMA. (E.) Inoue, M. (Karolinska Inst., Stockholm, Sweden) and G. Klein. *Clin Exp Immun* 7(1):39-50, 1970.

Cells from Burkitt lymphoma lines, 1 line carrying Epstein-Barr virus and 1 line virus-free, were exposed to radioiodinated conjugates of the IgG serum immunoglobulin fractions of 2 Burkitt lymphoma and 1 African nasopharyngeal carcinoma patients. All 3 radioiodinated conjugates attached to live cells of an Epstein-Barr virus-carrying Burkitt line, but not to Epstein-Barr virus-free cells. A Swedish control serum did not block the binding of any of the 3 conjugates, whereas various unconjugated sera showed various degrees of blocking and cross-blocking. The blocking patterns were in good agreement with previous tests, performed with the same sera against their fluorescein conjugated derivatives. Antibody release tests, involving preincubation of live cells with one of the 3 conjugates, followed by incubation with unlabeled serum revealed a certain hierarchy between the 3 sera with regard to their ability to displace radioiodinated surface-coupled immunoglobulin. This ability could be related to the competitive behaviour of the same sera in the cross blocking tests. The results are believed to reflect differences in the affinity of the 3 antibodies due to differences in the duration of immunization in the 3 patients or to differences in affinity or fit to the surface antigens carried by the Epstein-Barr virus-carrying target cells.

0154 INFECTIOUS MONONUCLEOSIS FOLLOWED BY BURKITT'S TUMOR. (E.) Cohen, M. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), Y. Hirshaut, D. Stevens, E. W. Hull, J. W. Davis and P. P. Carbone. *Ann Intern Med* 73(4):591-593, 1970.

Studies were carried out to identify anti-Epstein-Barr virus antibody and Epstein-Barr virus antigen in the serum and bone marrow of a 17-year-old female patient who developed a tumor histologically and cytochemically identical to African Burkitt's tumor 16 months after having had infectious mononucleosis. Antibodies to Epstein-Barr virus were found in the patient. Although Epstein-Barr virus antigen could not be detected in any tissue taken directly from the patient, viral antigen was detected in buffy coat material after establishment in long-term culture. These studies indicate that there is either a different causal agent for these two diseases or that malignant transformation may have occurred during the acute phase of infectious mononucleosis, and the tumor became clinically recognizable 16 months later.

0155 INCIDENCE OF ANTIBODY TO EB VIRUS, HERPES SIMPLEX AND CYTOMEGALOVIRUS IN HODGKIN'S DISEASE. (E.) Aisenberg, A. C. (Massachusetts Gen. Hosp., Boston) and J. M. Goldman. *Cancer* 26(2):327-331, 1970.

The incidence of antibody against EB virus, herpes simplex and cytomegalovirus was measured in 57

patients with Hodgkin's disease and 54 age-matched control subjects. Serum specimens were tested for EB virus antibody using an indirect immunofluorescent technique and for herpes simplex and cytomegalovirus antibodies by a complement fixation method. No differences were seen in antibody titers to all three viral agents between patients with Hodgkin's disease and control subjects (50% with EB virus, 35% with herpes simplex and 7-8% with cytomegalovirus at age 15-34 yr and 30-40% higher for all three agents at age 35-70 yr). None of these viruses appear to play any part in the etiology of Hodgkin's disease. Furthermore, patients with lymphoproliferative disease do not seem to be any more susceptible to EB virus than the normal population.

- 0156 RELATIONSHIP OF EPSTEIN-BARR VIRUS-INDUCED MEMBRANE ANTIGENS IN LYMPHOID CELLS TO VIRAL ENVELOP ANTIGENS. (E.) Gerber, P. (Div. Biol. Standards, Natl. Inst. Hlth., Bethesda, Md.) and G. Goldstein. *J Immunol* 105(3):793-795, 1970.

The nature of immunofluorescent membrane antigens located on the surface of Epstein-Barr virus-infected lymphoma cells was investigated, and compared with antigens on cells derived from Burkitt's lymphoma. The sera from 20 patients with Burkitt's lymphoma or infectious mononucleosis, from normal human donors and chimpanzees were incubated with Raji (Epstein-Barr virus-free), HRIK-P3J from Burkitt's lymphoma (5-50% of cells with immunofluorescent Epstein-Barr virus antigen) or Epstein-Barr virus-transformed human lymphoid cell lines. The Epstein-Barr virus-transformed cells and the HRIK cells reacted only with Epstein-Barr virus-positive sera, 70-80% and 30-50%, resp. Immunofluorescent membrane antigens of Epstein-Barr virus-infected lymphoid cells from a normal donor and from a patient with Burkitt's lymphoma appear to be identical and to contain components of the viral envelop.

- 0157 VIRAL ANTIGEN, VIRUS PARTICLES, AND INFECTIVITY OF TISSUES FROM CHICKENS WITH MAREK'S DISEASE. (E.) Calnek, B. W. (New York State Vetr. Coll., Ithaca, N.Y.), T. Ubertini and H. K. Adldinger. *J Nat Cancer Inst* 45(2):341-351, 1970.

Tissue cultures from chickens which were exposed to Marek's disease herpes virus were subjected to fluorescent antibody and agar-gel precipitin tests and to electron microscopy to investigate their viral particle contents, their viral antigens, and their infectivity; some tissues were also assayed *in vitro* for cellular and cell-free materials. All samples of feather follicle epithelium were positive for antigen detectable by fluorescent antibody and agar-gel precipitin tests, contained large numbers of both naked and enveloped herpesvirus particles, and were the source of infectious, cell-free virus. The bursa of Fabricius, kidney, leukotic gonad, and nerve plexuses also contained fluorescent antibody-detectable antigen but not so consistently or extensively as did the feather follicle epithelium. All these tissues, except kidney, were found positive by the agar-gel precipitin test and were determined by electron microscopy to be infected, but nearly all virus

particles were naked and intranuclear. Infectivity was cell-associated, as shown by *in vitro* virus assays.

- 0158 MAREK'S DISEASE HERPESVIRUS IN PERIPHERAL NERVE LESIONS. (E.) Ubertini, T. (New York State Vetr. Coll., Ithaca) and B. W. Calnek. *J Nat Cancer Inst* 45(3):507-514, 1970.

A chicken experimentally exposed by continuous contact exposure to chickens infected with Marek's disease herpesvirus was autopsied at 34 days with special attention to its sciatic and brachial nerve plexuses. Electron microscopy revealed ultrastructural lesions in both nerves indicating activation of Schwann cells and degeneration of some lymphoid cell elements. Neuronal damage also was observed. The brachial plexus contained Schwann cells, immature lymphoid cells, and degenerated lymphoblastoid cells (Marek's disease cells) with characteristic intranuclear herpesvirus particles. Similar cells in the sciatic plexus appeared to contain no virus particles.

- 0159 PLAQUE TYPES AND CELL-FREE VIRUS FROM TISSUE CULTURES INFECTED WITH CAL-1 STRAIN OF HERPESVIRUS ASSOCIATED WITH MAREK'S DISEASE. (E.) Mikami, T. (Sch. Vetr. Med., U. California, Davis) and R. A. Bankowski. *J Nat Cancer Inst* 45(2):319-333, 1970.

Two distinct plaque types produced with the Cal-1 strain of Marek's disease virus in chicken kidney cell cultures, and the differences in the quantity of free infectious virus produced by each were investigated. The smaller type 1 plaque, normally observed on primary isolation of the agent from chickens infected with Marek's disease, was replaced by a larger type 2 plaque by the fourteenth serial passage. The type 2 plaques grew more rapidly. By the 5th-6th day the plaques were 1.0-2.5 mm in diameter and characterized by pronounced cytoplasmic vacuolation of the affected cells, followed by lysis. Intranuclear inclusions were more frequent in cells of the type 2 plaques than in cells of the type 1 plaques. The addition of 10% dimethylsulfoxide and 10% fetal calf serum to Eagle's basal medium resulted in a marked sparing effect as demonstrated by recovery of infectious virus from chick kidney cell cultures after freezing and thawing, sonic disruption, centrifugation, or vibration. Type 2 plaque-producing virus was recovered from filtrates of supernatants of cell cultures as well as chick kidney cell cultures disrupted by freezing and thawing and passed through a 1.2 μ Millipore membrane. Although fusion of cells appeared to increase recovery of virus which produced the type 1 and type 2 plaques, the yield of Marek's disease virus was not significantly increased in chick kidney cell cultures by the addition of inactivated and concentrated Sendai virus.

- 0160 SUSCEPTIBILITY TO AN AVIAN LEUKOSIS-SARCOMA VIRUS: CLOSE ASSOCIATION WITH AN ERYTHROCYTE ISOANTIGEN. (E.) Crittenden, L. B.

ric. Res. Serv., Beltsville, Md.), W. E. Briles
H. A. Stone. *Science* 169(3952):1324-1325, 1970.

geny embryos of an inbred RPRL strain of chickens
ch is known to be segregating at the gene loci
controlling susceptibility to avian leukosis-sarcoma
us were tested for susceptibility by inoculation
h Rous sarcoma virus and their erythrocytes were
ted for antigens. A dominant gene for suscepti-
ity to infection by avian leukosis-sarcoma virus
shown to be associated with the presence of an
throcyte isoantigen. An isoantigen and a cell
brane receptor for an oncogenic virus may both
controlled by the same gene; alternatively,
sely linked genes or a complex gene locus may
trol both the antigen and viral susceptibility.

1 PERIPHERAL NERVE LESIONS SIMILAR TO THOSE
OF MAREK'S DISEASE IN CHICKENS INOCULATED
H RETICULOENDOTHELIOSIS VIRUS. (E.) Witter, R. L.
gional Poultry Res. Lab., East Lansing, Mich.),
G. Purchase and G. H. Burgoyne. *J Nat Cancer Inst*
3):567-577, 1970.

ite leghorn chickens inoculated with reticuloendo-
liosis virus developed gross lymphoproliferative
ral lesions similar to lesions associated with
ek's disease. Induction of these nerve lesions
reticuloendotheliosis virus stocks from 4 differ-
sources and substantial cross neutralization be-
en neurotropic and viscerotropic reticuloendotel-
is virus stocks were evidence that the lesions
e specific for reticuloendotheliosis virus. Nerve
ions induced by the virus were characterized by
ndant plasma cells, but they could not always be
ferentiated from lesions of Marek's disease. How-
r, the absence of contact spread and the high sus-
tibility of line 6 chickens were some obvious
characteristics distinguishing this syndrome from
t of Marek's disease. No antibody against reticu-
ndotheliosis virus was detected in 5 commercial
cks of chickens with extensive Marek's disease
ses, and evidence was lacking that reticuloendo-
liosis virus infection was of economic importance.

2 LACK OF EFFECT OF BURSECTOMY ON MAREK'S
DISEASE. (E.) Payne, L. N. (Houghton
ltry Res. Station, Huntingdon, England) and M.
nie. *J Nat Cancer Inst* 45(2):387-397, 1970.

born chicks of a Rhode Island Red strain highly
ceptible to Marek's disease and in which the
ease had been induced by Marek's disease herpes-
e virus were bursectomized, with or without total
y X-irradiation, to determine whether this treat-
t would reduce the mortality from Marek's disease.
mortality in infected sham-operated chickens
h and without X-irradiation was 93% and 80%,
p.; the mortality in infected bursectomized chick-
with and without X-irradiation was 100% and 93%,
p. The production of Marek's disease in chickens
h varying degrees of impairment of the bursal
phoid system, including some chickens which ap-
ently lacked antibodies, immunoglobulins, ger-
al centers, and plasma cells, suggested that the
hogenesis of the disease did not depend on the
sa and bursa-dependent lymphoid tissues.

0163 METHODS FOR THE DETECTION OF VIRAL ANTIGEN
AND ANTIBODY TO A FELINE LEUKEMIA VIRUS:
A PRELIMINARY REPORT. (E.) Sibal, L. R. (Natl. Cancer
Inst., Natl. Inst. Hlth., Bethesda, Md.), M. A. Fink,
E. J. Plata, B. E. Kohler, F. Noronha and K.M. Lee.
J Nat Cancer Inst 45(3):607-612, 1970.

Sheep redblood cells coated with virus extracts from
cultured thymus cells from a cat with experimental
leukemia and goat serum from immunized animals were
used in passive hemagglutination-inhibition and micro-
immunodiffusion tests in order to detect and measure
feline leukemia virus antigens in tumor and tissue
extracts. Various tissues from 12 of 13 cats with
spontaneous leukemia (lymphosarcoma) contained feline
leukemia virus antigen; normal cat tissues did not.
The predominant antigen detected in these tests was
an inner component of the virion. None of 20 cat
sera showed antibody to this antigen. However, in
hemagglutination and focus reduction tests antibodies
to an outer coat antigen of the virus were observed
in the serum of some normal and leukemic cats.

0164 FELINE LEUKEMIA VIRUS: PURIFICATION FROM
TISSUE CULTURE FLUIDS. (E.) Burger, C. L.
(St. U. New York Upstate Med. Ctr., Syracuse) and
F. Noronha. *J Nat Cancer Inst* 45(3):499-506, 1970.

A method for the isolation and concentration of large
amounts of leukemia virus from a lymphoid cell line
grown in suspended cell culture, derived from kit-
ten F-422, is reported. After an initial concentra-
tion of tissue culture supernatant by continuous-
flow centrifugation, isopycnic separation was done
on a step gradient of 10, 30 and 60% sucrose
(87,000 x g for 3 hr). The portion showing the
greatest viral concentration appeared at the 1.20
g/cc density level. Each 1.5 l of supernatant from
the cell culture contained approximately 100 µg
nucleic acid in the bands containing the virus.
Reovirus was a contaminant in some cultures used
for separation of the leukemia virus, but the den-
sity of this virus was 1.3 g/cc and easily separated.

0165 ANTIGENIC ANALYSIS OF L STRAIN CELLS: A
NEW MURINE LEUKEMIA-ASSOCIATED ANTIGEN,
"L". (E.) LeClerc, J. C. (Hosp. St. Louis, Paris,
France), J. P. Levy, B. Varet, S. Oppenheim and A.
Senik. *Cancer Res* 30(7):2073-2079, 1970.

Serological analysis of a non-leukemic mouse tissue cul-
ture cell line of the L strain and the induction of
transplantation immunity were performed; 3 antigens as-
sociated with murine leukemia virus were observed in
these healthy cells. The antigens observed included
the group-specific antigen of murine leukemia virus-
es and an antigen common to Friend, Moloney, Rauscher,
and Graffi leukemias. The group-specific and Friend,
Moloney, Rauscher and Graffi antigens are probably
related to the nonleukemogenic type C virus present
in L Cells. A new antigen, L antigen, which is also
present in various virus-induced leukemias of several
strains and in the dimethylbenzanthracene-induced
leukemia was also observed. L antigen was shown to
be different from other already described murine leu-
kemia antigens. No tumor rejection of L+ tumors was

observed in hyperimmune mice despite the presence of cytotoxic antibodies in the blood. Enhancement of tumor growth was frequently observed in this situation. The role of the L antigen in tumor rejection is unclear; it may be that immunization against the L antigen leads to immunological enhancement rather than rejection.

- 0166 MURINE MYELOPROLIFERATIVE VIRUS IN CELL CULTURE. (E.) Soule, H. D. (Michigan Cancer Found., Detroit) and W. J. Arnold. *J Nat Cancer Inst* 45(2):253-262, 1970.

A cell culture system, MCF-6, which was able to maintain for over 2 yr a virulent leukemogenic virus has been isolated from BALB/c mice. The primary culture from which the stable cell line was derived was initiated from pooled lymph nodes combined with the thymus and spleen from a BALB/c mouse with advanced leukemia from inoculation with DICR-5 cell-free supernatant. Cells or supernatant from MCF-6 produced myeloproliferative disorders when injected into neonatal BALB/c mice (but not in older animals) with mortalities of 70-90% after mean latencies of onset of between 100-150 days. Electron micrographs of MCF-6 supernatant showed particles resembling murine leukemia-inducing viruses. Cells from the culture did not transplant, but spleen cells from infected mice were transplantable and produced malignancy in 92% of young adult animals inoculated, with a mean latency of 31 days.

- 0167 LYMPHOSARCOMA: VIRUS-INDUCED THYMIC-INDEPENDENT DISEASE IN MICE. (E.) Abelson, H. T. (Child. Hosp. Med. Ctr., Boston, Mass) and L. S. Rabstein. *Cancer Res* 30(8):2213-2222, 1970.

A lymphosarcoma virus was isolated from a tumor which had developed in a mouse treated with high doses of prednisolone (0.05 mg twice a week for 93 days) and inoculated with Moloney MLV³ leukemia virus at 28 days of age. Mice and rats infected with this lymphosarcoma virus within 36 hr after birth developed solid lymphoid tumors after a latent period of 26-32 days. A unique feature of the induced condition was the lack of thymic involvement; thymic-independent tumor induction distinguishes this virus from the other experimental murine lymphoid leukemia viruses. Massive meningeal tumors, a myelocytic leukemoid reaction, and the absence of evidence of a disseminated leukemia were features of this disease.

- 0168 PROLIFERATIVE ACTIVITY IN THE LYMPHATIC TISSUES OF GERM-FREE NEW ZEALAND BLACK MICE. (E.) Denman, A. M. (Canadian Red Cross Mem. Hosp., Taplow, Berkshire, England) and E. J. Denman. *Int J Cancer* 6(1):108-122, 1970.

The incorporation of ³H-thymidine into the DNA of lymphoid cells in the thymus, spleen, lymph nodes and bone marrow of germ-free New Zealand Black mice of differing ages was measured quantitatively and by autoradiography to compare the proliferation of lymphoid cells at these sites in germ-free mice and conventional mice. Lymphoid cell proliferation,

particularly in splenic germinal centers, was the earliest abnormality noted in germ-free NZB mice and was equal in intensity to that observed in the conventional control strain. With the onset of autoimmune disease, reticulum cell and "blast" cell proliferation was qualitatively similar in the spleens of germ-free and conventional NZB mice, the former cell type predominating in the oldest mice examined. No evidence was obtained of any primary defect in lymphocytopoiesis in the thymus or other lymphatic tissues of the NZB strain. The onset of autoimmune disease in these mice may be preceded by lymphoproliferative changes; no differences were observed between germ-free and conventional animals or between males and females.

- 0169 INHERITANCE OF SUSCEPTIBILITY TO FRIEND MOUSE LEUKEMIA VIRUS: VII. ESTABLISHMENT OF A RESISTANT STRAIN. (E.) Odaka, T. (Inst. Med. Sci., Takanawa, Tokyo, Japan). *Int J Cancer* 6(1):18-23, 1970.

An attempt was made to place the gene for resistance to Friend leukemia virus in C57BL/6 mice, gene Fv^r, into the genetic background of susceptible mice of the DDD strain; the attempt was inspired by the finding that a single major autosomal locus controls susceptibility to Friend leukemia virus in mice. Using the cross-intercross system, the mice with Fv^r/Fv^r genotype were selected by progeny test at each even-numbered generation. During successive matings, the effect of gene Fv^r was not diluted out, and progeny were almost always obtained as expected from the single gene hypothesis. After 5 to 6 cycles of cross-intercross, brother-sister mating was done between the mice with Fv^r/Fv^r genotype. The progeny are homozygous for gene Fv^r and could be assumed to be congenic with DDD mice except for susceptibility to Friend leukemia virus. Locus Fv^r may be involved in cell proliferation rather than in virus multiplication, for, in mice of the new strain, the virus did not induce typical splenic megaly, but multiplied to a considerable level.

- 0170 ANTIGENIC MODIFICATION OF RAT TUMOR CELLS ARTIFICIALLY INFECTED WITH FRIEND VIRUS IN THE PRIMARY AUTOCHTHONOUS HOST. (E.) Sendo, F. (Hokkaido U. Sch. Med., Japan), H. Kaji, H. Saito and H. Kobayashi. *Gann* 61(3):223-226, 1970.

Tumors induced in rats by 3-methylcholanthrene were excised and artificially infected with Friend virus; these infected tumor cells when transplanted back into the autochthonous host did not grow well and later regressed spontaneously. However, transplanted non-infected primary tumor cells grew well and killed the autochthonous hosts, and infected primary tumor cells transplanted into Friend virus-tolerant rats grew well and killed the hosts. The virus infection appears to have modified the membranous antigens of the tumor cells to make them immunologically foreign to the autochthonous host.

- 0171 CHARACTERIZATION OF A RAPIDLY GROWING AKR LYMPHOBLASTIC CELL LINE MAINTAINING GROSS ANTIGENS AND VIRAL REPLICATION. (E.) Woods, W. A. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda,

Id.), N. A. Wivel, J. G. Massicot and M. A. Chirigos. *Cancer Res* 30(8):2147-2155, 1970.

Morphological and antigenic characteristics of a tissue culture system (AKR-A) established from an AKR ascitic cell line (from a spontaneous lymphoma found in a 9-month AKR mouse) are presented. The lymphoblastic cells (major cell type) are separated from the giant cells in primary cultures by utilizing the different growth rates, and the AKR-A cells can be maintained in the logarithmic phase of growth for 7 months. Antigen which was specific for GLV-infected cells, cellular antigen for anti-GLV serum, and the release of infectious GLV into the tissue culture fluid were observed in the AKR-A cells. *In vitro* passage of the AKR-A cells did not attenuate their tumor-producing capacity with the LD₅₀ in the male AKR mice remaining constant at 40 cells i.v.; the median survival time after 100 LD₅₀ was 11 days for AKR-A cells compared to 10 days for the AKR-ascites cells.

0172 GENETIC BASIS FOR SUSCEPTIBILITY TO LEUKEMIA INDUCTION BY AKR THYMUS GRAFTS. (E.) Takakuki, K. (Sch. Med., Mie Prefect. U., Japan). *Cancer* 61(1):85-87, 1970.

The influence of genetic constitution on the induction of leukemia by thymus grafts from high-leukemia strain AKR mice was investigated in F₁ hybrids of AKR and C3Hf or C57BL mice; (C3Hf x AKR)F₁ were homozygous for H-2^k and (C57BL x AKR)F₁ were heterozygous for H-2^k (H-2^{kb}). The incidence of leukemia was 17/22 in AKR mice, 23/34 in (C3Hf x AKR)F₁ mice and 0/22 in (C57BL x AKR)F₁ mice 104-180 days after AKR thymus grafting. None of the hybrid mice grafted with C3Hf or C57BL thymus of the same age developed leukemia. The leukemogenic capability of AKR thymus (Gross virus) and strain susceptibility appear to be influenced by genetic control.

0173 INFLUENCE OF PREDNISOLONE ON MOLONEY LEUKEMOGENIC VIRUS IN BALB/c MICE. (E.) Belson, H. T. (Child. Hosp. Med. Ctr., Boston, Mass.) and L. S. Rabstein. *Cancer Res* 30(8):2208-2212, 1970.

The effects of long term administration of prednisolone acetate (0.025 or 0.05 mg s.c. twice a week starting less than 24 hr after birth) on BALB/c mice response to Moloney leukemia virus were investigated. Lymphocytic leukemia developed in 0/83 mice given the high dose of prednisolone plus virus, in 60/78 mice given the low dose of prednisolone plus virus and in 83/92 mice inoculated with the virus alone. Significant numbers (at least 10%) of the infected prednisolone-treated mice developed solid lymphosarcomas or granulocytic leukemia compared to 1 occurrence of lymphosarcoma and no granulocytic leukemia in mice receiving virus alone; no tumors or leukemia were found in control animals. Inoculation of mice treated with the high dose prednisolone at 7 or 14 days after treatment was begun resulted in a 50% delay in onset of lymphocytic leukemia. The alteration in disease response may be attributed to a prednisolone-induced simulated thymectomy.

0174 HISTOPROLIFERATIVE EFFECT OF RAUSCHER LEUKEMIA VIRUS ON LYMPHATIC TISSUE. II. ANTIGEN-STIMULATED GERMFREE AND CONVENTIONAL BALB/c MICE. (E.) Hanna, M. G., Jr. (Oak Ridge Natl. Lab., Tenn.), H. E. Walburg, Jr., R. L. Tyndall and M. J. Snodgrass. *Proc Soc Exp Biol Med* 134(4):1132-1141, 1970.

Germfree mice received an i.p. injection of 1 ml of 1% sterile sheep erythrocytes followed by an infective i.p. injection of 0.5 ml Rauscher leukemia virus in order to establish a test system for studying the role of nonthymus-dependent and thymus-dependent lymphoid tissue in Rauscher leukemia virus infection; the leading hypothesis was that the splenomegaly associated with Rauscher disease in a germfree population would be enhanced by the establishment of active germinal centers in the nonthymus-dependent region of the lymphatic nodules of mice immunized with sheep erythrocytes. Ten days after viral infection, the sheep erythrocyte-pretreated mice exhibited 65% increase in spleen wt over the normal germfree mice. The retention by spleens of ¹²⁵I-iododeoxyuridine was also tested, with the result that sheep erythrocyte-immunized mice retained markedly more ¹²⁵I-iododeoxyuridine than unimmunized mice. Apparently, antigen-retaining reticular cells and immunoblasts of lymphatic tissue germinal centers play a necessary part in early lymphoblastosis and subsequent splenomegaly of Rauscher disease. Rauscher preparation seems, in addition, to have a differential effect on thymus and nonthymus-dependent regions of the lymphatic tissue, as indicated by morphologic results.

0175 TYPE-C PARTICLES IN HUMAN TISSUES: II. ELECTRON MICROSCOPIC STUDY OF EMBRYONIC CULTURES INFECTED WITH A MURINE LEUKEMIA VIRUS. (E.) Chandra, S. (John L. Smith Mem. Cancer Res., Charles Pfizer & Co., Maywood, N. J.), R. Stephens, B. S. Wright, W. Korol, I. Zelljadt and E. M. Jensen. *Int J Cancer* 6(1):46-55, 1970.

Human embryonic cultures were infected with the carcinogenic Rauscher murine leukemia virus to investigate the synthesis of type C virus particles by these cultures. Type C particles have the characteristic morphology of the murine leukemia viruses. In some cultures, type-C particles were also observed budding into the cisternae of rough endoplasmic reticulum of a few cells. Virus particles in the vicinity of such cells were of the immature type. In contrast, particles in the vicinity of those cells which did not synthesize intracisternal type-C particle were of the mature type. It is not clear whether or not the intracisternal particles and the mature extracellular type-C particles have the same morphology.

0176 DEOXYCHOLATE RELEASES RNA FROM RAUSCHER MURINE LEUKEMIA VIRUS. (E.) Smith, J. W. (St. Jude's Child. Res. Hosp., Memphis, Tenn.) and D. W. Kingsbury. *Proc Soc Exp Biol Med* 134(4):1039-1042, 1970.

A representative oncogenic RNA virus, Rauscher murine leukemia virus, was disrupted with deoxycholate and examined for subviral entities or nucleocapsids.

Deoxycholate treatment released RNA which sedimented at the same rate as the free RNA released by sodium dodecyl sulfate, a strongly ionic detergent. In virus which had been labeled in culture with ^{14}C -amino acids and then treated with deoxycholate, very little of the label was recovered with the viral RNA, indicating that little viral protein was associated with the released viral RNA. This RNA was completely sensitive to pancreatic ribonuclease, which indicates that the Rauscher murine leukemia virus probably does not reside in a subviral structure which resembles nucleocapsids isolated from nononcogenic enveloped RNA viruses.

- 0177 LOSS OF T ANTIGEN BY CELLS DERIVED FROM A HAMSTER TUMOR INDUCED BY ADENOVIRUS TYPE 12. (E.) Vasconcelos-Costa, J. (Gulberkian Inst. Sci., Oeiras, Portugal). *Int J Cancer* 6(1):24-30, 1970.

The effects of freezing on the morphology, growth, tumorigenicity, and tumor antigen synthesis of cells from an adenovirus type 12-induced hamster tumor were tested by freezing cells cultured from a second transplantation of such a tumor in liquid nitrogen and 10% dimethylsulfoxide. Subsequently these cells were cultured in the same conditions as the parent cells, where it was observed that they kept the morphological and growth characteristics and the tumorigenicity of the cells from the former culture. The synthesis of surface antigen was maintained but tumor antigen and tumor-specific transplantation antigen were not detectable. It cannot be conclusively stated that the freezing treatment or dimethylsulfoxide action was the cause of tumor antigen loss, although these are the most plausible explanations.

- 0178 INDUCTION OF INTERFERON IN CHICK CELLS BY ADENOVIRUSES OF DIFFERENT ORIGIN. (E.) Beladi, I. (U. Med. Sch. Szeged, Hungary), M. Bakay, R. Pusztai and G. Hidasi. *J Gen Virol* 8(2):143-144, 1970.

The induction of interferon in primary chick embryo fibroblast cells by canine hepatitis virus, bovine adenovirus, simian adenovirus and an avian virus was investigated, and compared to the interferon production by a human adenovirus. All adenoviruses studied induced interferon in chick cells, and the interferon-inducing ability of different adenoviruses was not dependent on the infective dose administered. Trypsin treatment did not reduce the infectivity of any of the adenoviruses. However, human and simian adenoviruses were not able to induce interferon after trypsin treatment, although trypsin-treated avian, bovine and canine types continued to induce interferon.

- 0179 ADENOVIRUS-ASSOCIATED VIRUSES: ENHANCEMENT BY HUMAN HERPESVIRUSES. (E.) Blacklow, N. R. (Natl. Inst. Allerg. Infect. Dis., Natl. Inst. Hlth., Bethesda, Md.), M. D. Hoggan and M. S. McClanahan. *Proc Soc Exp Biol Med* 134(4):952-954, 1970.

Studies were performed to examine any possible relationship between adenovirus-associated viruses

(AAV) and other human herpesviruses, Epstein-Barr virus, cytomegalovirus and varicella-zoster virus. Stock pools of AAV type 1(H) and AAV type 3(H) were heated for 15 min at 56°C to eliminate infectious adenovirus, and incubated with each of the other viruses in HEP-2 and WI38 cell cultures. All herpesviruses helped AAV1 to produce immunofluorescence antigen, but they were unable to elicit either the production of detectable AAV1 complement-fixing antigen or physical particles as viewed by electron microscopy. AAV1 immunofluorescence antigen was propagated only with adenovirus 7, but not with the other herpesviruses even at the second passage level, indicating that infectious AAV1 was produced only in the presence of adenovirus 7.

- 0180 DEMONSTRATION OF TWO GROUP-SPECIFIC TSTAS IN ADENOVIRUS-INDUCED TUMORS. (E.) Ankerst, J. (Dept. Med. Microbiol., U. Lund, Sweden) and H. O. Sjogren. *Int J Cancer* 6(1):84-94, 1970.

Mice and rats were infected with human adenovirus types of groups A, B, C and D (types 1, 3, 4, 5, 7, 12, 18 and 31) to determine whether infection would induce immunity to the tumor specific transplantation antigen. Colony inhibition tests were used to detect immunity. No immunity was induced by adenovirus of groups A and B (types 3, 7, 12, 18 and 31) against an adenovirus type 1 tumor; however, 2 adenovirus types belonging to group C (types 1 and 5) were similarly tested and found to induce a clear-cut immunity to the adenovirus type 1 tumor but not to tumors induced by adenovirus of groups A and B. The only tested virus type of group D (type 4) did not induce any clear-cut immunity to either adenovirus 12 tumors or the adenovirus 1 tumor. Immunization of rats with rat adenovirus 12 tumor cells induced a cellular immunity to adenovirus 12 mouse tumor cells but not to a mouse polyoma tumor; adenovirus 1 rat tumor cells induced no such immunity. Immunization of rats with syngenic adenovirus 12 tumor cells induced a cellular immunity to adenovirus 12 rat and mouse tumors and an adenovirus 7 hamster tumor, but not to an adenovirus 1 rat tumor or BHK-C13 control hamster cells. These results seem to be consistent with the existence of a common tumor specific transplantation antigen induced by types 7 and 12 and a different tumor specific transplantation antigen induced by type 5 virus. Apparently, the highly oncogenic group A and the weakly oncogenic group B adenovirus types all induce a common tumor specific transplantation antigen; and another tumor specific transplantation antigen is induced by the group C viruses, while no evidence has been obtained to indicate that group D virus types induce any tumor specific transplantation antigens.

- 0181 FATE OF ADENOVIRUS TYPES 2 AND 12 IN INFECTED SERIAL CULTURES OF NON-PRIMATE ORIGIN. (E.) Winters, D. (Natl. Inst. Med. Res., London, England) and N. Khoobyarian. *J Gen Virol* 8(2):95-104, 1970.

Rabbit heart fibroblast cells were inoculated with adenovirus, types 2 or 12, to investigate the development of infectious virus and antigens in the cultures. The formation of infectious virus and anti-

ns decreased with each successive passage of cells until the virus was ultimately eliminated from the cultures. These cultures then emerged into a new phase in which some virus-induced proteins were present in at least a small proportion of cells. Adenovirus 2 fiber antigen persisted throughout the 15th subculture, whereas adenovirus 12 early tumor and late fiber antigens were carried throughout the 30th subculture over a period of 600 days. Virus-free but antigen-containing cells may therefore have possessed at least a portion of the virus genome. Shortly after the disappearance of virus, distinct multilayered foci of cells emerged in both lines; but only in the adenovirus 12 line did this phenomenon appear as a characteristic feature of the culture.

82 TUMOR INDUCTION IN HAMSTERS WITH AN AVIAN ADENOVIRUS (CELO): BRIEF REPORT. (E.) Mancini, L. O. (Union Carbide Res. Inst., Tarrytown, N. Y.), J. Anderson, V. Jasty and V. J. Jasty. *Arch Ges Virusforsch* 30(2-3):261-262, 1970.

Partially purified chicken-embryo-lethal-orphan virus, either untreated, irradiated, or mixed with 10% chicken embryo extract, tumor extract or 10% sucrose was injected into hamsters intradermally, intracranially or subcutaneously to determine if the treatment or the method of inoculation could affect the time and percentage of tumor induction. Hamsters inoculated intracranially with the virus alone or with chicken embryo extract produced epimomas in 33% and 22% of the animals, resp., in 14 weeks; subcutaneous inoculation with virus and embryo extract resulted in fibrosarcoma formation in 42% of the animals in 9 weeks. The other procedures and mixtures produced no tumors or induced tumors at a low rate and over a longer time interval.

83 THE SPECIFICITY OF ADENOVIRUS-HUMAN SERUM INHIBITOR INTERACTION. (E.) Shortridge, F. (U. Coll. Hosp. Med. Sch., London, England). *Arch Ges Virusforsch* 30(2-3):238-244, 1970.

Electrostatically separated surface components of hemagglutinating adenovirus type 5 and the soluble antigens of this virus were reacted with a known hemagglutinating virus inhibitor to study the specificity of the ensuing interaction. The nonspecific inhibitor of adenovirus hemagglutination combined with hexons (soluble and viral) as well as with the hemagglutinating entities to produce flocculation. Therefore the hemagglutination inhibition test was best performed using either penton or fiber antigen as indicator; the fiber was preferable because of its stability. The inhibitor appeared to combine specifically with the hexons proper; the adjacent hexons and/or peripentons may be responsible for attachment of virus to the host cell. These results underline the importance of the use of serum inhibitors in the elucidation of the nature of the viral surface and the relationship of that surface to red blood cell and host cell systems. Chemical identification of the active groupings involved may elucidate the fundamentals of the infective process.

0184 THE RESPONSE OF BHK 21 CELLS TO INFECTION WITH TYPE 12 ADENOVIRUS: III. TRANSFORMATION AND RESTRICTED REPLICATION OF SUPERINFECTING TYPE 2 ADENOVIRUS. (E.) Strohl, W. A. (Rutgers Med. Sch., New Brunswick, N. J.), H. Rouse, K. Teets and R. W. Schlesinger. *Arch Ges Virusforsch* 31(1-2):93-112, 1970.

A clonal line of hamster cells (BHK 21) was subjected to high multiplicity infection with adenovirus (type 12) to investigate the transformation response of the cells; a transformation rate of approximately 2×10^{-5} per initially infected cell was observed. A study of the fate of the abortively infected cells revealed, however, that only a small fraction survived the infection and initiated growth of a colony. Of these rare surviving colonies, nearly half contained transformed cells. Of 3 cell sublines tested, 1 yielded transformed cells only from colonies growing in soft agar suspension, a second yielded transformants only as foci in monolayers, while the third did not yield detectable transformants by either method. The adenovirus-transformed cells were distinguished from the parental cells by the following characteristics: a marked morphological alteration; the synthesis of adenovirus tumor antigen; growth to high cell density in the presence of a low concentration of serum; induction, in hamsters, of tumors identical to those induced by inoculation of type 12 virus; and restriction in the ability to support the multiplication of type 2 adenovirus (Ad2). The latter property may be due to blockage of a step late in the adenovirus replicative cycle, since 88% of the cells, which synthesized adenovirus type 2-specific structural antigens did not yield infectious virus. A similar shift from a productive to a largely abortive response to adenovirus 2 was seen in cells simultaneously infected with adenovirus 12 and adenovirus 2. Apparently, an association exists between continued activity of part of the adenovirus type 12 genome and the restriction of adenovirus type 2 replication in adenovirus type 12-transformed cells.

0185 SARCOMAS AFTER INOCULATION OF NEWBORN HAMSTERS WITH *HERPES VIRUS HOMINIS* TYPE 2 STRAINS. (E.) Nahmias, A. J. (Emory U. Sch. Med., Atlanta, Ga.), Z. M. Naib, W. E. Josey, F. A. Murphy and C. F. Luce. *Proc Soc Exp Biol Med* 134(4):1065-1069, 1970.

Doses greater than 10^3 TCD₅₀ of *Herpes virus hominis*, type 1 or 2, injected into newborn hamsters caused nearly 100% mortality, while lesser doses produced sarcomas 5-28 months after inoculation of 5 different virus strains. None of the animals inoculated with *Herpes virus hominis* type 1 strains developed tumors, and one newborn hamster inoculated intrathoracically with Eagle's MEM developed a well-differentiated cheek-pouch fibrosarcoma. Eight of 9 tumors with *Herpes virus hominis* type 2 strains occurred at or close to the site of inoculation and the histological characteristics of some of these tumors differed from those associated with other viral-induced hamster sarcomas. There is no clear-cut evidence of a relationship between *Herpes virus hominis* and the tumors, although C-type particles were observed by electron microscopy in 2 or 3 tumors.

- 0186 ANTIBODY TO GENITAL HERPES SIMPLEX VIRUS: ASSOCIATION WITH CERVICAL ATYPIA AND CARCINOMA *IN SITU*. (E.) Aurelian, L. (Johns Hopkins Sch. Med., Baltimore, Md.), I. Royston and H. J. Davis. *J Nat Cancer Inst* 45(3):455-464, 1970.

The prevalence of antibodies to the genital variant of herpes simplex virus (HSV-2) in sera of 36 women with atypia and of 32 women with carcinoma *in situ* (30-35 yr average age) and in women with invasive carcinoma (53 yr average age) was compared to a matched control population. The occurrence of antibody to HSV-2 was 100% in patients with invasive carcinoma and carcinoma *in situ* and 95% in women with cervical atypia, but only 50% in the control population. The data support the hypothesis that genital herpes simplex virus may be responsible for squamous neoplasia in the human cervix. Detection of viral components in neoplastic cells is needed for further substantiation of the possible relationship of HSV-2 and cervical carcinoma.

- 0187 HERPESVIRUS TYPE 2 INFECTION AND CARCINOMA OF THE CERVIX. (E.) Sprecher-Goldberger, S. (Brabant Pasteur Inst., Brussels, Belgium), L. Thiry, J. P. Cattoor, R. Hooghe and J. Pestiau. *Lancet* 2(7666):266, 1970.

The association of genital herpes simplex virus type-2 infection with cervical carcinoma in Belgium was demonstrated by vaginal exfoliative cytology and by the observation of specific neutralizing antibodies to herpesvirus type-2 in patients with cervical carcinoma. Serum samples were obtained from patients with invasive carcinoma of the cervix and compared with samples from patients without cervical carcinoma. The results confirm that women with invasive carcinoma of the cervix have a high incidence (83%) of antibodies to herpes virus type-2. Herpetic infection was quite evidently localized among cervical cancer patients, for all patients studied had been exposed to the same risk of herpes infection.

- 0188 INHIBITION OF HERPES VIRUS-INDUCED GIANT CELL FORMATION BY COMPOUND 48/80. (Ger.) Falke, D. (Inst. Med. Microbiol., Johannes Gutenberg U., Mainz, Germany) and G. F. Kahl. *Arch Ges Virusforsch* 30(4):353-366, 1970.

Herpes virus-induced giant cell formation in a rabbit kidney cell culture was inhibited by the histamine releasing compound 48/80. Vacuolization of the cell cytoplasm occurred 6 hr after compound 48/80 administration; these vacuoli appeared to be a result of lysosomal activation which was confirmed by acid phosphatase determinations. Comparison of structural analogs of the monomer of compound 48/80 and Resochin in terms of inhibition effects of giant cell formation, lysosomal activation and histamine release revealed that Resochin activated the lysosomes at 1 µg/ml and blocked giant cell formation at a concentration of 50 µg/ml, producing no histamine releasing effects. Compound 48/80 released histamine at a concentration of 0.1 µg/ml, blocked giant cell formation at 10 µg/ml concentration and activated

lysosomes at 50 µg/ml concentrations. Lysosomal enzymes did not enhance herpes virus-induced giant cell formation.

- 0189 VIRUSES AND RENAL CARCINOMA OF *RANA PIPIENS*: IX. THE INFLUENCE OF TEMPERATURE AND HOST CELL ON REPLICATION OF FROG POLYHEDRAL CYTOPLASMIC DEOXYRIBOVIRUS (PCDV). (E.) Gravell, M. (St. Jude Child. Res. Hosp., Memphis, Tenn.) and A. Granoff. *Virology* 41(4):596-602, 1970.

Cells from fathead minnow, baby hamster kidney and chicken embryo were incubated in temperature ranges from 8-33°C to study the replication of a polyhedral cytoplasmic deoxyribovirus obtained from tumor-bearing frogs. No significant virus replication occurred in any cell type at either 8°C or 10°C, but at 12°C replication occurred in all cell types used. However, yields of polyhedral cytoplasmic deoxyribovirus and rate of production at 12°C were greater in cells from cold-blooded than from warm-blooded vertebrates. Furthermore, the viral latent period at 12°C was shorter in fathead minnow cells (12-24 hr) than in either baby hamster kidney (2-3 days) or chicken embryo cells (3-4 days). As the temperature was raised from 12 to 30 or 31°C, the viral latent period decreased, the rate of multiplication increased, and high titers of infectious virus were obtained over a broad temperature range in all cells. At 30°C to 31°C, there was little difference in the latent periods or in the rates of polyhedral cytoplasmic deoxyribovirus replication in cells originating from poikilotherms or homeotherms. Irrespective of cell type, both yield and rate of virus replication were reduced at 32°C. Infectious progeny virus was not made in any cell type at 33°C, but virus-specific macromolecules were formed at this temperature. Data from temperature shift experiments (33.5°C → 24°C) suggested that a temperature-sensitive event occurred late in the virus replication cycle, possibly at assembly of viral components. The virus yield and replication rate appear to be controlled by the host cell, although the permissive temperature for replication is controlled by the viral genes.

- 0190 STUDIES ON THE MAMMARY TUMOR AGENT (MTA): I. COMPARATIVE CYTOCHEMISTRY OF NUCLEIC ACID AND PROTEINS IN NORMAL RIIIf, C57BL MAMMARY GLANDS, AND IN MALIGNANT CELLS OF SPONTANEOUS MAMMARY TUMORS OF RIII AND VIRUS-INDUCED TUMORS IN C57BL. (E) El-Fiky, S. M. (Inst. Med. Res., Camden, N. J.). *Acta Histochem* 36(2):356-367, 1970.

Metabolic alterations in tumor cells of mice bearing both spontaneous (RIII strain) and virus-induced (C57BL and RIIIf) mammary adenocarcinoma were investigated by cytochemical estimations of RNA, DNA, and total and basic proteins in tumor cells. No significant differences in the topographical distribution of RNA, DNA, total and basic proteins were observed. However, the concentration of all of these constituents decreased from highest in tumor cells of spontaneous mammary tumors, followed by virus-induced tumor cells, and then normal mammary gland epithelium. No difference in the intensity of the cytochemical parameters studied was detected for cells of normal mammary glands of the 2 strains. The difference

in concentrations of nucleic acids and basic proteins in virus-induced C57BL tumors compared to spontaneous tumors in RIII mice could be due to alterations of the microchemical environment favoring the synthesis and release of virus and leading to the suppression of the metabolic rate of induced tumor cells.

- 0191 UNIQUE GLYCOPROTEIN FROM MOUSE MILK CONTAINING THE MAMMARY TUMOR AGENT. (E.) Miroff, G. (Dept. Biol., Union Coll., Schenectady N. Y.), H.M. Meade, M. Winetroun and H.V. Lamberson. *Nature* 227(5264):1243-1244, 1970.

A unique chemical determinant which is antigenic in rabbits was isolated and identified in mouse milk containing the mammary tumor agent. The isolation and purification process included CaCl_2 precipitation, ammonium sulfate precipitation, ECTEOLA-cellulose chromatography, Sephadex G-100 column chromatography, and preparative disc electrophoresis. The isolated antigen was not inactivated by neuraminidase, amylase, lysozyme, or chloroform-methanol extraction, but was inactivated when heated for 1 hr at 70°C or treated with pronase at 37°C for 1 hr.

- 0192 MOUSE STRAIN AND BREEDING STIMULATION AS FACTORS INFLUENCING THE EFFECT OF THYMECTOMY ON MAMMARY TUMORIGENESIS. (E.) Squartini, F. (Med. Sch. Pisa, Italy), M. Olivi and G. B. Bolis. *Cancer Res* 30(7):2069-2072, 1970.

Thymectomies were performed on newborn BALB/cf(C3H), BALB/cf(RIII), and RIII strain mice which carried spontaneous mammary tumor virus infection to determine the effect of this operation on tumorigenesis. In BALB/cf(C3H) virgin females, thymectomy decreased mammary tumor incidence from 82 to 46% and delayed tumor onset by about 5 months; in BALB/cf(RIII) force-fed females, thymectomy delayed tumor onset by about 2 months but did not significantly affect the final mammary tumor incidence. In RIII females, either virgins or breeders (normal and force-bred), thymectomy had no effect on frequency and onset of mammary tumors. Mouse strain and breeding condition does appear to influence the effect of thymectomy and the immunological responsiveness of the host animal to virus induced tumorigenesis.

- 0193 MAMMARY TUMORS IN STRAINS BL/LyDe AND SWR/LyDe MICE. (E.) Deringer, M. K. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Nat Cancer Inst* 45(2):215-218, 1970.

The presence of mammary tumor virus was demonstrated in strain BL/LyDe mice by the induction of mammary tumors in agent-free substrains C3Hf/HeDe and C3HeB/De mice foster-nursed by BL/LyDe mice. The incidence of mammary tumors in breeding females of strain BL/LyDe was 10% at an average age of death of 15.5 months, while the incidence of mammary tumors in foster-nursed females of strains C3Hf/HeDe and C3HeB/De at an average age of 18 months was 47% (controls, 2% and 4%). The types of mammary tumors produced were adenocarcinomas Type A and Type B. The incidence of mammary tumors in C3Hf/HeDe and C3HeB/De

foster-nursed by SWR/LyDe females was 4% at an average age of death of 25 months, indicating that strain SWR/LyDe mice either do not possess mammary tumor virus or do not transmit it to foster-nursed animals.

- 0194 MOUSE MAMMARY TUMOR VIRUS INFECTIVITY AS A FUNCTION OF AGE AT INOCULATION, BREEDING, AND TOTAL LAPSED TIME. (E.) Moore, D. H. (Inst. Med. Res., Camden, N. J.), J. Charney and B. D. Pullinger. *J Nat Cancer Inst* 45(3):561-565, 1970.

Mouse mammary tumor virus-containing milk (tumor incidence, 84%) was injected i.p. into tumor- and virus-free mice at from 2-12 wk after birth at doses of 0.2 ml/mouse to investigate the effect of inoculation age on viral infection and its correlation with the eventual development of mammary tumors; antigen was assayed with rabbit anti-mammary tumor virus antiserum on micro-Ouchterlony plates. Over the age range of 2-10 wk, the total lapsed time from inoculation to the appearance of antigen in the milk or the development of tumors was approximately constant, irrespective of age at inoculation; however, inoculation at 12 wk of age gave a relatively lower incidence of infection and tumor development. All age groups had a gradual increase in antigen incidence from the first to the third lactation. Force-breeding to the second or third lactation of mice inoculated at age 10 and 12 wk did not shorten the lapsed time for obtaining equivalent antigen incidences. Inoculation during first pregnancy gave negative antigen-assay results at the third and even at the sixth lactation. Inoculating mice at ages between 4 and 10 wk, mating them at 10-12 wk, and testing their milk at the second lactation gave a practical assay requiring about 15 wk.

- 0195 ISOLATION OF MURINE SARCOMA VIRUS-TRANSFORMED MOUSE CELLS WHICH ARE NEGATIVE FOR LEUKEMIA VIRUS FROM AGAR SUSPENSION CULTURES. (E.) Bassin, R. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), N. Tuttle and P. J. Fischinger. *Int J Cancer* 6(1):95-107, 1970.

A subline of mouse 3T3 cells was infected with the Moloney isolate of murine sarcoma virus, and colonies of transformed cells were produced in semi-solid agar suspension cultures. At optimal cell concentrations, the number of colonies formed was proportional to the concentration of murine sarcoma virus, although the same virus preparation gave 2-hit titration patterns in focus assays using monolayer cultures of 3T3 cells. Individual colonies were picked from agar suspension cultures and grown as monolayers. Some of the colonies selected gave rise to cell lines which yielded detectable quantities of focus-forming murine sarcoma virus, while others did not. Five lines which did not yield detectable murine sarcoma virus were superinfected with murine leukemia virus; focus-forming murine sarcoma virus was subsequently detected in 3 of the 5 lines. These 3 lines, therefore, probably contain the murine sarcoma virus genome in the absence of infectious leukemia virus and are termed "sarcoma-positive leukemia-negative" mouse cells.

One sarcoma-positive leukemia-negative cell line, in addition to releasing murine sarcoma virus after superinfection with murine leukemia virus, responded with the formation of murine sarcoma virus-type foci in proportion to the concentration of murine leukemia virus used for superinfection. This line is composed of two morphological cell types, one indistinguishable from murine sarcoma virus-transformed 3T3 cells and the other normal in appearance. Focus formation in this cell line has been used to develop an assay system for Friend, Moloney and Rauscher leukemia viruses. Colony formation in semi-solid agar appears to be an effective means of separating murine sarcoma virus infection and cell transformation from murine leukemia virus infection and replication.

- 0196 USE OF A MURINE SARCOMA VIRUS IN AN *IN VIVO* ASSAY FOR ANTIVIRAL AND ANTITUMOR AGENTS. (E.) Pearson, J. W. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), W. T. Gibson and M. A. Chirigos. *Cancer Res* 30(7):2024-2028, 1970.

A plasma variant of the Moloney sarcoma virus with infection characteristics suitable for evaluation of potential antiviral agents is described. Inoculation i.p. of this virus into adult mice resulted in a progressive splenomegaly. The enlarged spleens were firm and contained multiple cream-white areas, and inguinal and cervical lymph nodes were enlarged markedly. The degree of splenomegaly was dependent on the initiating dose of virus, which permits the use of spleen weight as a parameter for quantitative measurement of virus titer. Extracellular virus was recoverable from the plasma 3 days after infection, before there was any significant increase in spleen weight; in addition, virus was recoverable from infected spleen and liver 5 days after inoculation. Two drugs, melphalan and 1,3-bis(2-chlorethyl)-1-nitrosourea tested for antiviral activity against the murine sarcoma virus (plasma variant Moloney strain), were effective in retarding splenomegaly, decreasing virus titer, and increasing median survival time.

- 0197 ACCELERATION BY THYMOSIN OF THE DEVELOPMENT OF RESISTANCE TO MURINE SARCOMA VIRUS-INDUCED TUMOR IN MICE. (E.) Zisblatt, M. (Albert Einstein Coll. Med., Yeshiva U., Bronx, N. Y.), A. L. Goldstein, F. Lilly and A. White. *Proc Nat Acad Sci* 66(4):1170-1174, 1970.

Moloney murine sarcoma virus was inoculated into mice of various ages that were injected with a liver or spleen extract or with thymosin from day 2-14 after birth to study the effect of the thymic extract on the development of resistance to progressive tumor growth. Resistance in CBA/Wh mice, at the virus dose used, was first detected at approximately 2 wk of age and was completely developed at 5 wk. Thymosin administration to newborn mice significantly accelerated the rate of development of resistance to progressive tumor growth; thymosin-treated mice challenged with virus at 2 wk had the same survival rate as control animals of 3 wk. Liver- and spleen-treated mice did not differ from control. The data suggest a humoral role for the thymus in the development of tumor immunity and that the use of thymus-

derived extracts can accelerate the development of cell-mediated immunological competence.

- 0198 RADIOLOGICAL STUDIES ON THE CHRONOLOGICAL RELATION BETWEEN MURINE SARCOMA VIRUS INFECTION AND CELL CYCLE. (E.) Yoshikura, H. (Fac. Sci. Orsay, France). *J Gen Virol* 8(2):113-120, 1970.

Cell cultures originating from kidney tissues of newborn mice were infected with murine sarcoma virus and subjected to UV irradiation (10 ergs/mm²/sec) to investigate the intracellular replication of the virus as affected by UV. In experiments with unsynchronized cultures UV sensitivity of the cells infected with murine sarcoma virus as focus centers increased with the lapse of time after infection, and 16 hr after infection UV-resistant cells appeared which were probably producing mature virus. The UV-resistant population continued to increase thereafter. Ultraviolet sensitivities as focus centers of synchronized cells infected with murine sarcoma virus at different periods of the cell cycle were compared 23 hr after infection. The cells infected with the virus in the G1 phase remained more sensitive to UV light than those infected with the virus in the S phase, resulting in a longer latent period after G1 phase infection than after S phase infection. An antimitotic agent, colchicine, prevented the increase of UV resistance of the cells as focus centers. The findings indicate that virus replication is synchronized at the stage of host cell division in the cell cycle, and that murine sarcoma virus infection requires division of host cells.

- 0199 MURINE SARCOMA VIRUS TRANSFORMATION OF BALB/3T3 CELLS: LACK OF DEPENDENCE ON MURINE LEUKEMIA VIRUS. (E.) Aaronson, S. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), J. L. Jainchill and G. J. Todaro. *Proc Nat Acad Sci* 66(4):1236-1243, 1970.

The pattern of focus formation induced by murine sarcoma virus in mouse cells was studied in BALB/3T3 cells. Early after infection with murine sarcoma virus (and murine leukemia virus which is present in murine sarcoma virus stocks), the pattern of focus formation was "two-hit" or one which required the presence of both viruses in the initially infected cell. However, after 7 days, the focus formation pattern became "one-hit" or one which was entirely dependent upon cell division of the originally infected cell and which was due to infection by murine sarcoma virus alone. The "two-hit" pattern resulted from the inability to detect the "one-hit" foci early after infection. These data indicate that murine sarcoma virus is able to transform mouse cells without requiring murine leukemia virus.

- 0200 TUMORS INDUCED IN THE SOUTH AMERICAN MARMOSET MONKEY BY ROUS SARCOMA VIRUS. (E.) Noyes, W. F. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.). *J Nat Cancer Inst* 45(3):579-587, 1970.

The Carr-Zilber and Schmidt-Ruppin strains of the Rous sarcoma virus were used to induce metastasizing

epoasms in newborn and adult South American marmosets. Two of 8 adult cottontop marmosets [*Saguinus oedipomidas*] inoculated with the Carr-ilber strain developed slowly growing fibrosarcomas and spindle cell sarcomas; while 11 of 12 adult cottontop marmosets and white-lipped tamarin marmosets (*S. nigricollis* group) inoculated with the Schmidt-Ruppin strain developed rapidly growing round cell and spindle cell sarcomas, frequently with multinucleated giant cells. These tumors frequently became very large (25-45 cm²) and metastasized regularly to lymph nodes but infrequently to the lungs. Death from Schmidt-Ruppin-induced tumor in adults usually occurred in 6-8 weeks. In newborn animals inoculated with this strain, the latent period was as short as 25 days before the development of invasive and metastatic spindle and round cell sarcomas, and terminal stages were reached in 3-6 weeks. Two adult marmosets developed sarcomas after inoculation with a cell-free filtrate of the Schmidt-Ruppin strain. No spontaneous neoplasms were observed in the marmoset colony over a 6-year period.

0201 A FULL EXPRESSION OF THE GENOME OF ROUS SARCOMA VIRUS IN HETEROKARYONS FORMED AFTER FUSION OF VIROGENIC MAMMALIAN CELLS AND CHICKEN FIBROBLASTS. (E.) Machala, O. (Czechoslovak Acad. Sci., Prague), L. Donner and J. Svoboda. *J Gen Virol* 8(3): 19-229, 1970.

Inactivated Sendai virus was used to obtain cell fusion of virogenic hamster cells and indicator chicken cells; immunofluorescence and autoradiographic tests were performed which indicated that all heterokaryotic cells formed after fusion produced Rous sarcoma virus coat antigen. Homokaryons and mononuclear cells of both types were negative in the immunofluorescence test. Similarly, all tested single heterokaryons obtained by visually controlled cell fusion produced infectious Rous sarcoma virus. Virus coat antigen or infectious virus was not formed in virogenic cells or chicken fibroblasts agglutinated but not fused in the mixture with Sendai virus, or in heterokaryons obtained after fusion of virogenic cells with chicken erythrocytes, including heterokaryons containing 'reactivated' chicken erythrocyte nuclei. An important role in the process for Rous sarcoma virus appears to be played by heterokaryons formed after fusion of virogenic cells with chicken fibroblasts, which seem to be permissive cells for that virus.

0202 GLYCOPROTEIN COMPONENTS OF AVIAN AND MURINE RNA TUMOR VIRUSES. (E.) Duesberg, P. H. Virus Lab., U. California, Berkeley), G. S. Martin and P. K. Vogt. *Virology* 41(4):631-646, 1970.

Component isolation procedures carried out on different strains of Rous sarcoma virus and Rauscher mouse leukemia virus resulted in the isolation of glycoproteins containing glucosamine, galactose and fucose. Polyacrylamide gel electrophoresis in sodium dodecyl sulfate indicated that the molecular weight of the major glycoprotein of Rous sarcoma virus was between 90,000-105,000 daltons, depending on the strain of the virus; the minor glycoprotein had an

approximate molecular wt of 37,000. Both glycoproteins had higher molecular wts than the proteins of the group specific antigen of avian tumor viruses. The glycoproteins represented between 10% and 20% of the radioactive protein of purified virus. Disruption of Rous sarcoma virus with sodium dodecyl sulfate yielded glycoprotein components with sedimentation coefficients between 4 S and 2 S. The glycoprotein derived from Tween 20-disrupted virus was obtained in a 4-2 S form and in an 8 S form. The 8 S component consisted predominantly of a multimeric aggregate of the two viral glycoprotein components, and some group-specific antigen. Glycoproteins of different strains of avian tumor virus are probably part of or identical with the viral type- or subgroup-specific antigen, since both the 8 S and the 4-2 S glycoprotein derived from Tween 20-disrupted Rous sarcoma virus specifically inhibited virus neutralizing antibody, and since the glycoproteins of different strains of Rous sarcoma virus had different electrophoretic mobilities.

0203 PRESENCE OF DNA IN ROUS SARCOMA VIRUS. (E.) Levinson, W. (Dept. Microbiol. U. California, San Francisco), J. M. Bishop, N. Quintrell and J. Jackson. *Nature* 227(5262):1023-1025, 1970.

DNA was isolated from purified Rous sarcoma virus (Schmidt-Ruppin strain). The virus was doubly labeled with ³H-thymidine and ¹⁴C-uridine and analyzed by isopycnic centrifugation. The labeled nucleic acid extracted from the virus was sensitive to deoxyribonuclease, but not to ribonuclease or 1 M NaOH. When sonicated ³H-thymidine-labeled uninfected chick embryo cells and unlabeled Rous sarcoma virus were mixed and purified by centrifugation, no ³H-thymidine counts were associated with the purified virus, establishing that the DNA isolated from the virus was an intraviral entity and not cellular DNA. The bulk of the DNA sedimented slightly ahead of the 4S RNA of the virus and a small part cosedimented with the 65S RNA; electrophoretic migration patterns indicated that the 65S DNA was not covalently linked to 65S RNA.

0204 ANALYSIS OF A FUNCTIONAL CHANGE IN MEMBRANE IN THE PROCESS OF CELL TRANSFORMATION BY ROUS SARCOMA VIRUS: ALTERATION IN THE CHARACTERISTICS OF SUGAR TRANSPORT. (E.) Hatanaka, M. (Publ. Hlth. Res. Inst. New York, New York) and H. Hanafusa. *Virology* 41(4):647-652, 1970.

Alterations in the kinetics of the uptakes of glucose and some other sugars coincident with the morphological changes occurring during the process of Rous sarcoma virus infection were studied in chick embryo cells. An increase in the uptake of D-glucose, 2-deoxy-D-glucose and D-glucosamine (assayed by isotope uptake) was first observed at 16 hr after inoculation of the culture; at this time morphological changes also became recognizable in 15% of the cell population. The ratio of uptake into infected to that into noninfected cultures at 42 hr postinfection were 13.3, 8.4 and 21.9 for D-glucose, 2-deoxy-D-glucose and D-glucosamine, resp. In infected cultures with glucose in the medium, the decrease in glucose was accompanied by a concomitant

increase in lactic acid. The uptake of 2-deoxy-D-glucose seemed to follow most closely the degree of cell transformation in infected cultures. A non-transforming C type particle (RAV-2) infection of chick embryo cells showed no alterations in sugar transport.

- 0205 ROUS SARCOMA VIRUS: A FUNCTION REQUIRED FOR THE MAINTENANCE OF THE TRANSFORMED STATE. (E.) Martin, G. S. (Virus Lab., U. California, Berkeley). *Nature* 227(5262):1021-1023, 1970.

The isolation of a temperature-sensitive mutant of the Schmidt-Ruppin strain of Rous sarcoma virus, the properties of which indicate that mutation affects a function required for the maintenance of the transformed state but not for growth of the virus, is described. Survivors of a crude stock of SR-RSV-A virus which had undergone mutagenic treatment with N-methyl-N'-nitro-N-nitrosoguanidine (2 mg/ml) were cloned at 35-36°C using an agar suspension of chick fibroblasts. One of the 6 mutants isolated which were able to form foci at 36°C but not at 41°C was selected for study. The rate of virus accumulation and the rate of inactivation was the same for both the mutant and the wild type at 41°C, indicating that mutation did not affect the growth of the virus. When T1-transformed cells (at 36°C) were shifted to 41°C, the cells rapidly lost their rounded refractile appearance and assumed a near-normal appearance within 4 hr; cells infected by the wild type virus were unaffected by the temperature shift. The reverse change, when T1-infected cells grown at 41°C were shifted to 36°C and became completely transformed, was slower, taking about 2 days. Part of the viral genome required for maintenance of the transformed state is apparently lost or inactivated at the non-permissive temperature in this mutant, although its growth is not affected.

- 0206 CHARACTERISTICS OF CORES OF AVIAN LEUKO-SARCOMA VIRUSES. (E.) Bader, J. P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), N. R. Brown and A. V. Bader. *Virology* 41(4):718-728, 1970.

Mixtures of the tumorigenic Rous sarcoma virus and Rous associated virus were treated with Tween 80 in ethyl ether, phospholipase A or C, and density gradient centrifugation. Cores labeled with ³H-uridine had a density (1.27 g/ml) different from intact virus (1.16 g/ml) and could be separated by isopycnic banding in potassium tartrate, cesium sulfate, or sucrose gradients. The viral RNA within the cores was susceptible to ribonuclease, and the general instability of cores may be partly explained on this basis. Cores obtained from murine leukemia virus had properties similar to those of Rous sarcoma virus and Rous associated virus. Density-purified cores exhibited complement-fixing activity when mixed with group-specific antiserum, but most of the group specific antigen was solubilized during processing of virions. The findings suggest that the virion core probably plays a role only in the absorption and penetration of cells, and that intact cores are infectious only if access to the cell is provided.

- 0207 SENDAI VIRUS RNA AS MESSENGER RNA DETERMINING THE SYNTHESIS OF EARLY VIRUS SPECIFIC PROTEINS. (E.) Mekler, L. B. (Acad. Med. Sci., Moscow, USSR), M. A. Shlyankevich and V. J. Shevliaghyn. *Arch Ges Virusforsch* 30(4):309-315, 1970.

The effect of Sendai virus inactivated by ultraviolet irradiation (BUV-30 germicidal tube at 6 cm for 12 min) or β -propiolactone (final concentration of 0.1%) on cell properties was studied in an HRT-CEF cell mixture (hamster Rous tumor and chick embryo fibroblast cells). The inactivated virus induced synthesis of early virus-specific proteins (virus-induced cell antigen) without virus-specific RNA, suggesting that mRNA for the synthesis of early proteins of Sendai virus is the virion RNA (plus strand). Only one strand of viral nucleic acid is transcribed in the cell and if the structural proteins are coded in the minus strand, the absence of structural protein synthesis with the inactivated virus is obvious.

- 0208 CELO VIRUS: AN ONCOGENIC VIRUS: BRIEF REPORT. (E.) Mancini, L. O. (Union Carbide Res. Inst., Tarrytown Tech. Ctr., N. Y.), V. J. Yates, J. Anderson and V. Jasty. *Arch Ges Virusforsch* 30(2-3):257-260, 1970.

The chicken-embryo-lethal-orphan (CELO) virus was established as an oncogenic virus in golden Syrian hamsters in this study. Infectious virus particles were isolated from the cell suspensions of 2 tumors, from the pelleted extracts of 3 neoplasms, and from tumor cell cultures; various control systems failed to yield infectious virus particles. Plaque purified CELO virus was mixed with an equal amount of undiluted serum from tumor-bearing or normal hamsters and was allowed to incubate at room temperature for 1 hr; embryonated eggs were inoculated with the various samples via the allantoic sac. Protection, as indicated by viable healthy embryos after 10 days, was proof of the presence of type-specific CELO antibody in the tumored hamsters; sera from control animals failed to neutralize the test dose. When hamsters immunized with CELO virus were challenged with tumor cells the transplants were completely rejected; polyoma and Schmidt-Ruppin Rous sarcoma tumor cells produced tumors in both the CELO-immunized and non-immunized hamsters at the same rate. These data, along with the finding of type specific CELO "T" antigen in tumor cells by the fluorescent antibody technique, confirm the oncogenicity of CELO virus.

- 0209 VIRUS-SPECIFIED DEOXYRIBONUCLEIC ACID IN SIMIAN VIRUS 40-EXPOSED HAMSTER CELLS: CORRELATION WITH S AND T ANTIGENS. (E.) Levine, A. S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), M. N. Oxman, P.H. Henry, M. J. Levin, G. T. Diamandopoulos and J. F. Enders. *J Virol* 6(2):199-207, 1970.

Hamster embryonic cell lines infected by SV40 were examined for the presence of cellular DNA complementary to tritiated viral RNA synthesized *in vitro* by hybridization techniques. The methods employed permitted the detection of 10^{-5} μ g of viral DNA in 100 μ g of cellular

NA, corresponding to one-fifth of an SV40 DNA molecule per cell. Those lines which contained both the SV40 surface (S) and tumor (T) antigens also contained DNA complementary to SV40 RNA synthesized *in vitro*. In contrast, neither of two lines which contained surface, but not tumor antigen contained detectable DNA complementary to SV40 RNA. Although current methodology cannot exclude the presence of a single copy of one viral gene per cell, these results suggest that the continued synthesis of S antigen does not require the persistence of SV40 DNA in the transformed cells.

0210 THYMIDINE KINASE ACTIVITY AND DNA SYNTHESIS IN CELLS INFECTED WITH THE PARVOVIRUS H-1. (E.) Fong, C. K. Y. (Putnam Mem. Hosp. Inst. Med. Res., Bennington, Vermont), N. Ledinko and H. W. Toolan. *Proc Soc Exp Biol Med* 134(4):1199-1203, 1970.

Simian virus 40 transformed newborn human kidney cell cultures were infected with H-1 stock virus, resulting in a marked drop in the rate of incorporation of ³H-thymidine into DNA late in infection. Autoradiographic measurements revealed that the inhibition of total DNA synthesis was due to a decrease in the capacity of an infected cell to synthesize DNA. Thymidine kinase activity increased 1.5- to 2.6-fold during a period of virus maturation (20-48 hr), but, later in infection, it decreased to 11-43% of the control cell activity. A similar decline in enzyme activity was also observed in "Salk monkey heart" cells late after H-1 infection. Extracts prepared from newborn human kidney cells infected for different times had no effect on the enzyme activity from uninfected cells. The decrease in thymidine kinase activity found after H-1 infection relative to control cell activity was apparently dependent on *de novo* protein and DNA-dependent RNA synthesis.

0211 RADIATION-ENHANCED ONCOGENESIS BY SV40. (E.) Coggin, J. H. (Oak Ridge Natl. Lab., Tenn.), S. E. Harwood and N. G. Anderson. *Proc Soc Exp Biol Med* 134(4):1109-1111, 1970.

Hamster and mouse embryo cells exposed to X-irradiation prior to infection with simian virus 40 showed an increased frequency of transformation *in vitro*. Neonatal hamsters were tested for increased sensitivity to simian virus 40 tumorigenicity after exposure to localized, low-level X-ray at the site of virus inoculation *in vivo*. Irradiation of a target area prior to infection markedly decreased the time to tumor appearance and increased the frequency of tumor occurrence. No tumors occurred in irradiated animals that did not receive virus. Although low doses of localized X-ray may have resulted in modest immunologic suppression, this was not a primary factor in tumor enhancement. Tumors appearing in simian virus 40 infected animals uniformly possessed viral neoantigens.

0212 STUDIES ON THE BIOCHEMICAL PROPERTIES OF SURFACE COMPONENT OF NORMAL AND SV-40 TRANSFORMED 3T3 MOUSE CELLS. (E.) Sheinin, R.

(Ontario Cancer Inst., Toronto, Canada) and K. Onodera. *Canad J Biochem* 48(8):851-857, 1970.

Biochemical and biophysical properties of isolated and partially purified (sonication, dialysis, and DEAE-cellulose column chromatography) surface components of 3T3 and SV40-transformed 3T3 mouse cells were examined. The incorporation patterns of various radioactive precursor substances (glucosamine, amino acids, choline, uridine, and thymidine) into the surface component indicated that the components contain carbohydrate and peptide (probably as glycoprotein) but do not contain lipid, RNA, or DNA. Both velocity sedimentation in sucrose density gradients and gel filtration (Sephadex G-200) indicated that the surface molecule is large, and may have a molecular weight of 60,000 Daltons.

0213 REACTION OF SERUM FROM PREGNANT HAMSTERS WITH SURFACE OF CELLS TRANSFORMED BY SV40. (E.) Duff, R. (Coll. Med. U. Pennsylvania, Hershey) and F. Rapp. *J Immun* 105(2):521-523, 1970.

The surface antigen on SV40-transformed Syrian hamster cells was compared to an antigen found during hamster embryonic development. When sera from pregnant hamsters (collected 14-15 days after onset of their second pregnancy) were incubated with cells transformed by SV40 or defective SV40, the majority (>80%) of the pregnant hamster sera reacted specifically with the cell surfaces; no reaction was observed with normal cells. In another experiment, pregnant sera did not react with hamster cells transformed by simian adenovirus 7 or by dimethylbenzanthracene, indicating a definite specificity of the pregnant sera for SV40 transformed cells. The antibody was present in sera of 1 out of 7 hamsters pregnant for the first time, but in 5 of 6 animals pregnant for the second time; 1 week after termination of pregnancy, the antibody was no longer detectable in the hamsters.

0214 THE SUPERINFECTION OF ABORTIVELY INFECTED MONKEY KIDNEY CELLS WITH SV40: BRIEF REPORT. (E.) Sauer, G. (German Cancer Res. Ctr., Heidelberg) and E. C. Hahn. *Arch Ges Virusforsch* 30(2-3):267-270, 1970.

The relation of abortive infection with SV40 and resistance to super-infection was studied in African green monkey kidney cells (GMK) by observing the presence of viral coat protein and tumor-antigen with immunofluorescence. Infection with SV40 (3 plaque forming units (PFU)/cell) produced 17% abortively infected cells and 70% cells with both viral coat protein and tumor-antigen. Superinfection (20 PFU/cell) of cells 24 and 48 hr after the first infection with 3 PFU/cell resulted in 100% of the cells having viral coat protein. The lack of resistance indicates that the incomplete viral information in the abortively infected cell does not affect the susceptibility of these cells to productive superinfection.

0215 POLYOMA VIRUS TRANSFORMATION OF 3 HAMSTER CELL LINES *IN VIVO*: ELECTROPHORETICAL STUDIES. (It.) Fimiani, V. (Fac. Med. U. Perugia,

Italy) and F. Bistoni. *Boll Ist Sieroter Milan* 49(2):164-168, 1970.

Electrophoretic migration of 3 transformed cell lines (B-, G- and F-) originating from an LID-I strain polyoma virus-induced s.c. hamster tumor was compared to migration of normal cells (kidney fibroblasts and red blood cells) obtained from a healthy hamster. A Gittens-James instrument (cells containing a 3.5 M soln of KCl) was used; the applied current was 50 V and 5 mA, and the experiments were performed at room temperature (17-19°C). The 3 transformed cell lines revealed a higher migration rate (higher surface negative charge) than the control cells. The F-cell line presented the highest migration rate of the transformed cell lines; this was attributed to their having the largest number of sialic acid residues on the cell surface. However, no direct relation between membrane sialic acid levels and cell malignancy was established.

0216 REQUIREMENT OF SERUM FOR DNA SYNTHESIS IN BHK 21 CELLS: EFFECTS OF DENSITY, SUSPENSION AND VIRUS TRANSFORMATION. (E.) Clarke, G. D. (Imperial Cancer Res. Fund., London, England), M. G. P. Stoker, A. Ludlow and M. Thornton. *Nature* 227(5260): 798-801, 1970.

The serum requirement of both normal and transformed cells in culture in different conditions of density and anchorage were determined. The BHK 21 hamster cell line (Cl3 clone) and a polyoma virus transformed derivative were grown in Dulbecco's modified Eagle's medium containing 10% calf serum and ³H-thymidine. Layers of resting cells originally seeded at different densities were exposed to increasing serum concentrations; the BHK 21 cells showed density dependent inhibition of DNA synthesis in low concentrations of serum. In virus-transformed cells, the initial response to serum was very high because a large proportion of cells were synthesizing DNA even in 0.2% serum; in over half of the transformed cells, DNA synthesis occurred in the complete absence of serum. With the transformed cells, there was little difference between anchored and suspended cells, whereas in the normal BHK 21 cells, suspended cells were 60 times less sensitive to serum concentration than anchored cells; the latter showed a 3-fold decrease in sensitivity when the density increased 10-fold. The requirement for a serum factor for initiation of DNA synthesis which is necessary for normal cells appears to be removed or greatly reduced in the virus-transformed cells.

0217 ENZYMATIC METHYLATION OF TRANSFER RNA BY EXTRACTS OF POLYOMA VIRUS-TRANSFORMED CELLS. (E.) Breier, B. (Mount Sinai Sch. Med., New York, N. Y.) and R. W. Holley. *Biochim Biophys Acta* 213(2): 365-370, 1970.

Enzymatic methylation of *Escherichia coli* tRNA and rat liver tRNA *in vitro* by extracts of polyoma virus-transformed cells (HPy, 3T3, 3T3Py, BHKPy, and BHK) was studied using ¹⁴C-S-adenosyl-L-methionine (labeled in the methyl group). With *E. coli* tRNA as substrate in the polyoma virus-transformed HPy cell line,

(from hamster) fluctuations occurred in the activities of 5 different tRNA methylases (specific for N²-methylguanine, N¹-methylguanine, N²,N²-dimethylguanine, N¹-methyladenine, and 5-methyluracil) at pH values of 7.2, 8.0, and 8.8, while with rat liver tRNA as substrate only the N¹-methylguanine-specific methylase had any activity (53 cpm) at pH 8.8. The mouse cell line 3T3 and its transformed cell line 3T3Py yielded similar results with the N¹-methylguanine-specific methylase activities (cpm) at 30 and 25, resp., with *E. coli* tRNA at pH 8.8 and at 22 and 62, resp., with rat liver tRNA at the same pH. The BHK cell line of hamster cells and its transformed BHKPy yielded N¹-methylguanine-specific methylase activities of 96 and 115, resp., with *E. coli* tRNA and of 42 and 96, resp., with rat liver tRNA. The hypothesis for a polyoma virus-induced tRNA methylase is not supported.

0218 RNA SYNTHESIS IN POLYOMA VIRUS-INFECTED CELLS: I. PATTERN OF FORMATION OF POLY-RIBOSOME-ASSOCIATED MESSENGER RNA DURING PRODUCTIVE INFECTION. (E.) Cheevers, W. P. (Cancer Res. Lab., U. Western Ontario, London, Canada) and R. Sheinin. *Canad J Biochem* 48(10):1104-1112, 1970.

Secondary cultures of mouse embryo cells were infected with polyoma TSPI virus at an estimated input multiplicity of 1-10 PFU/cell to investigate the pattern of formation of polyribosome-associated mRNA in polyoma-infected mouse embryo cells. It was found that productive infection of these cells by polyoma virus resulted in stimulation of mRNA synthesis; the pattern of induction of mRNA synthesis was biphasic, characterized by distinct early and late periods, as denoted by the time of initiation of progeny viral DNA replication. The formation of early mRNA was first detected at 9-11 hr post-infection, 6 hr prior to the time of onset of virus-induced synthesis of cell DNA and 9 hr prior to initiation of polyoma DNA replication. The initiation of synthesis of late mRNA was approximately coincident with the onset of formation of viral DNA. Most of the newly synthesized "early" and "late" mRNA was of relatively small size (8-12 S) and was associated with polyribosomes which sedimented at less than 180 S. The mRNA which was synthesized both early and late was predominantly cell-specific but the ratio of total late mRNA which was virus-specific was 3 times higher than the ratio of total early mRNA.

0219 PRELIMINARY VIROLOGICAL AND IMMUNOLOGICAL STUDIES OF THE SALIVARY GLAND TUMOR OF C₃H/He MOUSE. (E.) Castelli, L. (Regina Elena Inst. Cancer Res., Rome, Italy) and A. Caputo. *Experimentia* 26(7):780-781, 1970.

An attempt to isolate an agent identical with or similar to polyoma virus from the salivary gland tumor of C₃H mice is described. Polyoma virus particles were not found in tumor cell cultures; and no cytopathic effect was apparent after the addition of cellular suspensions or cell-free tumor extracts of polyoma virus to mouse embryo cell cultures. In addition, when polyoma virus was artificially introduced into the system a slight de-

crease of tumor takes was obtained, confirming that the etiology of this tumor cannot be restricted to polyoma virus. Immunological studies in mice inoculated with homogenized tumor cells followed by challenge with whole tumor cells indicated that the tumor was unable to produce an appreciable immunological response in isogenic hosts.

0220 ISOLATION, ANALYSIS AND RADIOACTIVE LABELING OF NUCLEIC ACIDS OF POLYOMA VIRUS-INDUCED TUMORS IN RATS. (Ger.) Pokorny, J. (Borstel Res. Inst. Germany), E. Fasske, R. Fetting and S. Reth. *Z Krebsforsch* 74(3):219-226, 1970.

Inoculation of a polyoma virus (strain BB/T2, cultured for 6 yr on mouse embryonic cell cultures) into newborn Wistar rats induced the development of 5 histologically different transplantable tumors. The fibrosarcomas and liposarcomas contained AT-type DNA while the other tumor types, adenocarcinomas, solid carcinomas and rhabdomyosarcomas contained the GC-type of DNA; control normal tissues contained mainly GC-type DNA. The number of purine and pyrimidine bases within the tumor transplant strains was constant. Carcinomas originated in the thyroid while rhabdomyosarcomas developed in the skeletal muscle system. Distribution studies with labeled tumor DNA in organs of normal animals revealed the spleen as the main site of DNA accumulation; it is suggested that oncogenic viral DNA may similarly accumulate in the spleen.

0221 DENSONUCLEOSIS VIRUS DNA SYNTHESIS: HIGH RESOLUTION AUTORADIOGRAPHY. (Fr.) Krustak, E. (Fac. Med. U. Montreal, Quebec, Canada). *Rev Canad Biol* 29(2):207-211, 1970.

- 0222 TRANSFER OF TUMOR IMMUNITY WITH RIBONUCLEIC ACID. (E.) Pilch, Y. H. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and K. P. Ramming. *Cancer* 26(3):630-637, 1970.

Normal C3H mouse spleen cells were incubated with RNA extracted from the lymphoid organs of guinea pigs immunized with a benz(a)pyrene-induced fibrosarcoma to achieve the transfer of antitumor immunoreactivity to normal, nonimmune lymphoid cells. Injections of the immunized cells into normal C3H mice significantly inhibited the development of subsequent isografts of the same tumor. RNA from pigs immunized with normal C3H tissues was ineffective, and RNAase treatment of the RNA preparations removed all activity. Within a completely syngeneic tumor-host system, strain 2 guinea pig spleen cells were incubated with RNA extracted from the spleens of strain 2 guinea pigs previously immunized with a strain 2 guinea pig liposarcoma induced by methylcholanthrene. Immunoreactivity of these cells was demonstrated by their ability to cause areas of specific immune cytolysis in monolayers of methylcholanthrene-induced tumor cells *in vitro*. This reaction was found not to be dependent on the presence of phytohemagglutinin. RNA extracted from the spleens of guinea pigs stimulated nonspecifically by immunization with Freund's adjuvant, but not exposed to the tumor, was ineffective. Normal lymphoid cells, incubated with solubilized extracts of methylcholanthrene-induced tumor tissue known to be rich in tumor-specific transplantation antigens, but containing no RNA, failed to match the RNA preparations in production of immune cytolysis.

- 0223 RADIATION DOSE-INDEPENDENT INACTIVATION OF ISOLOGOUS MOUSE LYMPHOMA CELLS BY NONSPECIFIC RESISTANCE. (E.) Maruyama, Y. (U. Minnesota Hlth. Sci. Ctr., Minneapolis), C. Ceman and R. B. McHugh. *Cancer Res* 30(8):2245-2251, 1970.

The antigenicity of X-irradiated LSA lymphoma of C57BL mice was assessed to determine whether the tumor can be recognized and inactivated by immunologically competent recipient mice. Pretreatment of the recipient mice with X-ray-killed cells at weekly intervals for 3 weeks did not alter the TD₅₀ (cell dose required to produce 50% tumor takes among challenged recipients) so that a conventional tumor antigenicity was not detected. Tumor cells assayed in immunologically suppressed (whole body irradiation of 400 rads) and nonsuppressed recipients revealed significantly different effective fractions (0.39 and 0.13, resp.) indicating that the tumor cells were inactivated by the immune-competent host. A 2-fold increase in cell dose for the nonirradiated mice to compensate for the lower proportion of takes in the nonsuppressed group made it possible to produce comparable proportions of takes in both groups; when X-irradiated cells were assayed using this factor, similar numbers of takes were observed. A weak form of host resistance against tumor cells which reduced tumor cell survival appears to exist; this nonspecific resistance is dose independent, and is effective against small numbers of challenging cells and against single viable cells in a large population of identical nonviable cells.

- 0224 CHRONIC ALLOGENEIC DISEASE: II. DEVELOPMENT OF LYMPHOMAS. (E.) Armstrong, M. Y. K. (Dept. Microbiology, Yale U., New Haven, Conn.), E. Gleichmann, H. Gleichmann, L. Beldotti, J. Andre-Schwartz and R. S. Schwartz. *J Exp Med* 132(3):417-439, 1970.

Inoculation of parental cells (BALB/c spleen) into 371 (BALB/c A/J)F₁ hybrids triggered a sustained immunoproliferative reaction, and at the end of 24 months, a 33% incidence of reticulum cell sarcomas developed, compared to 3% for controls. The development of the neoplasms was a function of the number of parental cells administered. Analyses of the injected mice for the presence of donor cells indicated that the majority of the injected parental cells lost antihost activity, probably within 24 hr of their administration. Transplantation tests and antigenic analysis of tumor cells showed that the tumors were of host origin.

- 0225 ALLOGRAFT SURVIVAL IN NONSUSCEPTIBLE C57BL/6J MICE HOSTS: TEMPORAL RELATIONSHIP BETWEEN WHOLE-BODY X-IRRADIATION AND THE IMMUNE RESPONSE. (E.) Halkett, J. A. E. (Boston VA Hosp., Mass.). *Radiology* 96(3):645-648, 1970.

Female mice, shown to be resistant to transplants of mouse leukemia, were exposed to X-irradiation (400 rads) before or after receiving leukemia cell injections to test allograft survival in irradiated nonsusceptible hosts. Preirradiated mice died of leukemia, but postirradiated mice did not, as confirmed by transfer of homogenized spleens from irradiated allogenic hosts to AKR strain mice syngeneic with the leukemic cells. More leukemic cells developed in preirradiated hosts spleens, a finding which suggests that preirradiation may damage concentration-dependent control mechanism regulating allograft proliferation.

- 0226 POLYPEPTIDE CHAIN STRUCTURE OF IMMUNOGLOBULINS. II. ISOELECTRIC SEPARATION OF NORMAL AND MYELOMA IgG-GLOBULINS AND THEIR POLYPEPTIDES. (Ger.) Reis, H. E. (Clin. Intern. Med., Ruhr U., Essen, Germany), O. Wetter and T. Hake. *Klin Wschr* 48(14):862-866, 1970.

G-type immunoglobulins (IgG) and their light and heavy polypeptide chains from normal and myeloma sera were subjected to isoelectric focusing on a column provided with a combined pH and density gradient. IgG from normal sera separated into several heterogenous components (with multiple fractions) with isoelectric points ranging between pH 5 and pH 9 while IgG from myeloma sera separated into homogenous components (single fractions) with specific isoelectric points in the same range. Similar results were obtained by the fractionation of light and heavy polypeptide chains. While light and heavy chains from normal sera manifested considerable heterogeneity, the ones from myeloma sera appeared homogenous. Polyacrylamide-gel electrophoresis revealed no direct relation between isoelectric points and electrophoretic mobility. Quantitative amino-acid determinations, end group investi-

gations and other physical-chemical techniques revealed that amino acid distribution as well as protein conformation determined the differences of behavior of the light polypeptide chains.

- 0227 IMMUNOLOGY OF TROPHOBLASTIC TUMORS. (E.) Jakoubkova, J. (Oncol. Lab. Charles U., Prague, Czechoslovakia), A. Majsky, E. Ivaskova, M. Zavadil and V. Snajd. *Neoplasma* 17(3):223-229, 1970.

Serological studies were performed on 250 patients with trophoblastic diseases; patients were categorized as having benign trophoblastic disease (including benign trophoblastic invasion and mola hydatidosa) and malignant trophoblastic disease (including mola proliferans and chorioepithelioma). Sera of 69 and 32 women were examined for the presence of platelet and leucocyte antibodies. These antibodies were found in both above mentioned groups and were also present in sera of primiparous women without any transfusion in anamnesis. Platelet antibodies, mostly of the incomplete type, were found in 21 sera, cytotoxic leucocyte antibodies in 17 patients; their incidence in trophoblastic disease in comparison with that in healthy multiparous women was significantly higher. Examination of leucocytes of 15 women and their husbands for HL-A antigens revealed that 12 women were negative and 11 men were positive for the antigen Mac.

- 0228 DELAYED HYPERSENSITIVITY AND NEOPLASIA: *IN VITRO* STUDIES WITH MACROPHAGE MIGRATION. (E.) Steiner, T. (Mayo Grad. Sch. Med., U. Minnesota, Rochester) and A. L. Watne. *Cancer Res* 30(8):2265-2270, 1970.

Delayed hypersensitivity reactions of cells from rats bearing transplantable tumors was studied using an *in vitro* observation of macrophage migration. The reactions of peritoneal cells from tumor-bearing and normal animals were studied in extracts of homologous tumor, normal tissue, and specific antigen. Rats sensitized to tuberculin evidenced inhibition of cell migration when cultured in media containing purified protein derivative, and injection of 1.0, 10.0, or 20.0 million tumor cells s.c. 10 days prior to culture had no effect on this inhibition. Both normal rats and mice and those bearing transplantable tumors showed enhanced cell migrations when cultured in the presence of either normal tissue or pooled homologous tumor extracts. One group of rats were given injections of 1.0×10^6 tumor cells in the hindfoot, and after 10 days these legs were surgically removed. At that time or 2 weeks later, *in vitro* macrophage migrations were examined in the presence of extracts of the rat's own tumor, pooled tumor, and normal tissue. The rats showed enhanced cell migrations in extracts of normal tissue or pooled tumor; in extracts of the rat's tumor only, there was a tendency toward inhibition of cell migration. Tumor-bearing and normal rats evidently do not show any delayed hypersensitivity reaction to extracts of normal tissue or pooled tumor as evidenced by inhibition of macrophage migration *in vitro*. The enhanced cell migration observed in the 2 extracts is probably a non-immunological response.

- 0229 OBSERVATION OF IMMUNOGLOBULINS IN THE COURSE OF A TUMOR DISEASE. (E.) Dostalova, O. (Motol Hosp., Prague, Czechoslovakia), E. Schon, V. Kubelka and F. Holik. *Neoplasma* 17(3):231-240, 1970.

The method of simple radial diffusion in agar was used to examine the blood of 130 patients with breast, bronchial, laryngeal and other carcinomas for the purpose of observing the levels of the IgG, IgA and IgM immunoglobulins in their blood. Immunoglobulin levels were observed to vary in relation to the course of the disease, and in relation to the therapy used. The average levels of IgG and IgM were within the limits determined for the healthy population, while the IgA levels were higher than normal, particularly in patients in an advanced stage of disease. Eighty patients were examined repeatedly, and, in these, values for IgM and IgG were decreased as the course of the tumor disease advanced; in the same group, actinotherapy and cytostatic therapy had a depressing effect on the IgG level, while a stimulating effect on immunoglobulin level was produced by immunotherapy and hormone treatment by Agovirin.

- 0230 *IN VITRO* LYMPHOCYTE STIMULATION BY A SOLUBLE ANTIGEN FROM MALIGNANT MELANOMA. (E.) Nathanson, L. (New England Med. Ctr. Hosp., Boston, Mass.), U. W. Jehn, R. S. Schwartz and M. Skinner. *New Eng J Med* 283(7):329-333, 1970.

A soluble tumor antigen extracted from a cystic neoplasm in a patient with metastatic malignant melanoma was characterized and incubated with lymphocytes of 6 other melanoma patients. The tumor fluid contained an electrophoretic peak corresponding to β -globulin, which was separated from albumin, melanin, and γ -globulins by starch-block electrophoresis. The urine of this patient contained a peak with the same mobility, and gel diffusion studies using antisera to rabbit tumor fluid and urine revealed that both substances were antigenically identical. When tested in autologous lymphocyte cultures, the whole tumor fluid stimulated DNA synthesis; of the electrophoretic fractions only β -globulin fraction also stimulated DNA synthesis. The lymphocytes of the other 6 patients were stimulated when incubated with crude autologous tumor extract and when incubated with the tumor fluid of the first patient, although lymphocytes from normal patients did not respond to either tumor extracts or the tumor fluid.

- 0231 AGE DISTRIBUTION OF α -FETOPROTEIN IN HEPATOCELLULAR CARCINOMA. (E.) Bagshawe, A. (Dept. Med., U. Coll., Nairobi, Kenya) and A. M. Parker. *Lancet* 2(7666):268, 1970.

The influence of age on the occurrence of α -fetoprotein in patients with hepatocellular carcinoma and teratocarcinoma was investigated. α -Fetoprotein was detected in the serum of 15 of 24 patients with primary hepatic carcinoma, and correlation of the presence of α -fetoprotein with the age of the patients indicated that positive tests occurred mainly in younger patients (e.g., those under 30). Observed geographic variations in the occurrence of α -fetoprotein in hepatocellular carcinoma may

reflect the age-incidence of the tumor. Variation in the age at which the tumor occurs may indicate different etiological factors, but these need not directly influence α -fetoprotein production by the tumor.

- 0232 IMMUNOGLOBULIN (IgG, IgA AND IgM) LEVELS IN PRIMARY CARCINOMA OF THE LIVER AND CIRRHOSIS OF THE LIVER IN SINGAPORE. (E.) Chew, B. K. (Dept. Med., U. Singapore), M. Yu and R. Wee. *Med J Aust* 57(1):18-21, 1970.

The sera from 34 patients with carcinoma of the liver and from 36 cirrhotic patients were examined to determine the levels of the immunoglobulins IgG, IgA and IgM by the micro-double-diffusion agar method. In 65% of cases of primary carcinoma of the liver and in 83% of cases of cirrhosis the serum IgG level was elevated. IgA values were raised in 70% of cases of primary carcinoma of the liver and in 78% of cases of cirrhosis of the liver. No change was detected in IgM values, although in most of the cases of primary carcinoma of the liver the IgM values were well below the normal mean. The patterns of immunoglobulin levels in these 2 conditions were almost similar and therefore could not be used as a diagnostic aid.

- 0233 BONE MARROW SMEARS FROM CHILDREN WITH ACUTE LEUCOSIS: IMMUNOFLUORESCENCE MICROSCOPY. (Ger.) Hempel, H. C. (St. Child. Clin., Karl Marx St., Germany), J. Grimm and A. Tier. *Folia Haemat* 93(1):42-50, 1970.

Fluorescence microscopy of bone marrow smears from 12 children (10 with acute leucocytosis and 2 with acute myelosis) was performed on the following preparations: bone marrow smear, leukemic autologous serum and labeled Race-Coombs-serum; bone marrow smear and labeled leukemic autologous serum; and bone marrow smear and labeled Race-Coombs-serum. Control tests were made on bone marrow smears alone, bone marrow smears and dye solution, and bone marrow smears and labeled serum from healthy children. The dye used for serum globulin coupling was fluorescein isothiocyanate (FITC). Sera from the children were treated according to a modification of Coons et al by Koeditz and Wagner. Bone marrow smears of children with leucocytosis revealed a specific indirect fluorescence in 5 cases, a distinct direct specific fluorescence in 3 cases and a slight positive reaction in 2 cases. Positive reactions were obtained in only 1 of the 2 acute myelosis cases; all control tests were negative. Specific inhibition studies are needed to demonstrate the presence of antibodies in sera of patients with acute leukocytosis.

- 0234 CYTOLOGICAL STUDIES OF TUMORS: XLIX. CHRONIC LYMPHOCYTIC LEUKEMIA WITH A₁/G CHROMOSOME TRANSLOCATION AND HIGH SERUM γ -GLOBULIN PRODUCTION. (E.) Obara, Y. (Zool. Inst. Hokkaido U., Japan), S. Makino and C. Mikuni. *Cann* 61(1):1-6, 1970.

A 73-yr-old-male patient, diagnosed as a case of chronic lymphocytic leukemia, was found to have a

presumptive A₁/G translocation and an abnormally high serum γ -globulin content. In the blood culture, under the influence of phytohemagglutinin, mitosis of non-leukemic lymphocytes became predominant over that of leukemic lymphocytes with the A₁/G translocation, while A₁G cells comprised one-half of the metaphase population grown without phytohemagglutinin. At least 3 kinds of lymphocytes were present; leukemic lymphocytes with or without the A₁/G translocation dividing *in vitro* without phytohemagglutinin, and normal lymphocytes proliferating only under phytohemagglutinin stimulation. The amount of serum γ -globulin was extremely high in this patient. Analyses by immunoelectrophoresis and immunoplate revealed a striking increase of IgG. The A₁/G cells in the present case may or may not be related to the elevated γ -globulin production.

- 0235 POSITION OF THE CARCINOEMBRYONIC ANTIGEN OF THE HUMAN DIGESTIVE SYSTEM IN ULTRA-STRUCTURE OF TUMOR CELL SURFACE. (E.) Gold, P. (Montreal Gen. Hosp., Quebec, Canada), J. Krupey and H. Ansari. *J Nat Cancer Inst* 45(2):219-225, 1970.

The ultrastructural position of the carcinoembryonic antigen, a tumor-specific constituent of all adenocarcinomas arising from the endodermally derived epithelium of the digestive system, was localized on the surface of the tumor cell by electron microscopy and use of a ferritin-anticarcinoembryonic antigen conjugate. Normal colonic tissue samples incubated with the ferritin-antibody conjugate revealed no significant ferritin labeling under electron microscopy; in contrast, tumor cells exposed to the ferritin-antibody conjugate showed localization of ferritin primarily in the glycocalyx coating the cell surface membrane. The localization of carcinoembryonic antigen on the cell surface could explain the presence of the antigen in sera and stools of patients with cancer of the large bowel without presupposing the necessity of tumor tissue necrosis and subsequent absorption of released components.

- 0236 EFFECT OF PHYTOHEMAGGLUTININ AND PROSTAGLANDINS ON CYCLIC AMP SYNTHESIS IN RAT LYMPH NODE LYMPHOCYTES. (E.) Novogrodsky, A. (Weizmann Inst. Sci., Rehovot, Israel) and E. Katchalski. *Biochim Biophys Acta* 215(2):291-296, 1970.

The relationship between cyclic AMP and phytohemagglutinin action on lymphocytes was investigated. RNA and DNA synthesis in rat lymph node lymphocytes, both of which are stimulated by phytohemagglutinin, was only slightly enhanced or not affected by 10^{-5} - 10^{-8} M dibutyryl cyclic AMP; higher concentrations (10^{-4} M) were inhibitory. The rate of incorporation of labeled adenine into cyclic AMP in rat lymphocytes was unaltered as a result of incubation with phytohemagglutinin for 30 min. Prostaglandin E₁ markedly stimulated cyclic AMP formation in rat lymphocytes by enhancement of adenyl cyclase, but caused no cell transformations. Phytohemagglutinin (50 μ g/ml) had no effect on adenyl cyclase activity, confirming that rat lymphocyte transformation by phytohemagglutinin is not mediated by cyclic AMP.

37 THE *IN VITRO* TRANSFORMATION OF FROZEN-STORED LYMPHOCYTES IN THE MIXED LYMPHOCYTE REACTION AND IN CULTURE WITH PHYTOHEMAGGLUTININ D SPECIFIC ANTIGENS. (E.) Mardiney, M. R., Jr. (Baltimore Cancer Res. Ctr., Md.) and R. J. Mangi. *Exp Med* 132(3):401-416, 1970.

A study of the *in vitro* transformation of lymphocytes which have been frozen and stored at -60 C indicated that cells frozen at different times and stored for various times do transform in a reproducible manner when placed in culture with phytohemagglutinin, or as one population of the two-way mixed lymphocyte reaction. When frozen-stored lymphocytes are cultured with specific antigen or as both partners in the mixed lymphocyte reaction the response is minimal. The freezing process destroys neutrophils, and the remaining population transforms in a manner similar to cultures of purified lymphocytes. The transformation of frozen-stored human lymphocytes is a practical technique which warrants further investigation and practical application.

38 DNA REPLICATION IN ANTIGEN STIMULATED GUINEA-PIG LYMPH NODE CELLS. (E.) Souleil, (Inst. Pasteur, Paris, France) and J. Panijel. *Nature* 227(5257):456-460, 1970.

A replication was studied in primed guinea pig lymph node cells stimulated *in vitro* by homologous antigen (ovalbumin or hemocyanin) or by phytohemagglutinin. Deoxythymine, a density label which can be incorporated quantitatively into DNA, and ³H-bromodeoxyuridine were also added to the culture medium, and the labeled DNA, which represented the responsive cells, was separated on a CsCl gradient. The banding pattern of fragments of labeled DNA extracted from antigen-stimulated cultures was characterized by a bimodal distribution, but fragments from phytohemagglutinin-stimulated cultures showed only a single peak. Antigenic stimulation appears to trigger an alteration in the sequential replication of DNA corresponding to the series of genes involved in the physiological events underlying antibody synthesis.

39 LYMPHOCYTE TRANSFORMATION IN MALIGNANT LYMPHOMAS. (E.) Papac, R. J. (Yale U. Sch. of Med., New Haven, Conn.). *Cancer* 26 (2):279-286, 1970.

Peripheral blood lymphocyte cultures were established from 19 patients with malignant lymphomas, lymphosarcomas, and Hodgkin's disease to test the capacity of lymphoid neoplasms to respond to phytohemagglutinin; control subjects included both healthy and chronically ill subjects. A wide range of responsiveness to phytohemagglutinin was observed in cases of lymphosarcoma with a median transformation value for the group lower than that of control subjects (48% vs 60%). Correlation of lymphocyte transformation with phytohemagglutinin was noted with histologic type of lymphosarcoma, with duration of disease and with age of the patient. The most marked impairment of transformation generally occurred in patients with small cell lymphosarcoma, in patients

with brief duration of disease and older age groups. There was little correlation between peripheral blood lymphocyte level and percentage transformation with phytohemagglutinin. In patients with reticulum cell sarcoma, phytohemagglutinin stimulation was quite markedly impaired. Lymphocyte cultures from seventeen cases of Hodgkin's disease, which were included for comparison, showed impaired transformation with phytohemagglutinin (22%), which was related to stage of disease and peripheral lymphocyte levels.

- 0244 AMELOBLASTOMA: DELINEATION OF EARLY HISTOPATHOLOGIC FEATURES OF NEOPLASIA. (E.) Vickers, R. A. (U. Minnesota Sch. Dent., Minneapolis) and R. J. Gorling. *Cancer* 26(3):699-710, 1970.

Clinicopathologic data and material from 10 patients with cystic jaw lesions that manifested an apparently distinctive altered epithelium were analyzed and compared with published photomicrographs of early ameloblastomas, mural ameloblastoma, and examples of ameloblastoma arising in association with dental cysts. While the 10 specimens had all been considered cystic, 3 histopathologic alterations were consistently observed that delineated them from dental cysts. Histopathologic changes included: hyperchromatism of basal cell nuclei of the epithelium lining the cystic cavities; palisading and polarization of basal cell nuclei of the epithelium lining the cystic cavities; and cytoplasmic vacuolization of basal cells of cystic linings. Cystic lesions manifesting these histologic changes have been associated with ameloblastoma in a high percentage of instances.

- 0245 PAGET'S DISEASE OF THE VULVA -- A CYTOGENIC STUDY OF SKIN FIBROBLASTS, TUMOR CELLS, AND PERIPHERAL BLOOD LEUKOCYTES IN CULTURE. (E.) Mullick, S. (New England Med. Ctr. Hosp., Boston, Mass.), S. Bamford, G. W. Mitchell, Jr. and R. Gilfillan. *Acta Cytol* 14(7):404-410, 1970.

To investigate the hypothetical connection between chromosomal error and the onset of malignancy, cultured leukocytes, skin fibroblasts, and tumor cells from a patient with Paget's disease of the vulva were examined. A late replicating X chromosome in the large size range of the 6-X-12 (C) series was found in 57.5% of the leukocytes, while 66% of the vulvar skin fibroblasts showed a late replicating X chromosome in the small size range. A similar degree of hyperdiploidy between vulvar fibroblasts and tumor cells (19.3%) and skin fibroblasts of the forearm was observed after challenge with SV40 (20%) while striking differences in degree of hypodiploidy were observed in the same cultures (72% in the challenged cells as compared to 20% in the vulvar cells). Positive T antigen values (12.3% at 3 days and 11.6% at 8 days after challenge with SV40) were recorded in fibroblasts, indicating increased susceptibility to transformation of cells from a site distant to the tumor. The positive correlation of hyperdiploidy values found for unchallenged vulvar skin and tumor cells and the challenged fibroblasts from the forearm may indicate the existence of a mechanism within the cell (possibly reflected in the aberrant X) which renders it highly susceptible to transformation in the presence of an oncogenic agent.

- 0246 SERUM ALKALINE PHOSPHATASE AT THE ONSET OF HODGKIN'S DISEASE. (E.) Aisenberg, A. C. (Massachusetts Gen. Hosp., Boston), M. M. Kaplan, S. V. Rieder and J. M. Goldman. *Cancer* 26(2):318-326, 1970.

Serum alkaline phosphatase levels have been studied in 111 patients at the onset of Hodgkin's disease, and a correlation between elevated levels of the enzyme and the stage of the disease is reported. In Stages I and II, 14% of the patients had elevated enzymes, 65% in Stage III, and 87% in Stage IV. In all stages, a high incidence of elevated phosphatase was seen in patients with fever, but not in those with only pruritis, suggesting a different pathogenesis of the 2 complaints. The liver enzyme was elevated in 23/31 patients, it was not possible to state which enzyme was elevated. The majority of hepatic phosphatase increases were felt to be due to hepatic lymphoma, but several cases of a reversible liver isozyme elevation associated with fever and negative open liver biopsy were encountered. Infrequent elevations of bone phosphatase were seen in young patients with localized Stage I and II Hodgkin's disease; this elevation was considered to be a phenomenon of late adolescent bone growth and not due to osseous lymphoma.

- 0247 OCCURRENCE OF EPITHELIAL ATYPIA IN 51 INDIAN VILLAGERS WITH ORAL SUBMUCOUS FIBROSIS. (E.) Pindborg, J. J. (Royal Dental Coll., Copenhagen, Denmark), F. S. Mehta and D. K. Daftary. *Brit J Cancer* 24(2):253-257, 1970.

Biopsies were performed on the oral mucosa of 51 Indian villagers with oral submucous fibrosis to explore the suggested precancerous nature of oral submucous fibrosis. When sections were examined for epithelial atypia, marked atrophy of the epithelium was found in 71.7% of sections, in which the atrophic epithelium showed no rete ridges. The normally unkeratinized buccal mucosa revealed either ortho- or parakeratosis or hyperortho- or hyperparakeratosis in 48.0%. In one patient the histologic examination disclosed a squamous cell carcinoma. In 22.6% of the biopsies an epithelial atypia was found. Features commonly associated with epithelial atypia included irregular epithelial stratification and increased numbers of mitotic figures. The hypothesized premalignant nature of these atypias is supported by the observation of a squamous cell carcinoma developing in an oral mucosa section changed by submucous fibrosis and by the observation that atypia is often found adjacent to carcinomas that develop in patients with submucous fibrosis.

- 0248 CERVICAL CONE BIOPSY ON THE NORMAL-LOOKING CERVIX WITH ABNORMAL CYTOLOGY. (E.) Slabber, C. F. (Dept. Obstet. Gynec., U. Stellenbosch, Union of South Africa) and J. N. De Villiers. *S Afr J Obstet Gynec* 8(1):36-39, 1970.

The incidence of early cervical cancer in patients with an apparently normal cervix, but abnormal cytology, was studied in a series of patients subjected to cervical cone biopsy. In a 3 yr period, cone biopsy showed that 62% of patients with normal-looking cervix and abnormal cytology had early cervical cancer, including the following pathological diagnoses: carcinoma *in situ*, micro-infiltrating carcinoma, and infiltrating carcinoma. No age

group was free of early cancer; however, micro-infiltrating carcinomas generally occurred at a later age than carcinoma *in situ* (average age of 36.4 and 34.7 yr, resp.). Nulliparity did not render patients immune to early cervical cancer.

49 POLYGONAL CRYSTALLINE STRUCTURES IN HUMAN EPENDYMOMA CELLS. (E.) Tani, E. (Kyoto U. Med. Sch., Japan) and T. Ametani. *Acta Neuropath* (4):359-362, 1970.

Electron microscopic examination of human ependymoma cells revealed polygonal crystalline structures which were situated mainly in the lysosomes. These structures, which were clearly distinguishable from the amorphous matrix of the lysosomes, consisted of a regular spacing (150-160 Å) of alternating dense and less dense layers and had one to three axes of linear densities. The individual dense and less dense layers formed a rectilinear array in one crystalline axis, a tetragonal array in two axes, and a hexagonal array in three axes.

50 INVASION OF CARTILAGE BY AN EXPERIMENTAL RAT TUMOR. (E.) Poole, A. R. (Strangeways Res. Lab., Cambridge, England). *Cancer Res* 30(12):2252-2259, 1970.

The Guerin T8 epithelioma was transplanted into female rats for the purpose of studying the *in vivo* invasion of cartilage of the xiphisternum by malignant tumors. Staining of cartilage with toluidine blue was considerably reduced or absent at the edge of the invading tumor. Frequently, matrix staining around chondrocytes close to the tumor was much more intense than that of more remote matrix. This pericellular staining feature was also observed in cartilage from tumor-free animals treated with papain. It was absent from those which received an excess of vitamin A. Appreciable intercellular β -glucuronidase activity was observed in tumor-infiltrated cartilage, but not in normal cartilage. In chondrocytes, this enzyme was normally observed in all cytoplasmic particles (0.2-0.5 μ in diameter). The presence of the established tumor, however, larger stained particles (1.0-2.0 μ in diameter) were frequently observed. The rate of lysosomal staining for acid phosphatase was unchanged in chondrocytes and fibroblasts of cartilage undergoing early tumor infiltration, but was increased in later stages. Inasmuch as β -glucuronidase was present in the matrix ahead of the invading tumor, the results of the study suggest that lysosomal enzymes are present extracellularly in *in vivo* degradation by tumors.

51 A HISTOCHEMICAL STUDY ON THE HISTOGENESIS OF THE MIXED TUMORS OF THE HUMAN SALIVARY GLANDS. (E.) Mira, E. (Inst. Compar. Anat., U. Pavia, Italy) and I. Vidi. *Acta Histochem* 36(2):199-398, 1970.

The histogenesis of 12 neoplasms in the human parotid, submaxillary and minor salivary glands was studied. The homogeneous material contained in the duct-like cavities of the epithelial areas contain neutral epithelial mucins and, in a lesser quantity,

sialomucins and sulphomucins, also of epithelial origin; the intercellular substances of the myxoid and chondroid areas showed the histochemical properties of the connective tissue mucopolysaccharides, hyaluronic acid and chondroitin sulfate 4 and/or 6. In particular, histochemical evidence suggests that the intercellular substance of the myxoid and chondroid areas of the mixed tumors is of a connective nature, and contrasts with the hypothesis of their production by epithelial or myoepithelial neoplastic cells.

0252 CELL SURFACE COATINGS AND MEMBRANE POTENTIALS OF MALIGNANT AND NONMALIGNANT CELLS. (E.) Hause, L. L. (Marquette Sch. Med., Milwaukee, Wisc.), R. A. Patillo, A. Sances, Jr. and R. F. Mattingly. *Science* 169(3945):601-603, 1970.

Single cells from malignant and non-malignant cell cultures were impaled with microelectrodes for bioelectrical recordings of the electrically charged sialomucin cell coating. Positive electrical prepotentials, which ranged from 1-8 mv which increased with the pH of the cell, were recorded in all malignant cells studied. Normal human trophoblasts and lymphocytes also exhibited positive prepotentials, whereas other normal cells studied rarely gave prepotential readings. The finding of a prepotential associated with a surface constituent of malignant cells suggests the presence of a cell surface coating of an ionic nature.

0253 INVASIVE TUMOR GROWTH: COMPARATIVE HISTOLOGY AND ELECTRON MICROSCOPY, HISTOCHEMISTRY AND BIOCHEMISTRY. VI. HISTOCHEMICAL STUDIES OF BRAIN MYELIN SHEATH LIPIDS DURING TUMOR INFILTRATION. (Ger.) Rath, F. W. (Path. Inst. Martin Luther U., Wittenberg, Germany), U. Bonk, C. Coutelle, R. Coutelle, D. Felicetti and F. Traub. *Acta Histochem* 36(1):64-73, 1970.

Invasive tumor infiltration was studied in 82 brain tumors in mice induced by inoculation of Ehrlich ascites carcinoma. Medullary infiltration began along the capillaries; tumor cell expansion continued within the medulla, gradually dividing the medullary substance into stripes and islets; medullary lipids were still detectable within the tumor cell. Sudden solubilization of sheath fragments between the tumor cells occurred later, and fatty traces resulting from myelin breakdown were barely detectable. Final medullary breakdown within the tumor occurred in the immediate vicinity or within necrotic areas, which were characterized by high levels of unsaturated hydrophobic lipids and cholesterol esters and were considered to be the main source of hydrolytic enzymes. Visible myelin breakdown occurred within the marginal tumor zones, while the tumor cells remained unaltered.

0254 CHROMOSOMES OF ADENOCARCINOMA OF THE CERVIX UTERI WITH A RING AND A MINUTE MARKER CHROMOSOME. (E.) Salimi, R. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and H. W. Jones, Jr. *J Surg Oncol* 2(1):17-22, 1970.

Biopsy studies of the chromosomes of an adenocarcinoma of the cervix uteri were performed by a direct squash method, with the result that a modal number of about 40 chromosomes was obtained from the differentiated portion of the tumor. A ring chromosome and a minute chromosome were seen in 58% of the hypodiploid cells. The undifferentiated part of the tumor showed marked anaplastic activity and hyperchromatism with large heavily stained and multiple nuclei with chromatin condensation and clumping, but with little evidence of mitosis; no successful chromosome preparations could be made from this portion of the tumor.

0255 THE NATURE OF PARTICULATE THYROID PROTEINS IN AN EXPERIMENTAL RAT THYROID TUMOR. (E.)

Salabe, G. B. (2nd. Med. Clin., U. Rome, Italy) and J. Robbins. *Biochim Biophys Acta* 214(1):198-206, 1970.

The nature of microsomal particulate proteins labeled with ^{14}C -leucine or ^{125}I in an experimental rat thyroid tumor able to incorporate ^{125}I into soluble thyroglobulin was investigated. A large proportion (20-50%) of the radioactivity, either ^{14}C or ^{125}I , was particulate and associated with the nuclear or microsomal pellets. When proteins released by deoxycholate from microsomes were analyzed by density gradient centrifugation and tested with a rabbit anti-rat thyroglobulin serum, 60% of the proteins labeled with ^{125}I and 30% of those labeled with ^{14}C had a sedimentation rate of 12 S; the latter reacted with anti-thyroglobulin serum. Density gradient centrifugation patterns of soluble proteins labeled with ^{14}C or ^{125}I for 30 min-18 hr showed that ^{125}I is incorporated into 19-S thyroglobulin, whereas no more than 10% of ^{14}C -leucine was found in the 19-S protein. The remaining 80-90% of the radioactivity had a sedimentation rate of 3-8 S. Microsomes of rat thyroid tumor appear to contain a large proportion of thyroglobulin or its precursors; a deficiency in the mechanism for release of protein from the endoplasmic reticulum may account for the minimal presence or absence of soluble thyroglobulin.

0256 TURNOVER OF MAMMALIAN PHOSPHOLIPIDS: STABLE AND UNSTABLE COMPONENTS IN NEOPLASTIC

MAST CELLS. (E.) Pasternak, C. A. (Dept. Biochem., U. Oxford, England) and J. J. M. Bergeron. *Biochem J* 119(3):473-480, 1970.

Exponentially growing or static neoplastic mast cell cultures were labeled with ^{14}C -choline and ^{14}C -inositol to investigate the phospholipid turnover process; protein and DNA turnovers were also monitored with ^{14}C -valine and ^{14}C -thymidine. Phospholipid turnover followed a biphasic pattern, the unstable rapidly turning-over component accounting for 60-80% of labeled phospholipid. The residual stable component did not turn over any more than did protein or DNA. Subcellular fractions and surface membranes of choline-labeled neoplastic cells contained the same proportion of stable and unstable components as did whole cells. The unstable component was largely phosphatidylcholine; the stable

component was relatively richer in sphingomyelin. There appears to exist 2 classes of phospholipids in neoplastic mast cells, one of which is metabolically stable, and the other which is subject to continual enzyme degradation and resynthesis; the turnover of the unstable component is apparently independent of cell growth, since the rate of incorporation of label was the same for the exponential and stationary phase cells.

0257 CYTOCHEMICAL DEMONSTRATION OF ACID PHOSPHATASE AND NON-SPECIFIC ESTERASES AS A MEANS OF IDENTIFICATION AND ESTIMATION OF DIFFERENTIATION OF HUMAN LYMPH NODE CELLS. (E.) Pruska-Koepe, H. (Med. Acad. Lodz, Poland). *Folia Histochem Cytochem* 8(2):159-176, 1970.

Fifteen human lymph nodes were examined, 3 of which were affected by hyperplastic diseases including lymphoblastoma, reticulosarcoma and lymphogranulomatosis maligna; the activity of acid phosphatase and non-specific esterase in these tissues was studied histochemically. A strong activity of both enzymes was present in reticuloendothelial cells, but absent from lymphatic cells. In malignant hyperplastic diseases of the lymph nodes the number of the reticular cells of the youngest and intensely non-specific esterase-positive generations markedly increased. In lymphoproliferative diseases the type of cells subject to neoplastic transformation affects the enzymatic activity of reticulo-endothelial cells.

0258 PLASMA MEMBRANES: THEIR ATPASE ACTIVITY AND ROLE IN CARCINOGENIC MECHANISM. (E.)

Raikhlin, N. T. (Acad. Med. Sci., Moscow, USSR). *Folia Histochem Cytochem* 8(2):117-120, 1970.

ATPase activity and its localization were investigated in an electron microscopic and histochemical study of the plasma membranes of liver parenchyma cells of normal and hepatoma-bearing adult mice. In the plasma membrane of a neoplastic cell there was either disappearance or a striking suppression of the functional heterogeneity of different membrane regions. The heterogeneity was demonstrable in the normal liver parenchyma cell subjected to the histochemical reaction for ATPase activity. Weakening and, in individual regions, loss of the ability to derive energy from ATP was observed in neoplastic cells. A change in the nature of energy production on the neoplastic cell surface may underlie many manifestations of specific traits of the neoplastic cell, and may be either the cause or a result of a shift in functional interrelationships of subcellular structures.

0259 ELECTRON MICROSCOPIC STUDIES OF THE ATPASE ACTIVITY IN THE NUCLEI OF NEOPLASTIC AND NORMAL LIVER PARENCHYMA CELLS OF MAN AND OF EXPERIMENTAL ANIMALS. (E.) Raikhlin, N. T. (Acad. Med. Sci. USSR, Moscow) and A. S. Shubin. *Folia Histochem Cytochem* 8(2):121-128, 1970.

Transplantable mouse hepatomas and normal mouse liver were examined by electron microscopy to investigate

the localization of ATPase in the nuclei of normal and neoplastic cells. ATPase was localized in all the main structural components of the interphasic nucleus: nucleolus, interchromatinic granules, chromatin, and nuclear membrane. However, the localization of the enzyme in normal cells was somewhat different from that in neoplastic ones: in the nuclear membranes of the latter (in the given experimental conditions) ATPase was almost non-demonstrable. However, the nuclear membrane of the neoplastic cells had lost ATPase, or was unable to manifest its activity in the given experimental conditions, perhaps because of the demonstrated different capacities of the nuclear membranes of normal and neoplastic cells to hydrolyse ATP and consequently to release the energy in this compound on the nuclear surface; this difference may underlie considerable differences in the structural-functional organization of the nuclei and in nucleo-cytoplasmic interactions in the cell types. The nuclear chromatin-bound ATPase of the cancer cell appears to differ in some properties from the earlier recognized ATPases A and B. Furthermore, it may be that ATPase in any structural component of the nucleus changes independently of its localization in other nuclear regions, this being indicative of a certain autonomy in cancer cells. Cancer cells from human liver are approximately identical to cancer cells from experimental animals' liver with respect to nuclear localization of ATPase.

60 AGE DIFFERENCES IN THE HISTOLOGY OF HODGKIN'S DISEASE. (E.) Newell, G. R. Tulane Sch. Publ. Hlth. Trop. Med., New Orleans, La., S. R. Cole, O. S. Miettinen and B. MacMahon. *Nat Cancer Inst* 45(2):311-317, 1970.

ix histologic features of Hodgkin's disease (eosinophilia, atypical mitoses, areas of preserved architecture, extent of disease, Reed-Sternberg cells and extent of fibrosis) reviewed for 284 cases were rated according to severity between 0 and 4; discriminant function score calculated for these features was found to differ strikingly between patients aged 15-35 yr and those aged above 50 yr. Patients with scores less than 5 comprised only 4% of those aged 15-34 yr, but 32% of those aged over 50 yr; the percentages of scores above 15 were 49% and 8%, resp. The distribution of scores for the 15-34 yr age group were 26% for scores under 5 and 74% for scores over 15. The relationship of individual histologic features to a representative series of patients of all ages suggest that at least 2 etiologic entities might be distinguished on the basis of age of onset, 15-34 yr or over 50 yr. Patients in the age group 35-49 yr are probably a mixture of the histologic types comprising the other 2 age groups.

61 POORLY DIFFERENTIATED SUBENDOTHELIAL CELLS IN SWINE AORTAS. (E.) Lee, K. T. (Albany Med. Coll., N. Y.), K. J. Lee, S. K. Lee, H. Imai and M. O'Neal. *Exp Molec Path* 13(1):118-129, 1970.

Eleven pigs maintained for 3 days on a hyperlipemic diet were sacrificed, and the poorly differentiated masses of smooth-muscle cells in the intima of their aorta

induced by this diet were examined by electron microscopy. Because of the location of these lesions in the intima, it was possible that a special subpopulation of subendothelial cells was the origin of the cell masses. A study of 385 poorly differentiated cells lying in the intima of the aortic trifurcation of swine revealed that most of these cells were in close apposition to the endothelium, and that their incidence was approximately 7/100 endothelial cells. By using subjective morphologic criteria, the cells were divided into 3 groups: smooth-muscle cell-like, 30%; monocyte-like, 40%; and unclassified, consisting of cells without specialized features, 30%. The hyperlipemic diet produced no effect on the frequency and fine structure of these cells.

0262 CYTOLOGIC DIAGNOSIS OF MAMMARY TUMORS FROM ASPIRATION BIOPSY SMEARS: COMPARISON OF CYTOLOGIC AND HISTOLOGIC FINDINGS IN 2,111 LESIONS AND DIAGNOSTIC USE OF CYTOPHOTOMETRY. (E.) Zajicek, J. (Karolinska Hosp., Stockholm, Sweden), T. Caspersson, P. Jakobsson, J. Kudynowski, J. Linsk and M. Us-Krasovec. *Acta Cytol* 14(7):370-376, 1970.

- 0264 AGE-ADJUSTMENT OF INCIDENCE RATES IN CANCER EPIDEMIOLOGY. (E.) Hakama, M. (Finnish Cancer Registry, Helsinki). *Acta Path Microbiol Scand* (suppl. 213):1-47, 1970.

The most useful comparisons of disease frequency in different areas and in different population groups are made by incidence rates of the disease. These rates have been adjusted in order to eliminate the confounding effects of concomitant variables, the most common of which is age. A parametric statistical method age-adjustment is proposed and the biological basis of this procedure in the case of cancerous diseases is outlined. It is proposed that the Gaussian curve approximates the incidence curve for which the age specific incidence rates are discrete estimates. The information included in the specific rates cannot be replaced by a single index. The proposal that the probability of occurrence of a tumor by a given age has a normal distribution leads to 3 indices, maximum value, mean and standard deviation of the incidence curve, which specify cancer incidence by age. The parametric method is applied to 4 different primary sites of cancer: stomach, lung, nervous system, and breast. The proposed method of adjustment applies only in cancerous diseases with age as the confounding variable.

- 0265 EPIDEMIOLOGICAL CHARACTERISTICS OF BREAST CANCER IN MIDDLE AND LATE AGE. (E.) Hems, G. (U. Med. Building, Foresterhill, Aberdeen, Scotland). *Brit J Cancer* 24(2):226-234, 1970.

Data for different countries were examined for associations between breast cancer rates at 40-44 yr and at 65-69 yr with diet, parity, birth rate and blood group, with the result that a positive correlation between breast cancer and sugar and fat intakes was found. The correlation explained three-quarters of the variation in the "late rate" (65-69 yrs), for 22 countries, but only half of the variation in the "early rate" (40-44 yrs). The late rate was, further, positively correlated with estimates of the percentage of nulliparous women (9 populations) and, together with terms for sugar and fat intakes, the multiple regression explained 90% of the variation. Early registration rates (13 populations) were positively correlated with blood group A which appeared, from the multiple regression equation, to contribute more than twice the amount to the early rate than did sugar and fat intakes. The contribution of blood group A to the late rate appeared to be only one-third of that for sugar and fat intakes. The results may indicate that the late breast cancer rate was influenced by environmental factors of food and diet and by factors associated with childbirth, whereas the crucial factor influencing the early rate was a constitutional factor, blood group A.

- 0266 MULTIPLE MYELOMA: A COMMUNITY CLUSTER. (E.) Kyle, R. A. (Mayo Clin., Rochester, Minn.), L. Herber, B. L. Evatt and C. W. Heath, Jr. *JAMA* 213(8):1339-1341, 1970.

Six cases of multiple myeloma were diagnosed among residents of Thief River Falls, Minnesota (popula-

tion 7,151) during 1968. This is a rate of 84 per 100,000, as compared with an expected rate of about 3 per 100,000. The clinical and laboratory features of these cases were typical of myeloma; in addition one case of Waldenström's macroglobulinemia was found during this period. The incidence of other forms of leukemia and lymphoma and of congenital malformation was not increased in the town during the years 1960 through 1968. None of the 6 myeloma patients shared a common association apart from their residence in the same town. The cause of this apparent community cluster of multiple myeloma cases remains obscure.

- 0267 GEOGRAPHIC ASPECTS OF MALIGNANT LYMPHOMA AND MULTIPLE MYELOMA: SELECT COMPARISONS INVOLVING JAPAN, ENGLAND, AND THE UNITED STATES. (E.) Anderson, R. E. (U. New Mexico Sch. Med., Albuquerque), K. Ishida, Y. Ii, T. Ishimaru and H. Nishiyama. *Ame J Path* 61(1):85-97, 1970.

Application of Western diagnostic technics to Japanese case material for reticulum cell sarcoma, lymphosarcoma and Hodgkin's disease indicate that only some of the differences between the relative prevalence of these conditions in Japan and in the United States and England can be explained by discrepancies in classification and/or histologic interpretation. Reticulum cell sarcoma is the most prevalent form of malignant lymphoma in Japan with a relative frequency (42%) that approaches Hodgkin's disease in Western series (49%). Conversely Hodgkin's disease is the least frequently encountered form of lymphoma in Japan with a relative frequency (20%) not far removed from reticulum cell sarcoma (11%) in the West. There is little difference in relative prevalence of lymphosarcoma in Japanese and Western experience. Finally, each type of lymphoma in Japan appears to be associated with a shorter estimated clinical course than the comparable disease in the United States. Discrepancies in host reactivity, which are probably genetically governed, may account for those geographic differences in prevalence of malignant lymphomas.

- 0268 EPIDEMIOLOGY OF PRIMARY MALIGNANT MESOTHELIAL TUMORS IN CANADA. (E.) McDonald, A. D. (Dept. Epidem. Hlth., McGill U., Montreal, Quebec, Canada), A. Harper, O. A. El Attar and J. C. McDonald. *Cancer* 26(4):914-919, 1970.

A compilation made of all fatal malignant mesotheliomas reported in Canada between 1959-1968 revealed 165 tumors, 66% of which occurred in males. Sites of mesothelial malignancy location included the pleura, peritoneum and pericardium. Occupational and residential histories were obtained "blind" from relatives and friends of 90% of the cases and 2 matched control series. An association with definite or probable occupational exposure to asbestos was clearly demonstrated in 20% of the male cases and one female case. Almost all the excess was in the manufacture and industrial application of asbestos rather than in mining or milling. This result suggests that chrysotile is less associated with mesothelial tumors than other forms of asbestos, or that some other factor is also required for

s carcinogenic effects. No association was found with lesser degrees of occupational exposure or residence in asbestos and mining areas, but there was a small excess of possible domestic exposures. The smoking histories in the mesothelial tumor and main control groups were almost identical and unlike those for cases of primary lung cancer. In 9 cases of mesothelial tumor, an occupational exposure to copper, nickel, rubber, or fiberglass was noted.

59 THE EPIDEMIOLOGY OF SKIN CANCER IN QUEENSLAND: THE INFLUENCE OF PHENOTYPE AND ENVIRONMENT. (E.) Silverstone, H. (U. Queensland Med. Sch., Brisbane, Australia) and J. H. A. Searle. *Int J Cancer* 24(2):235-252, 1970.

A multivariate statistical analysis was performed on data on residents of 3 separate areas of Queensland, Australia, to determine the influence of age, sex, susceptibility to sunburn, complexion, eye color, ancestry, occupation, clothing habits and residential area on the etiology of skin cancer and solar keratoses. For both sexes, both diseases and all age groups the susceptibility to sunburn factor proved to be the most important single factor, once the age effect had been removed. On the whole it appeared that the genetically based factors as a group provided more information on susceptibility than the environmental factors. The relative importance of "occupation" remains in some doubt; in the tropical area away from the coast it appears to be of considerable importance, whereas in coastal areas its influence appears to be blunted, presumably by factors such as outdoor sports and recreation habits, which increase the exposure to sunlight of outdoor workers.

70 ON THE FREQUENCY OF LEUKEMIAS AND RELATED DISEASES: AN EVALUATION OF THE BAVARIAN VITAL STATISTICS: 1932-1964. (Ger.) Ambs, E. (Child. Clin., Wurzburg, Germany) and E. Jansen. *Munchen Med Wschr* 112(32):1453-1465, 1970.

An examination of the figures on mortality from leukemia and aleukemia as well as other neoplasms of the lymphatic and hematopoietic organs in Bavaria compiled between 1932-1964 revealed that the incidence of leukemia has increased slightly among persons between 1-5 yr old. However, a clear-cut increase was conspicuous only in age groups from 45-50 yr, and the older the patients, the more increased of leukemia. The rapid increase in leukemia mortality in the elderly is apparently due to an increase in leukemia incidence, rather than to an increase in the proportion of older people. Males showed a higher mortality from leukemia than females, a tendency which became more marked with increasing age.

71 SOME EPIDEMIOLOGICAL FEATURES OF HODGKIN'S DISEASE IN JAPAN. (E.) Nishiyama, H. (Nagoya Cancer Ctr. Res. Inst., Nagoya, Japan) and T. Sue. *Gann* 61(3):197-205, 1970.

A analysis of the mortality rates of age-specific groups, for Hodgkin's disease in Japan, showed a

distinct difference in the 2 age groups observed. Decreasing mortality rates in the young and increasing rates in the elderly with a minor difference in the changing pattern between the sexes were seen. Male predominance was the expected finding through all age groups, while pronounced death rates in the young was not a feature in Japan, and no bimodal curve was observed by examining age distribution in cases dying from Hodgkin's disease. Male-to-female mortality ratios appeared consistently similar in all age groups through 2 different study periods of 1950-58 and of 1959-66. There are marked variations in mortality rates for the 9 districts of Japan, and these seem not to be derived from the difference of diagnostic criteria in each district. The low rate of mortality in large cities like Tokyo and Osaka was unexpected and has not been reported previously.

0272 THE GEOGRAPHICAL DISTRIBUTION OF HODGKIN'S DISEASE AND ITS URBAN/RURAL RATIO IN NORTHERN GERMANY. (Ger.) Dorken, H. (1st Med. U. Clin. Hamburg, Germany), R. Fliessbach and H. Buss. *Z Krebsforsch* 74(2):190-199, 1970.

Between 1964 and 1965, 344 deaths from Hodgkin's disease were recorded in Northern Germany. The age-adjusted death rates of 2.2 per 100,000 inhabitants per year (male) and 1.6 (female) in Hamburg were similar to the known values of other European countries. The rates for Schleswig-Holstein and Niedersachsen, however, were somewhat lower (1.6-1.2 and 1.6-1.4), probably due to failure to diagnose correctly cases in the higher age-groups in these predominantly rural districts. The range of the death rates in the 101 counties investigated (from 0.0 to 7.0 per 100,000 per year) could easily be accounted for by chance variation for relatively small numbers. No evidence of clustering of cases in time and space was seen. Age-adjusted death rates from Hodgkin's disease were approximately equal in urban and rural districts in Northern Germany in both sexes, in contrast to nearly all other neoplasms. However, detailed analysis of age-specific rates showed a slightly higher rate for younger males in rural areas, suggesting the existence of exogenous factors in the rural environment (occupation or animal contacts).

0273 SOFT PART SARCOMAS IN NEGROES. (E.) Leffall, LaS. D., Jr. (Freedmen's Hosp., Washington, D. C.), M. Crawford, E. B. Chung and J. E. White. *Cancer* 26(3):503-512, 1970.

The incidence and pathological distribution of soft somatic tissue sarcomas were studied in 59 Negro patients; sarcomas were classified as: angiosarcoma; extraosseous chondrosarcoma; dermatofibrosarcoma protuberans; fibromatoses (extra-abdominal desmoids); abdominal desmoids; fibrosarcoma; liposarcoma; leiomyosarcoma; myxosarcoma; malignant neurilemmoma; rhabdomyosarcoma, and synovial sarcoma. Fibrosarcoma and dermatofibrosarcoma protuberans were observed in 52% of the patients, with the lower extremity being involved most often (24 patients). Females predominated with a sex ratio of 2:1; associated incidental findings were essen-

tial hypertension (34%) and diabetes mellitus (12%). Blood borne metastases were most frequent, but lymph node metastases also occurred. Angiography was of adjunctive value in 2 patients. Biopsy (incisional or excisional) and treatment by wide local excision, muscle group excision, or amputation were mainstays in management. With exception of desmoids and dermatofibrosarcoma protuberans, 5-yr survival was quite low. Negroes appeared to have a greater number of fibrous tissue tumors than other populations studied.

- 0274 REAPPRAISAL OF BASAL CELL CARCINOMA OF THE EYELIDS. (E.) Blodi, F. C. (U. Hosp., Iowa City, Iowa) and A. L. Aurora. *Amer J Ophthalmol* 70(3):329-336, 1970.

A survey of 172 cases of basal cell carcinoma of the eyelids revealed that the "solid" morphologic type of carcinoma made up 68% of cases, and that this type had an incidence in males twice as high as its incidence in females, whereas the adenoid variety of tumor occurred more often in females than in males. Below the age of 50 yr, basal cell carcinoma of the eyelids seemed to be distributed evenly between men and women; thereafter, however, many more males were affected than females. In females, the condition is apt to have its onset from 6-10 yr earlier than in males, although there is apparently no notable difference in duration of symptoms in the 2 sexes. Circumscribed lesions were more frequent in the lower eyelids, while extensive lesions more often affected the inner canthus. Data on cause of death were available for 68 patients; of these, 9/13 died of malignant diseases other than basal cell carcinoma.

- 0275 SEX MORTALITY RATIOS IN LEUKEMIA. (E.) Nishiyama, H. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan). *Cann* 61(3):263-266, 1970.

The changing patterns of sex mortality ratios for leukemia observed between 1947 and 1966 in Japan are presented. As in the United States and the United Kingdom, a male predominance of leukemia mortality was found for all ages and was most marked in those over 55 yr. Sex mortality ratios decreased in all age groups in Japan during the study period. The predominant type of leukemia among the Japanese is acute granulocytic leukemia, whereas chronic lymphocytic leukemia predominates in Europe. In Japanese leukemia victims over 75-yr-old, the mortality ratio for men is more than twice that for women. This variance may be associated with the fact that elderly Japanese women are more likely than men to be confined to their homes and therefore incur less risk of exposure to leukemia. An increasing rate of female employment in Japan may result in a decrease of male predominance in death rates among the over 55 age group.

- 0276 AN EPIDEMIOLOGIC STUDY OF AN OIL MIST EXPOSURE. (E.) Goldstein, D. H. (New York U. Med. Ctr., New York), J. N. Benoit and H. A. Tyroler. *Arch Environ Hlth* 21(5):600-603, 1970.

A fifteen year mortality study was performed on a group of newspaper pressmen who were occupationally

exposed to a mineral oil mist, and on a control group of compositors who were not so exposed. Although animal experiments have produced lipid granulomas in dogs exposed to petroleum base mineral oil, no significant difference in respiratory mortality or morbidity was encountered. This was supported by particle size determinations which showed more than 85% of the oil droplets were collected by a sampler which showed a 50% cut at 3.5 μ aerodynamic diameter. The respirable fraction was less than 5 mg/cu m. The control group of compositors showed a higher incidence rate of pulmonary carcinomas than the test group.

- 0277 COMPARISON OF AGE, SEX AND INCIDENCE RATES IN HUMAN AND CANINE BREAST CANCER. (E.) Schneider, R. (California St. Dept. Publ. Hlth., Berkeley). *Cancer* 26(2):419-426, 1970.

Since the essential ovarian and anterior pituitary hormones function in a similar manner in the reproductive cycle of man and dog (whereas spontaneous ovulation does not occur in the mouse and rat), a comparison of a 5-yr collection of cases of human breast cancer in males and females from the Alameda County Tumor Registry and a 5-yr collection of canine cases from the Alameda-Contra Costa Counties Animal Neoplasm Registry was made to determine if the pattern of the disease was the same in both. When ages of dogs were converted to human equivalents and canine and human incidence were adjusted to the same population distribution, canine age-adjusted incidence rates were 3 times higher in females and 16 times higher in males. Female age-specific rates increased at the same magnitude for both species until the start of the ages of natural menopause in women; then the human rates continued to increase more slowly, while the canine rates continued to increase at approximately the same exponential value as in the younger age group. A sparing effect on mammary cancer risk for bitches neutered before the age of 2½ yr and a similar decrease in breast cancer risk in women undergoing artificial menopause under 40 yr suggest that enough similarity may exist between man and dog to gain useful information about the etiology of breast cancer from study of dogs.

- 0278 SPACE-TIME CLUSTERING OF CHILDHOOD LEUKEMIA IN SAN FRANCISCO. (E.) Klauber, M. R. (U. Utah Coll. Med., Salt Lake City) and P. Mustacchi. *Cancer Res* 30(7):1969-1973, 1970.

The hypothesis that the incidence of leukemia clusters in space and time was tested by the application of Mantel's regression approach to the records of time of diagnosis and address of 149 leukemia cases diagnosed in San Francisco between 1946 and 1965. The cases were partitioned into consecutive time intervals, and the sum of the distances between pairs of cases falling within intervals was compared to its expectation, assuming a random allocation of space points to time points. Five different interval sizes were used: 0.5, 1, 2, 4, and 12 months. The 2-month intervals were chosen in advance for significance testing purposes at the 5% level. Separate analyses were performed for

ages 0 to 14 and 2 to 14 years. Neither of the age groupings showed statistically significant clustering for 2-month intervals. The only analysis of this same type yielding a p value less than 0.05 was for ages 2 to 14 years and with 12-month intervals ($p = 0.024$). A comparison of "within" time interval average distance between cases to "between" time interval average distance indicated that "clustering" in the series was weak. A single analysis of a case series with a long time span appears to be subject to artifactual space-time clustering occurring in the population at risk.

0279 CANCER STATISTICS, 1970. (E.) Silverberg, E. (Amer. Cancer Soc., New York, N. Y.) and R. N. Grant. *CA* 20(1):10-23, 1970.

Mortality statistics, morbidity statistics, and survival rates related to cancer in the United States show that cancer is the second leading cause of death in the nation (720,892 deaths in 1967), with crude mortality from cancer of the lung and pancreas and from leukemia having increased steadily in both sexes since 1930 (from 2.5 to 42 male deaths per 100,000 population for lung cancer). Mortality from uterine cancer has decreased in females (from 27 to 11 deaths per 100,000 population), and mortality from cancer of the stomach and liver has decreased in both sexes. The increase in mortality from cancer of the pancreas and from leukemia has been slow, while the increase in mortality from lung cancer has been rapid. Morbidity statistics indicate that of 525,000 new cancer cases in the United States, skin cancer (112,000 new cases), lung cancer (68,000 new cases), cancer of the colon (54,000 new cases), and cancer of the prostate (35,000 new cases) are among the most common diagnoses. Survival rates show that lip cancer and thyroid cancer have the highest survival rates (88 and 70% in all stages of disease, resp., for males), leukemia and cancer of the liver the lowest (5 and 2%, in all stages of disease, resp., for females.)

0280 CANCER MORTALITY IN RELATION TO NATIONAL CONSUMPTION OF CIGARETTES, SOLID FUEL, TEA, AND COFFEE. (E.) Stocks, P. (Colwyn Bay, Wales). *Brit J Cancer* 24(2):215-225, 1970.

Age-adjusted death rates from cancers of varying sites in 1964-1965 were compared to figures for annual consumption of cigarettes, solid fuel, tea, and coffee collected from trade statistics in 20 countries. One significant correlation found was that cigarette consumption per adult in the population is positively related with lung and bladder cancer in males and insignificantly with lung in females. Negative relations are indicated with the liver and biliary passages, prostate and uterus. Solid fuel is positively related with the intestine, lung and bladder in both sexes, with leukemia in males and with breast in females; however, negative associations are indicated with the stomach. Tea is positively related with intestine except rectum in both sexes and with larynx, lung and breast in females. Negative associations are indicated with the stomach in both sexes and with uterus and leukemia in females. Coffee is positively

related with the pancreas, prostate and leukemia in males and with ovary and leukemia in females. The contrasts observed between the intestine and stomach in their associations with solid fuel, cigarettes and tea may be explained by the susceptibility of a limited proportion of people at a given age to gastrointestinal cancer and an associated tendency of some carcinogens including those in cigarettes and coal to promote malignancy in the intestines; thus, more intestinal cancers and fewer gastric cancers are seen in countries where the environmental content of those carcinogens is high.

0281 CONTRACEPTIVES AND DYSPLASIA: HIGHER RATE FOR PILL CHOOSERS. (E.) Stern, E. (Sch. Publ. Hlth., U. California, Los Angeles), V. A. Clark and C. F. Coffelt. *Science* 169(3944):497-498, 1970.

Women enrolling in a family planning program were surveyed to determine if there was any relation between use of the oral contraceptive and incidence of cervical cancer. Of 166 women found to have cervical dysplasia prior to selection of a contraceptive method, 122 or 75% chose birth control pills, while 1354 out of 2220 women without dysplasia (61%) chose other methods. The women choosing the pill differed from those choosing IUD's in having a higher income and lower body wt, but no further differences were found over a wide range of demographic and biomedical characteristics, including religion, ethnic group, age, age at first intercourse, age at first pregnancy and number of children.

0282 CERVICAL CYTOLOGY AND MYCOPLASMA IN TWO POPULATIONS. (E.) Gregory, J. E. (Temple U. Sch. Med., Philadelphia, Pa.) and F. E. Payne. *Acta Cytol* 14(7):434-438, 1970.

The possibility of a correlation between mycoplasma infection and carcinoma was investigated in a study of cervical cytology in 2 groups of 150 women. One population was composed of patients visiting a venereal disease clinic; women attending a family planning clinic constituted the other group. The women were of similar socio-economic background, and ages ranged from 16 to 61 yr in the Venereal Disease (VD) group and from 15 to 45 in the Family Planning (FP) population. The prevalence of mycoplasma in the cervix of VD women was 92%, nearly 3 times as high as that in the FP subjects. *Mycoplasma hominis* Type 1 was the predominant species of mycoplasma that was recovered from both groups. Neither age nor the menstrual cycle significantly influenced the prevalence of mycoplasma in either population. In the FP women, observable cellular abnormalities occurred somewhat more often in women using oral hormones than in those using the intrauterine device or not employing any form of contraception. The proportion of abnormal smears was higher in the FP women than in the VD females, but mycoplasma did not significantly influence the occurrence of cellular abnormalities in either population. It is doubtful that a causal relationship exists between contraceptive technique and mycoplasma in the cervix.

0283 THE INCREASING INCIDENCE OF CENTRAL NERVOUS SYSTEM LEUKEMIA IN CHILDREN. (E.)

Evans, A. E. (Child. Hosp., Philadelphia, Pa.), E. S. Gilbert and R. Zanstra. *Cancer* 26(2):404-409, 1970.

Factors which may influence the incidence of CNS leukemia infiltration were investigated in a study of 209 children with acute leukemia, all of whom received the same chemotherapeutic agents. The incidence of symptomatic CNS leukemia was 51% (106/209), 97/173 of whom had lymphocytic or undifferentiated leukemia and 9/36 had other forms. The median survival was 21 months for patients with acute lymphocytic leukemia and 9 months for the other cell types. Life-table analysis showed a median survival of 8 months for patients who had developed CNS leukemia and 24 months for those free of the complication. Age, sex, hematologic status, and chemotherapy regimen did not influence the incidence. The increasing survival of children with leukemia appears to be the chief cause for the increased incidence of CNS leukemia.

0284 CANCER IN IRAN: A STATISTICAL STUDY. (Fr.)

Habibi, A. (Fac. Med. Teheran, Iran). *Bull Cancer* 57(1):133-150, 1970.

In order to obtain information on the prevalence of various forms of cancer in Iran, 28,069 identified cancer cases from the Teheran vicinity from all social classes and ages were studied. Malignant skin tumors were the commonest form of cancer (21.7%) and appeared to be related to exposure to the sun's rays, skin contact with dirty clothing, and to neglect of personal hygiene. Men were most frequently affected, with the male-female ratio approaching 2:1. Among women, cancer of the cervix was the most common, accounting for 21% of the female cases and, like skin cancer, occurred most frequently in patients of the lower social classes. Cancer of the lymphatic glands was widespread (8.1% of all cancer cases); it predominated in men, but occurs in all age groups. Breast cancer occurred in 6.2% of total cases and was most common among women of higher economic status. Cancer of the esophagus occupied fifth place in the general statistics, constituting 4.2% of the cases. Respiratory tract cancer accounted for 6.1% of total cases, with malignant tumors of the larynx and of the bronchii and lung contributing 3.3% and 2.8% of the total cases, resp.

0285 SALIVARY GLAND TUMORS IN EASTERN GERMANY FROM 1955 THROUGH 1958. (Ger.)

Otto, H. D. (Ear-Nose-Throat Clin., Humboldt U., Berlin, Germany), F. Bockmuhl and H. J. Herold. *Deutsch Gesundh* 25(29):1364-1368, 1970.

Six hundred and eighty-two patients with salivary gland tumors (604 parotid gland tumors and 78 submandibular tumors) were recorded in Eastern Germany between 1955 and 1958. Histological examination revealed 320 malignant tumors of which 265 were located in the parotid gland (120 male and 145 female patients), while 55 were located in the submandibular region (32 males, 23 females). Of 362 polymorphic ade-

nomas, 339 were located in the parotid (120 male and 219 female patients) and 23 were submandibular tumors (5 male and 18 female patients). Malignancy occurred mainly between the age of 60 and 80 and was rare before the age of 40, while polymorphic adenomas occurred at any age. Metastases appeared in 66 (22.6%) of the patients with malignant tumors and were more frequent in submandibular tumors (29%) than in parotid tumors (18.7%). Detailed histological differentiation, diagnosis, clinical symptoms and treatment, as well as literature data are given.

0286 THE EPIDEMIOLOGY OF LUNG CANCER: RECENT TRENDS. (E.)

Wynder, E. L. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), K. Mabuchi and E. J. Beattie, Jr. *JAMA* 213(13):2221-2228, 1970.

To test the hypothesis that tar is the principal lung cancer inducing factor in cigarette smoking, 340 patients with histologically proven lung cancer of Kreyberg group 1 or group 2 type were interviewed about their smoking habits. The investigation confirmed the close association between cigarette smoking and lung cancer, especially of the squamous and oat cell types. In addition, there was a decreased relative risk for those patients developing lung cancer 10 yr after switching to filter cigarettes, possible due to the lower tar content in filter cigarettes. The risk also declines after complete cessation of cigarette smoking, and appears to approach the risk level incurred by non-smokers after 13 years of abstinence from cigarettes.

0287 CARCINOMA OF THE BREAST IN WOMEN LESS THAN THIRTY YEARS OLD. (E.)

Norris, H. J. (Armed Forces Inst. Path., Washington, D. C.) and H. B. Taylor. *Cancer* 26(4):953-959, 1970.

Survival data on carcinoma of the breast for 135 women less than 30-yr-old were evaluated, and clinical and histologic features of the tumors in this series were examined to determine which features were associated with a particular clinical course; mammary cancer in women under 30 appeared to have a poorer prognosis than in older women. The poor prognosis may be explained by the finding that about 10% of the patients were pregnant or lactating—conditions associated with a higher incidence of axillary lymph node metastasis and lethal outcome. Furthermore, incidence of axillary metastasis was slightly higher in younger women, regardless of pregnancy, and carcinoma frequently (17%) developed in the opposite breast. Finally, patients with 1 or 2 positive axillary lymph nodes did poorer than expected. Despite the overall unfavorable outlook, crude survival was improved by the relative infrequency of deaths from causes other than cancer, as contrasted with that of older women. Also, the prognosis for women under 30 was improved by the relatively high proportion (24%) of low-grade infrequently metastasizing tumors, such as medullary intraductal, juvenile, papillary, and well-differentiated carcinomas. When only infiltrating duct carcinoma was considered, 5-yr survival in young women was 50% at 5 yr and 37% at 10 yr. The 5-yr survival rate for patients without axillary metastasis was 81% and the 10-yr figure was 74%, indicating that patients without axillary metastasis did as well as older women with breast cancer.

0288 HEXOKINASE, DIFFERENTIATION AND GROWTH
 RATES OF TRANSPLANTED RAT TUMORS. (E.)
Know, W. E. (Harvard Med. Sch., Boston, Mass.), S. C.
Jamdar and P. A. Davis. *Cancer Res* 30(8):2240-2244,
1970.

Hexokinase activity was measured in fetal, adult, and regenerating livers of rats, and in 18 different types of transplanted hepatic and nonhepatic rat tumors; findings were compared with measured growth rates in the same tissues and tumors to determine whether there was a correlation between hexokinase activity and growth rate. Concentrations of hexokinase in the transplanted tumors were significantly correlated with measured growth rates, and paralleled the progressive loss of histological differentiation of these tumors. The correlations found confirm the similar relationship already found among hepatomas and extends it to some nonhepatic tumors of the rat. The normal tissues, fetal and regenerating liver, grew equally as fast as the fastest tumors but contained significantly less hexokinase. Glutaminase concentration was also correlated with growth rate, although less strongly than hexokinase concentration.

0289 POPULATION KINETICS OF NORMAL, TRANSFORMING AND NEOPLASTIC CELL LINES. (E.)
Norby, K. (Dept. Path., U. Goteborg, Sweden). *Acta Path Microbiol Scand* 78(suppl. 214):1-29, 1970.

Population kinetics of normal, SV40-transformed, and neoplastic cell lines were studied quantitatively *in vitro* by cinemicrographically determining the effective birth, death, and growth rates during exponential growth, and the cell death probability was determined using both the exponential birth-death equation and a mathematical model of Jagers. Observations relating to various properties of normal and SV40-transformed cells revealed that the inoculum size was inversely proportional to the exponential growth rate, that transformed and neoplastic lines had higher cell densities than corresponding normal lines, that normal lines exhibited a much longer lag phase before mitosis resumed than the transformed species, and that mitotic activity during the observation period was greater for transformed cells than for normal cells. Biochemical analysis indicated unbalanced growth with regard to cytochrome oxidase (decrease with time) and ³H-leucine incorporation (increase with time), but balanced growth with regard to lactic dehydrogenase. In fetal human lines, the SV40-transformed lines showed higher mean mitotic times (27.20-34.05 min) than normal lines (24.34-28.47 min); the normal juvenile line BP211-2 had a longer mean mitotic time (37.75 min) than the normal fetal lines but shorter than the juvenile neoplastic line (39.00 min). The mean mitotic times for the Syrian hamster neoplastic lines were considerably longer (28.81-32.29 min) than the normal hamster lines (18.24-18.65 min). The normal cell lines exhibited a high death rate compared with the birth rates, while the SV40-transformed lines, the human neoplastic line and the hamster neoplastic lines had low death rates. Transformed cells and the neoplastic lines often have a lower birth rate than the normal lines, but a higher growth rate and a low death probability

(3.5-18.2% for normal fetal lines and 0 to 0.2% for transformed lines). Reduced cell death and prolonged average life span are characteristic neoplastic changes *in vitro*.

0290 PATTERNS OF GRANULOCYTE KINETICS IN ACUTE MYELOGENOUS AND MYELOMONOCYTIC LEUKEMIA. (E.) Galbraith, P. R. (Dept. Med., Queen's U. Kingston, Ontario, Canada), G. Chikkappa and H. T. Abu-Zahra. *Blood* 36(3):371-384, 1970.

Granulocytes from peripheral blood samples from 25 patients with acute myelogenous leukemia or acute myelomonocytic leukemia were subjected to kinetic studies using radioactive diisopropylfluorophosphate to investigate the more differentiated cells present. Leukocytes were labeled *in vitro* and then returned into the circulatory system. The patterns of disappearance of *in vitro* labeled leukocytes from the blood, and the patterns of emergence of *in vivo* labeled leukocytes from the bone marrow were variable. Nonuniformity in the results suggests that the terms acute myelogenous leukemia and acute myelomonocytic leukemia cover a spectrum of disorders, and that broad generalizations concerning their kinetics cannot be made. The variation in the data suggests that the mature neutrophils in the blood of leukemic patients may arise from abnormal or leukemic precursors.

0291 THE GROWTH CHARACTERISTICS OF AN ASCITIC PLASMACYTOMA (MP 5563) TERMINATING BY FISTULOUS COMMUNICATION WITH THE BLOOD STREAM. (E.) Fakhri, O. (Roy. Postgrad. Med. Sch., London, England). *Brit J Cancer* 24(2):389-394, 1970.

Cells from an ascitic plasmacytoma were injected i.p. into mice (0.2 ml of fluid containing 5 million tumor cells/ml), and the growth of the plasmacytoma was monitored by ⁵¹Cr-RBC dilutions within the peritoneal cavity together with differential cell counts and protein measurements. Following the i.p. transplantation, there was a latency period of 4 days, possibly explained as only a 5% survival of the inoculum. This was followed by logarithmic growth from 4 to 8 days with a doubling time of 18 hr, always similar in different animals. Eventually, after 8 days and after about 100 million cells, an asymptote was reached which was apparently due to a fistula-like communication between blood-stream and peritoneal cavity. This terminal phase (9-10 days) was rapidly followed by death of the mouse.

0292 NATURAL CAUSES OF VARIATIONS IN THE WEIGHT OF SARCOMA 180. (E.) Austin, J. P. (Unilever Res., Welwyn Garden City, Hertfordshire, England) and E. M. Glaser. *Brit J Cancer* 24(2):398-406, 1970.

Male and female mice of differing strains were implanted in the axillary regions with sarcoma 180 tumors and then maintained in environments varying in temperature, in order to test the effects of temperature, sex and strain on the weights attained by the implanted sarcomas. In 2 strains of mice (Swiss and hybrid) in which both sexes were studied the

tumor weights were lower in females; in 3 varieties the tumors weighed less at lower environmental temperatures than at higher ones. At 3 environmental temperatures in the physiological range (7, 24, and 35.5°C) the surfaces were cooler than the adjacent skin, and the tissues of tumors were cooler than the surrounding subcutaneous tissues. These differences were greater in cooler than in warmer environments and increased as tumors grew larger. There were no histological changes to account for the different tumor weights at different environmental temperatures, and it seems probable that tumors are unable to maintain their temperature and their metabolism in cool environments. Mice of the same breed maintained at room temperature showed a pattern of tumor development in which the largest tumors developed in the smallest mice.

- 0293 BEHAVIOR OF MINIMUM-DEVIATION HEPATOMAS IMPLANTED INTO CHICK EMBRYO BLASTODERMS. (E.) Sherbet, G. V. (Inst. Cancer Res., London, England). M. S. Lakshmi and H. P. Morris. *J Nat Cancer Inst* 45(3):419-428, 1970.

Six Morris hepatomas differing in growth rate and karyotype deviation were implanted into 16-18 hr chick embryo blastoderms, and their behavior and specificity of interaction with the embryo cells were assessed. Grafts placed between the embryonic germ layers showed considerable mobility ("takes") and the frequency of "takes" was related to their growth rate. Normal heterografts were invariably covered on all sides by large masses of host mesoderm, except on the side opposed to the endodermal layer of the embryo; the response elicited by Morris hepatomas did not differ significantly from that of normal liver. The hepatomas also induced a characteristic proliferation of the embryonic endodermal cells, but 4 types of tumor cells of mesodermal origin did not have this ability. The extent of both host mesodermal and embryonic endodermal responses appeared to depend on the degree of karyotype deviation. The responses were diametrically opposite but complementary and constant, whether the grafts were derived from hepatomas or from normal liver. These parameters of behavior may be used to assess the degree of tumor progression, differentiation and to detect early neoplastic changes or tendencies in normal tissues.

0304 ENVIRONMENTAL INFLUENCE ON EXPERIMENTAL TERATOCARCINOGENESIS IN TESTES OF MICE.

(E.) Stevens, L. C. (Jackson Lab., Bar Harbor, Me.). *J Exp Zool* 174(4):407-414, 1970.

The importance of hormone concentration and temperature in experimental teratocarcinogenesis was determined by following the grafts of male genital ridges from 12- or 13-day fetuses to various sites in adult mice of strains 129, A/He, and their F₁ hybrids. In grafts to scrotal sites (epididymis, epididymal fat pad, and testis) in the 129 strain, the incidence of teratomas was 61%, 44%, and 82%, resp., compared to the spontaneous incidence of 10%. In the A/He strain 12-day grafts resulted in 60%, 47%, and 43% incidence rates, resp., while in the hybrids the incidence was 61%, 51%, and 90%. Grafting of genital ridges to extra-scrotal sites (spleen, liver, kidney, renal fat pad, and ovarian fat pad) resulted in an overall incidence of 8% in the 129 strain and no teratomas in the A/He strain indicating that these sites do not favor teratocarcinogenesis; however, an overall occurrence of 3% in the hybrid strain was much higher than the spontaneous incidence, indicating that some factor involved in these grafts was teratocarcinogenic. Grafting to unilaterally cryptorchid hosts demonstrated the role of the lower temperature in the descended testes with 5% incidence in strain 129 with descended testes compared to 45% in cryptorchid testes, and 42% and 4%, resp., in the A/He strain. The incidence of teratomas was not significantly different in hosts receiving testosterone (70 µg daily beginning 2 weeks before grafting) from that in non-injected hosts (7% and 3%, resp.) so that sex hormones are not implicated in the experimental production of teratomas.

0305 THE RATIO OF ALBUMIN SYNTHESIS TO TOTAL PROTEIN SYNTHESIS IN NORMAL RAT LIVER, IN HOST LIVER, AND IN MORRIS HEPATOMA 9121. (E.)

Rotermund, H. M. (Biochem. Inst. U. Freiburg, Germany), G. Schreiber, H. Maeno, U. Weinssen and K. Weigand. *Cancer Res* 30(8):2139-2146, 1970.

The ratio of albumin synthesis to total protein synthesis was studied in livers from normal rats and rats bearing Morris hepatoma 9121 injected with radioactive leucine 12 min prior to sacrifice. Within this time, no newly synthesized radioactive protein had left the liver, since labeled protein appeared in the blood no earlier than 15 min after injection. Albumin was purified from livers and hepatomas to constant specific radioactivity. The specific radioactivity of albumin purified from normal liver was 100 times higher than that of albumin from tumor. In normal liver, the radioactivity incorporated into albumin was 3.7% of that found in total protein, and in host liver, 2.8% of total protein radioactivity was found in albumin; in hepatoma only 0.36% of labeled leucine incorporated into protein was measured in albumin. Albumin synthesis appears to be greatly decreased in Morris hepatoma 9121 compared to normal liver.

0306 STUDIES ON THE MECHANISMS OF INVASION IN CANCER: I. ISOLATION AND PURIFICATION OF A FACTOR CHEMOTACTIC FOR CANCER CELLS. (E.)

Yoshida, K. (Kumamoto U. Med. Sch., Japan), T. Ozaki, K. Ushijima and H. Hayashi. *Int J Cancer* 6(1):123-132, 1970.

The pseudoglobulin fraction of certain animal and human tumor tissues (gastric cancer, hepatoma, and a renal metastasis of myeloid leukemia) yielded a protein substance (molecular wt approximately 70,000) chemotactic for cancer cells. It was highly purified by column chromatography using Sephadex G-50 and CM-Sephadex and then by disc electrophoresis; it behaved as a homogenous substance on disc electrophoresis. The substance was thermolabile and had no proteolytic activity. The material was similarly active for rat ascites hepatoma AH109A cells, mouse ascites hepatoma MH134 cells and mouse myeloid leukemia C-1498 cells, suggesting a common chemotactic action. It was ineffective for polymorphonuclear leukocytes of rats. The protein fraction from normal skin and muscle showed no such chemotactic efficacy.

0307 COMPARISON OF ERYTHROPOIETIN RESPONSE IN MICE FOLLOWING POLYCYTHEMIA INDUCED BY TRANSFUSION OR HYPOXIA. (E.)

OKunewick, J. P. (Allegheny Gen. Hosp., Pittsburgh, Pa.) and D. Fulton. *Blood* 36(2):239-245, 1970.

Male mice were given s.c. injections of erythropoietin (6 U/25g body wt) to assess the response to erythropoietin during the first 2 wk after the induction of polycythemia by hypoxia or by transfusion. A 50% higher level of iron incorporation was observed with hypoxia-induced polycythemia compared to transfusion-induced polycythemia. An alteration in both the compartment size and the cell cycle time of the erythropoietic stem cell in mice exposed to prolonged hypoxia may account for this difference.

0308 A STUDY OF ENVIRONMENTAL INFLUENCE UPON SALIVARY GLAND NEOPLASIA IN RATS. (E.)

Rowe, N. H. (Sch. Med., U. Michigan, Ann Arbor), F. C. Grammer, F. R. Watson and N. H. Nickerson. *Cancer* 26(2):436-444, 1970.

Weanling rats (230) were randomized into 7 groups and subjected to conditions of vitamin A deficiency, hypercortisonism, hyperthyroidism, a combination of the last 2, and a windy, cold and humid environment to test the effects of these conditions on submaxillary salivary glands challenged with implanted 7,12-dimethylbenzanthracene; the aim was to develop an animal model for the relationships between nutritional, endocrine and thermal carcinogenic co-factors and the high incidence of salivary gland cancer in Arctic Eskimos. Animals were sacrificed at 14 weeks. Of the 7 regimens, only vitamin A deficiency increased malignant epithelial neoplasm yield (56% compared to 19% in control animals). The other 6 groups showed no significant differences.

0309 CYTOPLASMIC RIBONUCLEIC ACID SYNTHESIS IN THE PREREPLICATIVE PHASE OF ISOPROTERENOL-INDUCED CELL PROLIFERATION. (E.)

Baserga, R. (Temple U. Sch. Med., Philadelphia, Pa.) and T. Sasaki. *Exp Molec Path* 13(1):25-35, 1970.

MISCELLANEOUS

The appearance of radioactivity in the cytoplasmic RNA of pooled salivary gland homogenates prepared from mice injected with ^3H -uridine following i.p. administration of isoproterenol (0.8 $\mu\text{moles/g}$ body wt), a compound known to induce DNA synthesis and cell proliferation, was studied. The minimum time required for the appearance of radioactivity in cytoplasmic ribosomal RNA was the same in unstimulated and stimulated glands; however, the incorporation of ^3H -uridine into cytoplasmic rRNA was much higher in stimulated than in control glands, at 8, 18 and 20 hr after isoproterenol administration. The increase in incorporation of ^3H -uridine was essentially the same in free and membrane-bound ribosomes, and this increase was completely inhibited by inhibitors of isoproterenol-stimulated DNA synthesis such as actinomycin D and cycloheximide. The incorporation of ^3H -uridine into polydisperse (6 S-16 S) cytoplasmic RNA increased sharply at 8 hr after isoproterenol. Evidently, gene activation becomes notable only several hr after administration of isoproterenol in mouse salivary glands.

- 0310 ISOLATION OF MYCOPLASMA FROM LEUKEMIC AND NONLEUKEMIC PATIENTS. (E.) Murphy, W. H. (U. Michigan Med. Sch., Ann Arbor), C. Bullis, L. Dabich, R. Heyn and C. J. D. Zarafonitis. *J Nat Cancer Inst* 45(2):243-251, 1970.

Various methods for isolating *Mycoplasma* spp (mycoplasma) from clinical specimens obtained from leukemic and nonleukemic patients were examined for a relative effectiveness. From 1,950 specimens, 71 strains of mycoplasma were isolated, twenty-seven of which were isolated directly on artificial media. Various basal media, with and without additives, were tested for their capacity to grow mycoplasma from clinical specimens. None of the commonly used media containing fresh yeast extract were clearly superior or inferior to others. Cell culture methods were about 4-fold more effective than direct bacteriologic methods. The combined use of fresh specimens, direct bacteriologic, and cell culture methods for isolating mycoplasma gave an overall frequency of recovery of about 3%. In general, bone marrow specimens were positive less frequently than peripheral blood specimens. Mycoplasma were isolated more frequently from children than from adults, and specimens from leukemic children at diagnosis, or when disease was in relapse, were positive most frequently; specimens from children with nonlymphoid malignancies or blood dyscrasias, also were positive frequently. The evidence from this study suggests that mycoplasma, normally inhabiting the mucous membranes, enter the bloodstream and either persist or multiply in patients with leukemia, lymphoma, or other diseases which depress immunity, but are not significant as a prime etiologic agent.

- 0311 FOCAL AVILLOUS HYPERPLASIA OF THE MOUSE DUODENUM. (E.) Seronde, J., Jr. (Harriet G. Bird Mem. Lab., Stow, Mass.). *J Path* 100(4):254-248, 1970.

A synthetic diet deficient in pantothenic acid was given to mice in order to produce hyperplastic avillous mucosa in their proximal duodenum, which were

examined by light microscopy. The lesions were flat plaques composed of large numbers of parallel tubules derived from the crypts of Lieberkühn. The glandular epithelium was anaplastic at deeper levels, and 2 or more tubules tended to combine to form common passage near the surface. The lesions were small and rare in mice fed on a stock diet, conspicuous in mice fed on a complete synthetic diet, and more severe when pantothenic acid was omitted from the synthetic diet. The lesions probably arise through continuing multiplication of crypt epithelial cells, combined with a failure of their differentiation into mature villus cells. Acute superficial necrosis and ulceration occurring on areas of avillous hyperplasia, and sometimes followed by characteristic deep chronic ulceration were encountered in pantothenic acid-deficient mice.

- 0312 EFFECTS OF ERGOCORNINE AND 2-Br- α -ERGOKRYPTIN (CB-154) ON THE FORMATION OF MAMMARY HYPERPLASTIC ALVEOLAR NODULES AND THE PITUITARY PROLACTIN LEVELS IN MICE. (E.) Yanai, R. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan) and H. Nagasawa. *Experientia* 26(6):649-650, 1970.

The effects of ergocornine and 2-Br- α -ergokryptin on the formation of mammary hyperplastic alveolar nodules and on the pituitary prolactin levels were determined in 7-8-months-old multiparous C3H/He female mice more than 1 month after the last lactation. Mice were treated with s.c. injections of 0.2 mg ergocornine methanesulfonate or 2-Br- α -ergokryptin daily for 20-23 days and sacrificed when they showed proestrous to estrous smears. The number of hyperplastic alveolar nodules and the degree of lobulo-alveoli formation were decreased 54% and 40% resp., in treated mice compared to controls. The anterior pituitary weight decreased about 20% and the prolactin content fell approximately 45% in treated mice compared to controls. Ergocornine and 2-Br- α -ergokryptin appear to lower pituitary prolactin contents and concentrations, and secondarily inhibit development and growth of hyperplastic alveolar nodules.

- 0313 CYTOPATHOLOGY OF CERVICAL SQUAMOUS CARCINOMA *IN SITU* IN POSTMENOPAUSAL WOMEN. (E.) Tweeddale, D. N. (U. Kentucky Coll. Med., Lexington) *Acta Cytol* 14(7):363-369, 1970.

Two groups of women with cervical squamous carcinoma *in situ*, 1 consisting of women between 24-49 yr old (the premenopausal group), and 1 consisting of women between 50-81 yr old (the postmenopausal group) were studied to investigate the differential cytologic features in the 2 groups. The most important differentiating cytologic features between postmenopausal and premenopausal women is that the former have a greater number of malignant cells with keratinizing tendencies and a lesser number that are parabasal. Also, postmenopausal women commonly have an unusual background resembling necrosis seen with invasive cancer. Postmenopausal women having only *in situ* cancer may be incorrectly diagnosed as cases of invasive malignancy due to a combination of these cytologic findings.

14 ETIOLOGY OF BONE CANCER AND SOME OTHER CANCERS IN THE YOUNG. (E.) Hems, G. (U. d. Buildings, Aberdeen, Scotland). *Brit J Cancer* (2):208-214, 1970.

comparison of growth velocities during adolescence with histograms for bone cancer mortality in England and Wales showed that changes in bone tumor development followed closely the growth changes at adolescence, with a lag of less than 2 or 3 yr between growth peaks and modal ages for bone cancer mortality. Distinct accumulations in the second and third decades of life could also be recognized for cancer of the ovary, testis, prostate and thyroid, suggesting that these accumulations might be associated with rapid growth and development occurring at puberty. The exposure of bone, ovary, testis and prostate to carcinogens might result in a higher incidence of cancer if that exposure occurred before puberty.

15 POLYAMINE SYNTHESIS IN RAPIDLY GROWING TISSUES. (E) Snyder, S. H. (Johns Hopkins Sch. Med., Baltimore, Md.) and D. H. Russell. *J Proc* 29(4):1575-1582, 1970.

Polyamines (associated with rapid tissue growth) are formed by a combination of ornithine and S-adenosylmethionine which have been decarboxylated, possibly by the same enzyme, and the activity of ornithine decarboxylase were determined in regenerating rat liver, in developing chick embryo, and in certain tumors by estimating $^{14}\text{CO}_2$ evolved after incubation with ornithine- $1\text{-}^{14}\text{C}$. As early as 1 hr after partial hepatectomy ornithine decarboxylase activity increased 3-fold (30 mμC/30min/g) in the rat liver; 1 hr after partial hepatectomy the activity had risen to 25 times the control values. In the chick embryo ornithine decarboxylase reached a peak activity (530) at 5 days then gradually declined to no detectable activity at 20 days. Analysis of histidine and ornithine decarboxylase activities in tumors revealed an inverse relation between them. A hepatoma, STAT-3 sarcoma, and NRF-TFF carcinoma had high histidine decarboxylase (35.6, 10, and 22.2, resp.) and low ornithine decarboxylase (11.6, 2.7, and 3.1, resp.) activities, while STAT-1 sarcoma had a high ornithine decarboxylase (11.2) and a low histidine decarboxylase (2.5) activity.

16 NASOPHARYNGEAL CARCINOMA IN CAUCASIAN SIBLINGS: REPORT OF TWO CASES. (E.) R. B. (U. Tennessee Coll. Med., Memphis) and A. Maguda. *J Tennessee Med Ass* 63(9):753-754, 1970.

Case of sibling occurrence of nasopharyngeal carcinoma in Caucasians (a relatively unusual tumor in Caucasians) is described. Geographical contiguity with another reported case of nasopharyngeal carcinoma was noted, but it was not assumed that the contiguity was attributable to more than chance. In neither sibling described was there any history of exposure to chemicals or industrial toxins; neither sibling used alcohol regularly, al-

though one of them commonly smoked one and a half packs of cigarettes daily.

0317 EXTRAUTERINE GROWTH OF MOUSE EGG-CYLINDERS RESULTS IN MALIGNANT TERATOMA. (E.) Solter, D. (Fac. Med. Zagreb, Yugoslavia), N. Skreb and I. Damjanov. *Nature* 227(5257):503-504, 1970.

The effect of mouse egg-cylinders transplanted to extrauterine sites was investigated. Egg cylinders isolated from pregnant uteri of C3H/H mice were transplanted under the kidney capsule of each of 21 3-month-old male mice of the same strain. At sacrifice, an average of 6 months after transplantation, 11 animals had teratomas weighing 0.5-3.5 g, and 10 animals had tumors weighing 7-15 g at 4 months after transplantation. All tumors were sharply demarcated from the kidney parenchyma, and no metastases were found. Histological examination showed that the small tumors were composed predominantly of mature differentiated tissues originating from all three germ layers; in addition, the large tumors were comprised of up to 50% undifferentiated epithelial or mesenchymal tumors.

0318 CHRONIC LYMPHOCYTIC LEUKEMIA AND SUBSEQUENT CANCER IN THE SAME PATIENT. (E.)

Stavraky, K. M. (Dept. Commun. Med., U. Western Ontario, London, Canada), T. A. Watson, D. F. White and E. M. Miles. *Cancer* 26(2):410-414, 1970.

The occurrence of second cancers diagnosed after the onset of chronic lymphocytic leukemia was examined in 258 patients to see if a relationship existed between the leukemia and second cancers. In 825 person-years of observation, 13 second cancers appeared after diagnosis of chronic lymphocytic leukemia, but this occurrence was no greater than that expected in the normal population. No relationship appears to exist between chronic lymphocytic leukemia and other cancers.

0319 THE EFFECT OF HYPERMETHYLATION ON THE FUNCTIONAL PROPERTIES OF TRANSFER RIBONUCLEIC ACID: RIBOSOME-BINDING AND POLYPEPTIDE SYNTHESIS. (E.) Hay, J. (Coll. Physicians Surgeons, Columbia U., New York, N. Y.), D. J. Pillinger and E. Borek. *Biochem J* 119(3):587-593, 1970.

Since tRNA of tumor tissue has an abnormal methylated base content, the action of hypermethylated (dimethylsulfate method of Pillinger, Hay and Borek) tRNA (*Escherichia coli* tRNA) in an *in vitro* ribosome-binding assay and a polypeptide-synthesizing system was studied. The hypermethylated tRNA proved stable under the ribosome-binding assay conditions and was able to bind to ribosomes with the same efficiency as normal tRNA after the proportion of amino acid residues present was adjusted. The relative ability of the hypermethylated tRNA to form polyphenylalanine *in vitro* was inversely proportional to the amount of methylation with an absolute value of 80% inhibition. Polylysine synthesis was 60% inhibited while poly-L-proline was 100% inhibited by 7 mole% hypermethylated tRNA. Aminoacylation (for-

MISCELLANEOUS

mation of the aminoacyl-tRNA) was less affected by hypermethylation, with polylysine synthesis again less sensitive (22% inhibition) than polyphenylalanine (50%) and polyproline (50%) syntheses.

- 0320 MURAMIDASE IN POLYCYTHEMIA VERA. (E.) Binder, R. A. (Mount Sinai Hosp., New York, N. Y.) and H. S. Gilbert. *Blood* 36(2):228-232, 1970.

Serological studies were performed on 45 patients with polycythemia vera in order to confirm the presence of increased muramidase in this condition and to study the relationship of the muramidase level to other features of polycythemia vera. The serum muramidase levels of the polycythemia vera patients were significantly elevated above the values in 20 normal subjects (12-16 $\mu\text{g/ml}$ vs. 9 $\mu\text{g/ml}$). The patients with polycythemia vera who were studied included those with active disease, those controlled with myelosuppressive agents and those in the spent phase. A high degree of correlation was found between muramidase levels and leukocyte count, granulocyte count, serum uric acid, serum vitamin B₁₂ content and unsaturated vitamin B₁₂ binding capacity. No correlation was found between muramidase levels and hematocrit, monocyte count and leukocyte alkaline phosphatase activity. The results appear to support the thesis that serum muramidase originates from granulocytes, and the involvement of the granulocyte in the proliferative process responsible for polycythemia vera may be reflected in the elevated levels of serum muramidase in patients with this condition.

- 0321 CARCINOMA OF THE BREAST: ST. VINCENT'S HOSPITAL SERIES, 1954-1965: THE EFFECTS OF CHILDBEARING ON CARCINOMA OF THE BREAST. (E.) Fleming, J. (St. Vincent's Hosp., Sydney, Australia), B. Sheridan, L. Atkinson and G. Scott, *Med J Aust* 57(25):1252-1256, 1970.

A series of 1,840 patients with breast cancer was studied to determine the effect of previous pregnancy and lactation on the disease, the effect of pregnancy and lactation coincident with the onset of the disease and the effect of pregnancy commencing after treatment of carcinoma of the breast. Approximately 24% of cases of breast cancer occurred in women who had "never lactated," (where the comparison group consisted of women who had produced live children whom they might or might not have fed.) Lactation did not appear to influence the stage of the disease with which the patient first presented; however, it did affect the 5 yr survival rates for patients in differing stages of breast cancer, the rate being 70% for those in the second stage of the disease who had not lactated and 57% for those who had. The survival rate for patients who had had a child was 50%, and 60% for those who had had no children. The incidence of breast cancer commencing in pregnancy was 0.6%; the mean age of these patients was 37 yr, and most had had previous pregnancies. The average age of patients who became pregnant after previous treatment for breast cancer was 35.5 yr, and all but 1 had had previous pregnancies.

- 0322 INITIAL STAGE OF HEMATOGENOUS METASTASIS OF ⁵¹Cr-LABELED TUMOR CELLS. (E.) Suemasu, K. (Nat'l. Cancer Ctr. Hosp., Tokyo, Japan), M. Katagiri, Y. Shimozato, M. Mikuni, and S. Ishikawa. *Gann* 61(1):7-15, 1970.

The relationship between initial organ distribution of hematogenously disseminated tumor cells and subsequent patterns of organ metastasis was investigated in male rats were given i.p. injections of ⁵¹Cr-labeled cells of a transplantable lung carcinoma and Yoshida ascites sarcoma. The relationship between the distribution pattern of ⁵¹Cr-labeled tumor cells immediately after intracardiac injection and patterns of organ metastasis 6-14 days after inoculation of non-labeled tumor cells was examined. The distribution of labeled cells/g of organ at 5 min after injection was 14.7, 5.1, 1.4 and 1.4% for lungs, kidneys, brain and adrenals, resp., with the lung carcinoma cells; the distribution of label was 17.5, 2.9, 1.8, 1.2 and 0.8% for lungs, kidneys, liver, spleen and adrenals, resp., with the Yoshida ascites sarcoma cells. Organs which accumulated less label in the initial period than those mentioned above tended to have rare incidences of metastasis. Measurement of the cells by radioactivity indicated that the stay of the cells in the organs was transient and that the ability of tumor cells to pass through organs differed according to the strain of tumor. Such a difference may also influence the organ selectivity of hematogenous metastasis. As time elapsed, tumor cells in the circulation lost their viability, and cellular debris accumulated in the liver and spleen. The half-life of tumor cells which did not metastasize to any organ was evidently not long.

- 0323 POSTMORTEM OBSERVATIONS ON FISCHER RATS WITH LEUKEMIA AND OTHER DISORDERS. (E.) Davey, F. R. (Child. Cancer Res. Found., Boston, Mass.) and W. C. Moloney. *Lab Invest* 23(3):327-334, 1970.

Because of the high incidence of spontaneous leukemia reported among inbred Fischer rats, the pathological features of this and other disorders were followed until natural death or sacrifice at a terminal stage in 43 male and 43 female animals. The average age at death was 23.9 months (range 11-32 months), and a severe pulmonary infection was detected in all the animals at postmortem; 65.1% of the males had interstitial cell tumors of the testis, and 10.4% of the rats had various subcutaneous tumors. Of the 86 rats, 24.4% had leukemia marked by enlarged spleens (average weight of 9.0 g compared to the control nonleukemic value of 0.9 g) and mottled livers. Infiltration of the spleen, liver, lymph nodes, and lungs was observed in all cases, while the kidney, heart, and gastrointestinal tract were less frequently involved. The bone marrow showed evidence of infiltration in only 3 cases.

- 0324 EPIZOOTIC RETICULUM CELL SARCOMA IN A SEQUESTERED COLONY OF JAPANESE QUAILS. (E.) Nishimura, E. T. (U. Hawaii Sch. Med., Honolulu), E. Ross, G. Leslie, H. Y. Yang and Y. Hokama. *Cancer Res* 30(8):2119-2126, 1970.

the epizootic nature and the pathological features of a spontaneous avian leukosis (reticulum cell sarcoma) observed in a sequestered colony of Auburn strain 571 Japanese quails are presented. The incidence of the spontaneous tumor development was 1.8% (30 out of 47 quail), and the tumors appeared when the quail were between 8 and 22 months of age. Gross pathological examination revealed varied degrees of thymic prominence, enlarged spleens, and frequent tumor infiltration of the bursa of Fabricius, liver, duodenum, caeca, and bone marrow. Electron micrographs demonstrated intranuclear spherical bodies (1200 Å diameter) that had hollow centers surrounded by a concentric and fibrillar double wall and contained a small (200 Å diameter), centrally-positioned electron-dense dot. Although these spherical bodies were not encountered in the liver of a few healthy quails, the significance of the particles remains speculative.

25 CHROMOSOME ABNORMALITIES IN POLYPS AND CARCINOMAS OF THE LARGE BOWEL. (E.) Baker, C. (Mount Vernon Hosp., Northwood, Middlesex, England) and N. B. Atkin. *Proc Roy Soc Med* 63 (suppl.):9-10, 1970.

Chromosome abnormalities in polyps of the large bowel which may have malignant potential are described. In contrast to carcinomas, polyps present minimal changes such as the acquisition of 1 or 2 extra C group chromosomes. Carcinomas show a tendency towards the presence of few B, D and G group chromosomes, but this does not appear to be a feature of premalignant lesions. A malignant cell-line probably does not result from such minimal changes as is seen in polyps, but can result if random secondary chromosome changes also occur. (references)

26 JUVENILE POLYPS OF THE COLON AND THEIR RELATIONSHIP TO ALLERGY. (E.) Alexander, H. (Child. Orthop. Hosp., Med. Ctr., Seattle, Wash.), J. B. Beckwith, A. Morgan and A. H. Bill. *Br J Surg* 120(2):222-225, 1970.

The presence of eosinophils infiltrating juvenile polyps of the colon usually denotes an allergic reaction. The possibility that the polyps are a result of allergy was accordingly studied. Questionnaire responses in 13 cases of juvenile polyps and control cases of hernia showed the following: 11 of 13 patients with polyps (85%) had a personal or family history of allergy, whereas only 5 of 18 (28%) with hernia had a similar history; personal history of allergy was present in 46% of children with polyps, and in 17% of children with hernia; family history of allergy occurred in 77% of those with polyps, and in 17% of patients with hernia. These results are statistically significant, and support the hypothesis that allergy and juvenile polyps may be related. These findings characterize more thoroughly the setting in which such polyps may appear, and lend support to those investigators who believe that juvenile polyps have no malignant potential.

0327 CYTOCHEMICAL STUDIES OF SKELETON NEOPLASMS. (E.) Petrova, A. S. (Acad. Med. Sci. USSR, Moscow) and N. A. Probatova. *Folia Histochem Cytochem* 8(2):135-144, 1970.

Data from cytochemical studies of alkaline and acid phosphatases and the PAS reaction in cells of osteogenic sarcoma, osteoblastoclastoma, Ewing's sarcoma, and reticulosarcoma ossis were examined to investigate the enzyme activities in these tumors. An exceedingly high level of the alkaline phosphatase activity was revealed in the cells of osteogenic sarcoma, a moderate activity level, both of alkaline and of acid phosphatases in the cells of Ewing's tumor, and a weak activity of both the hydrolases investigated in the mononuclear cells of osteoblastoclastoma. The high activity of alkaline phosphatase in the cells of osteogenic sarcoma may be an expression of fibrillogenesis, a specific function of osteoblasts.

0328 BONE MARROW COLONIES: STIMULATION *IN VITRO* BY SUPERNATANT FROM INCUBATED HUMAN BLOOD CELLS. (E.) Chervenick, P. A. (U. Pittsburgh Sch. Med., Pa.) and D. R. Boggs. *Science* 169(3946):691-692, 1970.

Blood from healthy adults was incubated for 10-14 days at 37 C in 6.5% CO₂ to give a supernatant which stimulated the growth of granulocytic and mononuclear cell colonies from mouse and human bone marrow; such a stimulant may function to regulate granulocytic and mononuclear cell growth in normal individuals and in individuals with diseases of the hematopoietic system. The stimulant was resistant to heat and freezing, and could not be dialyzed. Supernatants from sonically disrupted cells and irradiated cells had no colony-stimulating activity by 7 days; the addition of sonically disrupted cells or irradiated cells or plasma to an active supernatant reduced its activity by 40%. Results suggest that the stimulating substance is not stored within the cells, but is produced and released during incubation.

0329 MUCOSUBSTANCES IN NORMAL AND IN NEOPLASTIC MAST CELLS OF THE DOG. (E.) Mariano, M. (Sch. Vetr. Med., U. San Paulo, Brazil). *Acta Histochem* 36(1):14-23, 1970.

Mastocytomas from 9 dogs were subjected to histochemical examination to detect mucosubstances present in neoplastic canine mast cells; both benign and malignant tumors were assayed and compared to normal cells. Although glycogen could not be demonstrated in either normal or neoplastic tissue, neutral, sulfated (heparin), and carboxylic (sialic acid) mucosubstances were found in both normal and neoplastic mast cells. Neoplastic cells also appeared to contain a hyaluronic-acid-like mucosubstance, which was characterized by its alcianophilia at pH 2.5, its metachromasia at pH 5.6 and not below, and by its testicular hyaluronidase and pyocyanine lability.

- 0330 MALIGNANT TUMORS AND CHROMOSOMAL ABERRATIONS. (E.) Schuler, D. (U. Med. Sch. Budapest, Hungary) and M. Dobos. *Acta Paediat Acad Sci Hung* 11(1):3-10, 1970.

Chromosome susceptibility to breakage induced by an alkylating agent, R-52, was studied in peripheral blood cell cultures of patients with malignant tumors, to investigate the correlation of chromosomal aberration with malignancy, and to determine if chromosomal aberrations in malignancy patients is a primary or a secondary phenomenon. The literature of chromosome aberrations in malignancies is reviewed, and the authors' own findings are presented. Chromosome breakages and translocation figures appeared in the cells of patients with Fanconi's anemia, a disease which may predispose to leukemia. Unusually high incidence of chromosome breakage was also found in patients with lymphoreticular tumors, Bloom's syndrome and agammaglobulinemia.

- 0331 ACTIVITIES OF DNA POLYMERASE IN HUMAN UROGENITAL TUMORS. (E.) Shimazaki, J. (Sch. Med., Gunma U., Japan), H. Takahashi, H. Nagai and K. Shida. *Gann* 61(1):47-53, 1970.

DNA polymerase activity was assayed in various human urogenital tumors to investigate the relationship between DNA synthesis and malignant growth. In all tissues examined, the enzyme showed 2- to 10-fold higher activity in the presence of heat-denatured DNA than native DNA as the template. In some tumors which exhibited elevated activity of DNA polymerase, there was a large difference between the activity with native DNA and heat-denatured DNA. In benign prostatic hypertrophy and prostatic carcinoma the level of DNA polymerase activity was relatively low; while in testicular tumors, pelvic kidney tumors, some bladder tumors, and Grawitz tumor DNA polymerase activity was high.

- 0332 BONE MARROW COLONY-STIMULATING FACTOR: RENAL INFLUENCE ON SERUM TITERS. (E.) Foster, R. S., Jr. (U. Vermont Coll. Med., Burlington). *J Surg Oncol* 2(1):1-8, 1970.

The factor in mouse bone marrow cells which stimulates the *in vitro* proliferation of bone marrow cells, resulting in the formation of colonies of granulocytic and mononuclear cells, was titrated in the serum of female mice which had undergone either unilateral or bilateral ureteral ligation, or unilateral or bilateral nephrectomy; the aim was to determine if renal mechanisms capable of influencing the response of the serum colony-stimulating factor exist. The serum titer of the colony-stimulating factor was elevated 18 hr following bilateral ureteral ligation and following either unilateral or bilateral nephrectomy. At 3 and 7 days following unilateral ureteral ligation, there was a moderate elevation of colony-stimulating activity. Renal clearance of the colony-stimulating factor influences the titer of the serum colony-stimulating factor.

- 0333 MULTIPLE MYELOMA WITHOUT PARAPROTEIN. (E.) Szucs, J. (U. Med. Sch. Budapest, Hungary). *Haematologia* 4(1):97-102, 1970.

DESCRIPTION OF INDEXES

The SUBJECT INDEX is based on a hierarchial system of classification in which *major index terms* are modified by one or more *key word descriptors*. The *key word descriptors* are listed in decreasing order of importance and describe the content of the abstract or citation. In addition, in this indexing system, some *key word descriptors* will also be used as *major index terms*, thus providing in-depth indexing of each document. An abstract or citation number, in brackets, will be found after the *key word descriptors*. Citations will be identified by an asterisk outside of the brackets.

An illustrative example of this indexing system follows:

LIVER

Hepatoma, N,N'-2,7-fluorenylenebisacetamide, X-irradiation

N,N'-2,7-FLUORENYLENEBISACETAMIDE

Hepatoma, X-Irradiation, Accelerated Induction

RADIATION

Hepatoma, N,N'-2,7-fluorenylenebisacetamide, Accelerated Induction

SUBJECT INDEX

- ACETOTOLUIDIDE
AMINOARENZOIC ACID, N-2-FLUORENYLACETAMIDE, CARCINOGEN-INHIBITOR (0041)
- 2-ACETYLAMINOFLUORENE
NITRITE, ANTICARCINOGEN, FREE RADICAL (0042)
- ACTINOMYCIN D
INVASIVE ABDOMINAL CARCINOMA (0024)
- ADENOCARCINOMA
BREAST CANCER, 7,12-DIMETHYLENENAN-THRACENE, ESTROGEN, RAT (0064)
CERVIX UTERI, CHROMOSOMES (0254)
COLON, CARCINOEMBRYONIC ANTIGEN, LOCALIZATION (0235)
NASAL SYSTEM, WOOD DUST (0113)
THYROID, IODINE 131 (0126)
- ADENOMA
LUNG, URETHAN, RADIATION (0101)
MALIGNANT, THYROID, X-RAY (0135)
- AFLATOXIN
B₁, LIVER NUCLEAR RNA, RNA POLYMERASE, RAT (0046)
B₂, LYMPHOCYTE TRANSFORMATION, PHYTOHEMAGGLUTININ (0045)
NUCLEIC ACID SYNTHESIS, INHIBITION (0049)
NURSING MILK, PIG, STUNTED GROWTH (0048)
TUMOR INDUCTION, NUCLEIC ACID BINDING (0047)
- AGE
ADJUSTMENT, EPIDEMIOLOGY, MATHEMATICAL MODEL (0264)
CHRONIC THYROIDITIS, RAT, TRYPAN BLUE (0034)
CORRELATION, LIVER, ALPHA-FETOPROTEIN (0231)
HODGKIN'S DISEASE, HISTOLOGY, TWO ENTITIES (0260)
INOCULATION, MOUSE MAMMARY TUMOR VIRUS, MILK ANTIGEN ASSAY (0104)
WOMEN, SURVIVAL RATE, MAMMARY CARCINOMA (0297)
- AIR POLLUTION
EPIDEMIOLOGY, LUNG CANCER (0016)
- N-ALKYL-4-AMINOAZOBENZENE
AZO DYE BINDING (0056)
- ALUMINIUM
4-NITROQUINOLINE 1-OXIDE, LUNG ADENOMA (0096)
- AMELOBLASTOMA
DENTAL CYST, RAT (0244)
- AMINOAZOTOLUENE
ORTHO-, NUCLEIC ACID BINDING, PROTEIN BINDING (0038)
- BETA-AMINOISOBUTYRIC ACID
BLADDER CARCINOMAS (0336)*
- AMINOSTILBENE
DERIVATIVES, EARLY TUMOR, TRANS-4-DIMETHYLAMINOSTILBENE (0031)
- ANTIBIOTIC
RIBOMYCIN, ORTHOAMINOAZOTOLUENE, LIVER, MOUSE (0025)
- ANTIBODY
FELINE LEUKEMIA VIRUS, VIRAL ANTIGEN (0163)
HODGKIN'S DISEASE, FR VIRUS, HERPES SIMPLEX, CYTOMEGALOVIRUS (0155)
IMMUNOGLOBULINS, IGG, IGA (0229)
MURINE SARCOMA, TUMOR-SPECIFIC ANTIGEN, 3-METHYLCOLANTHRENE (0072)
- PLATELET LEUCOCYTE, TROPHOBLASTIC TUMORS, CHORIOEPITHELIOMA (0227)
SARCOMA, VIRUS, HUMAN (0147)
SV40, PREGNANT HAMSTERS (0213)
- ANTICARCINOGEN
NITRITE, MECHANISM, FREE RADICAL, 2-ACETYLAMINOFLUORENE (0042)
- ANTIGEN
ANTIGENIC ANALYSIS, L STRAIN MOUSE CELLS, MURINE LEUKEMIA-ASSOCIATED (0165)
CARCINOEMBRYONIC, ALPHA-FETOPROTEIN, GASTROINTESTINAL TRACT CANCER, HEPATOMA, TERATOMA (0240)*
CARCINOEMBRYONIC, COLON, ADENOCARCINOMA, LOCALIZATION (0235)
EPSTEIN BARR, VIRUS ENVELOPE, LYMPHOID CELLS (0156)
ERYTHROCYTE ISOANTIGEN, VIRUS SUSCEPTIBILITY, AVIAN LEUKOSIS-SARCOMA VIRUS (0160)
GLYCOPROTEIN, MAMMARY TUMOR AGENT (0191)
IMMUNOFLOURESCENCE, ADENOVIRUS-ASSOCIATED VIRUS, HERPES VIRUS (0179)
LYMPH NODE CELLS, DNA, PHYTOHEMAGGLUTININ (0238)
MILK ANTIGEN ASSAY, MOUSE MAMMARY TUMOR VIRUS, INOCULATION AGE (0194)
RIOUS SARCOMA VIRUS COAT, HETEROKARYOTIC CELLS (0201)
SURFACE AND TUMOR, VIRUS-SPECIFIED DNA, SIMIAN VIRUS 40 (0209)
T, ADENOVIRUS-INDUCED TUMOR, FREEZING TREATMENT (0177)
TUMOR, FRIEND VIRUS, MODIFICATION (0170)
TUMOR SPECIFIC TRANSPLANTATION, ADENOVIRUS, VIRUS INDUCED TUMORS (0180)
VIRAL ANTIBODY, FELINE LEUKEMIA VIRUS (0163)
- AORTA
SWINE, HYPERLIPEMIC DIET, UNDIFFERENTIATED ENDOTHELIAL CELLS (0261)
- APIASIA
HEMATOLOGY, LEUKEMIA, BENZENE EXPOSURE, EPIDEMIOLOGY (0121)*
- ASBESTOS
MALIGNANT MESOTHELIOMA, MINING (0268)
- ATP
ATPASE ACTIVITY, HEPATOMA, PLASMA MEMBRANE OF LIVER CELLS (0259)
NUCLEAR ATPASE LOCALIZATION, MOUSE HEPATOMA (0259)
- AUTOIMMUNE DISEASE
LYMPHOPROLIFERATIVE CHANGE, GERM-FREE MICE (0149)
- BENZENE
CHROMOSOME DAMAGE, BONE MARROW (0030)
LEUKEMIA, EPIDEMIOLOGY (0121)*
- BENZ(a)PYRENE
FIBROSARCOMA, IMMUNOREACTIVITY, RNA (0222)
FIBROSARCOMA, 3-METHYLCOLANTHRENE, PROSIMIANS (0073)
HYDROXYLASE, FLAVONE, PULMONARY ADENOMA (0070)
HYDROXYLATION, INHIBITION KINETICS (0069)
3,4-BENZOPYRENE
LARYNGEAL CANCER, OCCUPATIONAL EXPO-

IURE (0117)*
 LUNG TUMORS, SILICOTIC DUSTS, RAT

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain two-hundred abstracts and twenty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume IX covers the scientific literature published from July 1970 through June 1971. A cumulative subject and author index for Volume IX will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows:

- 0344 THE FUTURE OF CYTOGENETICS. (E.) De Grouchy, J. (Hosp. Child. Dis., Paris, France). *Rev Europ Etud Clin Biol* 15(7):727-728, 1970.

Recent advances in cytogenetics, including the discovery of chromosomal abnormalities associated with overt pathology, have raised the question of the mechanism relating chromosomal imbalance and the corresponding embryonic disorder. In the area of carcinogenesis, the central question is whether the chromosomal abnormalities observed in malignant cells are the cause or the consequence of carcinogenesis. The discovery of an association between the Philadelphia chromosome and leukemia may indicate that there exists a causal relationship between aberrations and neoplastic development. Chromosomal changes in neoplastic cells are apparently not static but evolving, and this clonal evolution may in the case of some malignant conditions (chronic myeloid leukemia) be associated with the clinical development of the condition. New techniques available to the cytogeneticist such as human cell fertilization *in vitro*, *in utero* studies, cell culture and hybridization can be expected to shed much light on these issues. - 0345 AN OPTICAL-RESIDUE SINGLET-OXYGEN THEORY OF PHOTOCARCINOGENICITY. (E.) Khan, A. U. (Inst. Molec. Biophys., Florida State U., Tallahassee) and M. Kasha. *Ann NY Acad Sci* 171(1):24-33, 1970.

A theory of photocarcinogenicity is presented in which the 2 active sites for electrophilic addition, K (adjacent carbon atoms) and L (addition in *para*-positions across the ring), determine only the initial binding of the polycyclic hydrocarbon to the cell constituents. The carcinogenic potency of the molecule is dependent on the generation of singlet molecular oxygen after optical excitation of the optical residue aromatic hydrocarbon. The proposed optical-residue model demands that the residual molecule of a carcinogenic polycyclic hydrocarbon continue to absorb natural sunlight after binding to a cell constituent, that it have a reasonable rate for inter-system-crossing from the singlet excited state to the triplet state, and that the energetic disposition of its electronic states be favorable for singlet oxygen photosensitization. A definite photic effect on benzo[a]pyrene carcinogenesis was noted when painted mice housed in a special darkroom developed 50% fewer gross skin tumors than mice housed in a normally lighted room. Further studies are necessary to determine wavelength dependence, the molecular damage site, and the subcellular biochemical mechanisms involved. (42 references)

- 0346 CELL-CARCINOGEN INTERACTION *IN VITRO*. (E.) Diamond, L. (Wistar Inst. Anat. Biol., Philadelphia, Pa.). *Trans NY Acad Sci* 32(2):234-241, 1970.

Several studies have been conducted to explain the differences in sensitivity to carcinogenic hydrocarbon-induced cytotoxicity evinced by various cell

systems, and several parameters of carcinogen interaction with a variety of cells have been examined. Autoradiographic and fluorescence microscopic studies have shown that resistance to cytotoxicity is not due to the failure of cells to take up the hydrocarbons. However, it has been shown that in cells grown with tritium-labeled 7,12-dimethylbenz(a)anthracene, cytotoxicity-sensitive cells were able to bind 5-50 times more label than were resistant cells; a similar correlation between binding and cytotoxicity was found for 3,4-benzopyrene. Binding of hydrocarbons to cellular macromolecules has been shown to be mediated by microsomal hydroxylase; furthermore, microsomal hydroxylase inhibits hydrocarbon binding in hamster embryo cells pretreated with α -naphthoflavone. α -Naphthoflavone also prevented the inhibition of cell multiplication normally induced by either 3,4-benzopyrene or 7,12-dimethylbenz(a)anthracene. Three parameters of cell-carcinogen interaction in monolayer cultures can be correlated with sensitivity of cells to the induced cytotoxic effect: the presence and inducibility of the microsomal aryl hydroxylase enzyme complex; the metabolism of the hydrocarbon to derivatives which are more water-soluble than the original hydrocarbon; and the binding of the hydrocarbon or its derivatives to cellular macromolecules. In cells resistant to carcinogen-induced cytotoxicity, these activities are absent or reduced, indicating that metabolism of the hydrocarbon is essential for its toxic effect on the cell. Metabolism and binding of a hydrocarbon may also be essential for its carcinogenic effect on cells; experiments to test this hypothesis by determining the efficiency of carcinogen-induced transformation in the presence of α -naphthoflavone are now in progress. Transformation in the presence of α -naphthoflavone of cells normally sensitive to the cytotoxic effect of the carcinogen would suggest that cytotoxicity and transformation are different processes. - 0347 CARCINOGENIC PROPERTIES, STRUCTURE AND REACTIVITY OF PHENOLS. (Rus.) Gubergits, M. Ya. (Chem. Inst. Acad. Sci. ESSR, USSR) and U. E. Kirso. *Vop Onkol* 16(8):96-100, 1970.

The carcinogenic, promoting, toxic and inhibitory effects of phenolic compounds are reviewed in an attempt to establish a quantitative structure-activity relationship. Carcinogenicity is increased by alkyl and halogen substituents which induce an increase of electron density around the -OH group; carcinogenicity is decreased by substituents like -CHO, -COOH and -NO₂ which have the opposite effect. The quantitative correlation between the increase of electron density around the reactive group and the decrease of carcinogenic and promoting activity of phenol compounds is expressed by a modified Hammett-Taft equation. The carcinogenicity of a phenolic compound appears to be related to its nucleophilicity; toxicity and carcinogenicity are negatively correlated, and the toxicity and inhibitory (antioxidant) effects are probably related to the electrophilic properties of the compound. - 0348 TRYPTOPHAN-CARCINOGEN-RESONANCE HYDROPHOBIC PROTEIN BINDING AND CHEMICAL CARCINOGENESIS. (Ger.) Franke, R. (Inst. Physiol. Biol. Chem., Humboldt U., Berlin, Germany). *Arch Geschwulstforsch* 36(1):30-33, 1970.

The Birks theory that there is a correlation between carcinogenic activity and the tryptophan overlap integral (J_1), subject to the formation of protein complexes by the hydrocarbons is considered. This theory has been criticized on the grounds of quantum mechanics, but without taking into account complex formation with proteins. A suitable dimension for the characterization of complex formation between protein and carbohydrate is, as shown previously, the logarithm of the binding constant for the binding of carbohydrate to human serum protein, $\log K_B$. A rank correlation statistical analysis was carried out to find the correlation between J_1 and carcinogenic activity by means of the protein binding and thus to reevaluate the Birks theory. The results proved that the correlation between carcinogenic activity and overlap integrals had no real physical significance. (9 references)

- 0349 SUSCEPTIBILITY TO TRANSFORMATION. (E.) Anonymous *Nature* 228(5276):1032, 1970.

Experiments have been designed to investigate the possibility that persons whose cells are especially susceptible to *in vitro* transformation by SV40 are persons at a high risk of developing cancer. Studies have shown that human cells which are differentially susceptible to infection by SV40 particles are equally susceptible to infection by SV40 DNA alone, a result suggesting that relative resistance or susceptibility to SV40 infection depends on a block or the lack of a block to an early event in infection. This hypothesis is further supported by the finding that, in cells infected with SV40 DNA, all cells have similar tumor-antigen contents and similar rates of transformation, while in cells infected with virus alone, cells having the highest tumor-antigen contents are the cells with the highest rate of transformation. Other experiments further suggest that transformation of infected cells and the production of tumor-antigen are closely related processes. (2 references)

- 0350 NEW GROWTH AND VIRUSES. (E.) Stoker, M. (Imperial Cancer Res. Fund Lab., London, England). *Brit Med J* 3(5722):541-545, 1970.

Characteristics of growth regulation were studied in individual normal cells (3T3 mouse cell line and BHK21 hamster cell line) and compared with those in polyoma-transformed cells. A high cell density causes normal cells to stop growing in the G_1 phase unless the density is reduced; preventing cells from anchorage to a rigid surface stops growth. Protein associated with the gammaglobulin fraction of serum is a requirement for growth although this factor (or factors) is not species specific in its effect. Addition of fresh serum to resting confluent cultures of 3T3 cells causes further growth, but the

probability that a particular cell will respond depends on its topography (position in relation to other cells) so that a free cell in a wounded area may be 8 times more sensitive to serum than a cell in an undisturbed sheet. Transformed cells are less sensitive to density-dependent inhibition and continue to grow in thick layers freely in suspension without contact to a rigid surface. The transformed cells can continue one or two mitotic divisions in serum levels inhibitory for normal cells, while DNA synthesis continues until the cells degenerate without undergoing mitosis. (30 references)

- 0351 VIRAL ETIOLOGY OF CANCER, LEUKEMIA AND ALLIED DISEASES. (E.) Gross, L. (VA Hosp., Bronx, N.Y.). *CA* 20(4):243-247, 1970.

Experimental observations supporting the hypothesis that latent oncogenic virus are present in many normal and healthy hosts and can be activated by a "oncogenic situation" are reviewed. Studies have shown that oncogenic viruses (e.g., Rous chicken sarcoma virus) found originally in one species may be pathogenic for other species, and that certain viruses which are latent in one species may be oncogenic for other species (e.g., SV40 which is latent in the rhesus monkey causes sarcomata in hamsters). In instances of radiation-induced leukemia in mice, the leukemic tissues of these mice were found to harbor a filterable leukemogenic virus. In addition, leukemia and lymphoma viruses found in leukemic mice, produce leukemia in other mice and in rats when transferred from the original host. These latent oncogenic viruses which may be normally present in large numbers of individual animals and humans become pathogenic only when activated by some trigger such as irradiation, chemical carcinogens, or metabolic or hormonal factors. The presence of an inactive but potentially oncogenic virus in healthy humans might be indicated by the individual's family record; those with family histories of carcinoma or leukemia may harbor inactive viruses. (60 references)

- 0352 FOOTPRINTS OF HUMAN CANCER VIRUSES? (E.) Anonymous. *Nature* 228(5275):907-908, 1970.

The discovery that human leukemic cells harbor reverse transcriptases which use RNA as the template for DNA synthesis can be interpreted as evidence that at least some human cancers have a viral etiology. Experiments by Gallo, Yang, *et al* have shown that antibodies against group specific antigens of murine sarcoma virus inactivate the reverse transcriptase in murine sarcoma virus and other viruses; should these antibodies also inactivate human leukemia polymerase activities, strong evidence would be provided that human leukemia viruses do exist. The only trace of such human viruses may be these reverse transcriptases. Related experiments by Pollack *et al* have suggested that an increase in number of chromosomes in some cells accompanies a loss of several of the characteristics of the malignant transformed condition. These results may indicate that relapses in symptoms of malignancy fol-

(0353-0356)

lowing an initial improvement occur because hyperploid cells give rise to cells with low chromosome numbers which are especially susceptible to malignant transformation. (no references)

0353 INFECTIOUS MONONUCLEOSIS: RECENT DEVELOPMENTS. (E.) Banatvala, J. E. (St. Thomas' Hosp. Med. Sch., London, England). *Brit J Haemat* 19(2):129-133, 1970.

Evidence for a causal association between Epstein-Barr virus and infectious mononucleosis is not conclusive, despite the fact that the virus is a commonly encountered infectious agent which is associated with Burkitt's lymphoma. One study has shown that only those members of the study group whose sera were negative for Epstein-Barr virus antibodies developed infectious mononucleosis. Furthermore, following the onset of illness, titers of virus antibodies rose significantly to 40-640. Epstein-Barr virus antibodies are of global distribution, and their presence is correlated with factors such as age and socio-economic status. Young children have been found to be antibody seropositive in 50-80% of test populations; those of low socio-economic status are more often positive than those of other levels. Evidence that Epstein-Barr virus causes infectious mononucleosis is provided by the fact that antibodies to the virus appear to protect against infectious mononucleosis. Moreover, almost all patients with infectious mononucleosis develop high or rising titers of Epstein-Barr antibodies during the course of their illness. The virus has been shown to replicate only in the cells of the lymphoreticular system and to stimulate leukocytes of patients with infectious mononucleosis to proliferate into blastoid cell cultures which harbor Epstein-Barr virus. (20 references)

0354 IMMUNOLOGICAL DISORDERS IN THE ETIOLOGY OF LYMPHORETICULAR NEOPLASMS. (E.) Hoerni, B. (Bergonie Found., Bordeaux, France) and G. Laporte. *Europ J Clin Biol Res* 15(8):841-850, 1970.

Data implicating immunological factors in the development of lymphoreticular neoplasms and suggested mechanisms for the immunological initiation of growth are reviewed. Congenital or acquired (thymectomy, chemical carcinogens, or immunosuppressive drugs) immune deficiencies as well as immunoproliferative disorders apparently increase the frequency of malignant lymphomas in animals. An autoimmune disease found in NZB/B1 mice and minks preceded the development of lymphoma, while spleen cell grafting and repeated mineral oil (or antigen) injections led to malignant lymphoid tumors. Similar findings in man showed that immunological deficiencies (agammaglobulinemia) and lymphoproliferative disorders (systemic lupus erythematosus) resulted in increased incidence of lymphomas. Viruses may become infectious in an immunologically deficient environment, and repeated infections produce an increased proliferation of lymphoreticular cells with higher risks for neoplastic mutation. If a neoplastic clone undergoes proliferation, the antibodies produced against the transformed cells

(7S antibodies) may actually be enhancing antibodies, and certain viruses may produce transformed cells or neoantigens which are histochemically similar to the host cells, resulting in cancerous proliferation even with normal defenses. Evidence for the importance of immunological factors in carcinogenesis is increasing. (124 references)

0355 THE CONCEPT OF IMMUNOLOGICAL SURVEILLANCE. (E.) Burnet, F. M. (U. Melbourne, Parkville, Victoria, Australia). *Progr Exp Tumor Res* 13:1-27, 1970.

The concept of immunological surveillance (the immunological mechanism present in large long-lived animals for eliminating or inactivating the potentially dangerous mutant cell produced through inheritable genetic changes which must be common in somatic cells) was examined. Implications of such a concept are that the incidence of malignancies initiated during immunity deficiency will be high, that pathological conditions associated with depression of the thymus-dependent immune system should be associated with increased likelihood of neoplasia, that late activity of the immune system might occasionally cause spontaneous regression of tumors, and that more histologically observable foci of cancer than could ever develop to definite tumors should be observed at autopsy of cancerous organs. Representative studies that have been conducted on the effects of immunosuppressive agents, neonatal thymectomy, fetal or perinatal tolerance, immune paralysis, and specific resistance to tumor implantation suggest that the concept of surveillance is valid. The hypothesis for the evolution of adaptive immunity (responses to the development of parasitism by early cyclostomes on hosts of similar character) and a similar modification of genetic control leading to the appearance of cancer may substantiate the evolutionary principle that the new mechanism of immunity was further refined for use against the new danger. (82 references)

0356 CONTROL OF NEOPLASIA BY IMMUNOLOGICAL MEANS: AN ASSESSMENT OF A NEW APPROACH. (E.) Plescia, O. J. (Inst. Microbiol., Rutgers U., New Brunswick, N. J.) and W. Braun. *G Batt Virolog Immun* 63(1-6):7-18, 1970.

Attempts have been made, based on theoretical considerations concerning host receptivity for a tumor, to develop a method for the preparation of effective tumor vaccines. Theoretically, a host may fail to reject a syngenic tumor possessing tumor-specific transplantation antigen for any of the following reasons: the tumor is not sufficiently foreign antigenically to elicit an adequate immune response; the tumor is not subject to biological control and therefore can develop beyond the control of a normal immune response; because of its location, the tumor may elicit a humoral, rather than cell-mediated response; the host may become specifically tolerant to the tumor or generally unresponsive as a result of immunosuppression caused

by oncogens or by the aging process. Experimental results in the development of a tumor vaccine based on this analysis have attempted to make tumor tissue more foreign antigenically by conjugating it to a "carrier" such as agents of the dinitrophenyl group or methylated bovine serum albumin. Tumors treated in this way, implanted s.c. in hosts, are effective as a vaccine and promote rejection of challenge tumor cells. The vaccine efficacy increased when an adjuvant was used to enhance the host response. Although such vaccines have proved effective prophylactically and therapeutically, a dearth of knowledge concerning the etiology of spontaneous tumors and tumor-specific transplantation antigens renders tumor vaccines feasible only as adjunct therapy following surgery as a means of controlling residual tumor tissue development. (29 references)

- 0357 IMMUNOSUPPRESSION AND NEOPLASIA. (E.) Balner, H. (Radiobiol. Inst. TNO, Rijswijk, Z.H., Netherlands). *Europ J Clin Biol Res* 15(6):599-604, 1970.

Prolonged immune deficiency has been shown experimentally to be a factor which contributes to susceptibility to oncogenic viruses and to carcinogens that induce tumors with a rather high tumor-specific antigenicity. In most experiments the immune-deficient state was achieved by conventional immunosuppressive agents (Imuran and steroids, whole body irradiation, alkylating agents, antimetabolites), early thymectomy or treatment with anti-lymphocyte serum. More recently, it was also reported that the tumor incidence in transplant patients under chronic immunosuppressive treatment is significantly higher than in comparable control individuals. No evidence was found that the role of anti-lymphocyte serum in the breakdown of a hypothetical surveillance mechanism against neoplasia was different from that of conventional immunosuppressive agents. Immunosuppression seems to enhance the susceptibility to oncogenic factors in animals by interfering with cellular defences. (39 references)

- 0358 THE ROLE OF IMMUNOLOGY IN HUMAN CANCER RESEARCH. (E.) Gold, P. (Montreal Gen. Hosp., Quebec, Canada). *Canad Med Ass J* 103(10):1043-1051, 1970.

Ethical limitations on human experimentation and wide genetic diversity of the population have made research of human cancers difficult, but the evidence of tumor-specific transplantation antigens in a wide variety of experimental tumors in animals and modern technology have resulted in the detection of tumor-specific antigenicity in some human tumor systems. The carcinoembryonic antigen of the human digestive system and α -fetoprotein in hepatomas as well as characteristic immune reactions observed with sera of patients with Burkitt's lymphoma, malignant melanoma, osteosarcoma and neuroblastoma are examples of recent cancer immunology research. Some of these systems apparently stimulate an immunologic response by the cancer patient, suggesting that where cancer growth has developed the defense mechanism has been over-

whelmed or is defective. Application of the tumor-specific antigenicity to cancer diagnosis has been encouraging and immunotherapy for cancer patients is being investigated. (83 references)

- 0359 A REAPPRAISAL OF THE "MYELOPROLIFERATIVE DISEASE" CONCEPT. (E.) Gilbert, H. S. (Mount Sinai Sch. Med., City U., New York, N. Y.) *Mount Sinai J Med* 37(4):426-435, 1970.

The trend toward subsuming such disorders as polycythemia vera, agnogenic myeloid metaplasia, essential thrombocythemia, erythroleukemia, and chronic myelocytic leukemia under the single rubric of "myeloproliferative disorders" is a relatively recent one and has supplanted an earlier tendency to regard each of these conditions as a separate disease entity. The rationale for unifying these various diseases in a single category was the existence of a hypothetical precursor cell with the potential for developing into cells of the erythroid, myeloid or megakaryocytic series. Recent (1961) it has been shown that such a pluripotential stem cell does in fact exist, and the development of techniques for karyotyping cells have supported the hypothesis that there is a common ancestor cell for erythroid and granulocyte cells by showing that the abnormal Philadelphia chromosome is present in both erythroid and myeloid precursor cells. However, both genetic and biochemical studies have recently cast doubt on the feasibility of regarding all the "myeloproliferative diseases" as members of 1 nosologic family. The continuing failure to demonstrate the Philadelphia chromosome in polycythemia vera during its various stages, the differences in levels and behavior of leucocyte alkaline phosphatase activity in all myeloproliferative conditions, and the failure to observe transitions in the karyotype or enzyme picture despite apparent clinical transition from polycythemia vera to a picture resembling chronic myelocytic leukemia, tend to polarize at least 2 the members of the myeloproliferative syndromes chronic myelocytic leukemia being set apart from polycythemia vera. The remaining entities included in the group would appear to segregate with polycythemia vera on the basis of current knowledge. (34 references)

- 0360 THYMIC TUMORS, ASSOCIATED GENERAL SYNDROMES AND CARCINOGENESIS. (Fr.) Saeges F. (Fac. Med. Lausanne, Switzerland) and G. Zoupas. *Entretiens Bichat* 49-56, 1970.

Recent clinical and experimental data indicate that patients subjected to organ transplants become susceptible to malignancy of the immunopoietic system. The frequent coexistence of thymoma and general immunological disorders such as myasthenia gravis, aplastic anemia, acquired hypogammaglobulinemia, collagenoses and autoimmune diseases indicate that the thymus is a key organ in both the development and maintenance of the immunological potential of the organism. A high incidence of lympho-epithelial thymoma is predicted for long-surviving patients with organ transplants. (no references)

0361 TUMOR SPECIFIC ANTIGENS ASSOCIATED WITH CHEMICALLY INDUCED TUMORS. (E.) Baldwin, J. W. (British Empire Cancer Campaign Res. Lab., U. Nottingham, England). *Europ J Clin Biol Res* 5(6):593-598, 1970.

Chemically-induced tumors frequently possess new antigens, which have been described as tumor-specific transplantation antigens because of their capacity to elicit rejection responses against transplanted tumor cells in syngeneic hosts. Tumor-specific antigens with identical specificities have been demonstrated in some cases by *in vitro* interaction of tumor cells with humoral antibody or sensitized lymphoid cells. These antigenic specificities differ from those of antigens on virus-induced tumors where cross-reactivity is a common feature. It is now evident, however, that virus-induced tumors may also have tumor antigens with individual specificities. Tumor-specific antigens in chemically-induced tumors can be considered as expressions of new genetic specificities induced by the carcinogen. Definition of their frequency of expression in tumors may, therefore, indicate the number of cellular receptors modified during chemical carcinogenesis. Although there is no evidence that these antigens play any direct role in neoplastic transformation, other than their influence in displacing the array of normal cell surface antigens, they undoubtedly affect tumor growth potential. (67 references)

0362 RECENT ADVANCES IN IMMUNOLOGIC DIAGNOSIS OF DIGESTIVE CANCER. (E.) Zamcheck, N. (Boston City Hosp., Mass.) and A. Stillman. *Amer J Dig Dis* 15(11):1003-1018, 1970.

Immunologic methods have been developed which can detect minute amounts of antigens which are specific for several cancers of the digestive system; these antigens include α -fetoglobulin, carcinoembryonic antigen, gastric juice sulfoglycoproteins, and "tumor glycolipids." α -Fetoglobulin has been detected in the serum of 68% of patients with hepatomas in 1 study; only 3.1% of patients without hepatoma who had other neoplasms were α -fetoglobulin-positive. It is common, however, for patients with hepatomas not to exhibit α -fetoglobulin. The frequency of α -fetoglobulin associated with hepatoma may be related to the agent inducing the tumor. Fewer Caucasian patients with hepatoma produce α -fetoglobulin than non-Caucasian patients; and newborn animals synthesize α -fetoglobulin only in negligible amounts. Carcinoembryonic antigen was found associated with tumors originating in the endodermally derived epithelium of the digestive system; cancers of the colon and rectum were most frequently involved, but duodenal tumors, stomach tumors, and tumors of the esophagus also showed concentrations of carcinoembryonic antigen. Studies have shown carcinoembryonic antigen in 97% of patients with colonic or rectal carcinomas. Gastric sulfoglycoproteins have been detected in 96% of patients with gastric cancer in 1 study; however, gastric sulfoglycoproteins are also found in patients with benign peptic ulcers, a finding which

limits the clinical usefulness of the antigen for diagnostic purposes. "Tumor glycolipids", specifically cytolipin G, have been found in tissues and tumors of the gastrointestinal tract. (112 references)

0363 DERMATOGLYPHICS IN LEUKEMIA. (E.) Rosner, F. (Maimonides Med. Ctr., Brooklyn, N.Y.). *Lancet* 2(7678):882-883, 1970.

Of 9 recent studies of the correlation of dermatoglyphic features and leukemia, 5 have reported that leukemic patients show significantly different dermatoglyphic characteristics than normal subjects; the differences usually involved increased radial loops and/or whorls on the fingers of leukemic patients and increased simian or Sydney lines on their hands. Two studies, however, reported that there was no difference between dermatoglyphic patterns in leukemia patients and in normal subjects and that data on specific dermatoglyphic parameters in leukemic patients and normal subjects are contradictory. It seems premature to conclude, on the basis of dermatoglyphic peculiarities, that there is evidence for a genetic or teratogenic factor controlling both leukemia and dermatoglyphic patterns. (14 references)

0364 LEUKEMIA IN TWINS: WORLD-WIDE REVIEW OF CLINICAL CASES. (E.) Keith, L. (Chicago Med. Sch., Ill.) and E. Brown. *Acta Genet Med Gemellol* 19(1-2):66-68, 1970.

From an extensive review of world-wide clinical reports of leukemia in twins, 62 cases were compiled and examined. Leukemia occurred in the Perinatal-Congenital period (birth to 1 yr) in 15 cases, in the Early Childhood period (2-7 yr) in 26 cases, in the Late Childhood period (7-12 yr) in 9 cases, and in the Adult period (remaining years) in 12 cases. Leukemia occurred in monozygous (MZ) twins in 39 cases (21 cases of concordance and 18 of discordance), in dizygous twins (DZ) in 13 cases (4 cases of concordance and 9 of discordance), and in the remaining 10 cases the zygosity was doubtful. Discordance became more prevalent in the later periods with the concordance-discordance ratio decreasing in MZ sets (10:1, 6:6, 1:5, and 4:6) and in DZ sets (1:1, 3:5, 0:1, and 0:2) for the Perinatal-Congenital, Early Childhood, Late Childhood and Adulthood periods, resp. (5 references)

0365 CANCER IN TWINS: CONCORDANCE OR DISCORDANCE? (E.) Keith, L. (Chicago Med. Sch., Ill.) and E. Brown. *Acta Genet Med Gemellol* 19(1-2):61-64, 1970.

Published reports (1940-1964) of cancer in twins were reviewed to point out the obvious limitations to concordance studies. Conclusions within publications from the same institution changed according to the period of observation. Materials and methods for determining zygosity were sometimes questionable, and the possibility that not all cases of

cancer in twins were reported must be considered. Small numbers of cases with categorized sites and types of tumors were used to produce general support for the theory that genetic factors operate either in the concordance of cancer on in the site of the specific tumors. Type, site, and age at onset of tumors apparently affected monozygous twins more frequently than both members of a dizygous pair. The exact genetic influence on concordance or even in the development of malignant growths is doubtful. (15 references)

- 0366 DIAGNOSIS AND THERAPY OF THOROTRAST-INDUCED TUMORS. (Ger.) Beckenbach, H. (German Cancer Res. Ctr., Heidelberg), G. Van Kaick and W. Wenz. *Z Krebsforsch* 74(4):318-328, 1970.

The late effects of thorotrast administration are reviewed through the available literature and the author's clinical experience (300 patients). Among the factors contributing to its effects are its long half-life (1.39×10^{10} yr), its radioactive emission products (90% α -, 9% β - and 1% γ -radiations), the accumulation of 15 μ -sized thorium dioxide particles and its failure to be excreted from liver, spleen, bone marrow and lymph nodes. Late effects included fibroses at the injection site after defective paravascular administration, diseases of the hematopoietic system (leukocytoses), and the occurrence of tumors 10-20 yr after thorotrast administration. The liver is considered to be the most susceptible organ to thorotrast carcinogenesis, accumulating approximately 50% of the intravascularly administered substance. Accumulation occurred mainly extracellularly in the area of Glisson's sheath, and led to liver cell carcinoma and bile duct carcinoma. (18 references)

- 0367 CANCER HAZARDS IN THE LABORATORY. (E.) Anonymous. *Brit Med J* 3(5718):298-299, 1970.

Hazardous carcinogenic compounds encountered by laboratory workers in the course of their duties include α - and β -naphthylamine, benzidine, 4-aminodiphenyl, orthodiansidine, 4-nitrodiphenyl, orthotolidine and salts of these compounds. High incidences of bladder cancer among laboratory workers who handle these chemicals on a large scale are suggested by an increasing number of individual case reports, and occupational exposure to carcinogenic compounds is implicated. A study of 3,367 death certificates of chemists showed that among male chemists from 20-64 yr-of-age, there were 444 deaths from cancer compared to 354 expected cancer deaths; 41 of the excess deaths were attributed to malignant lymphoma or to cancer of the pancreas. However, the above study did not find a significant excess of deaths from cancer of the urinary bladder, but the number of cases expected and found were small. (8 references)

- 0368 CANCER IN GYNECOLOGY AND OBSTETRICS. (Fr.) Simard, R. (Hosp. Notre Dame, Montreal, Quebec, Canada). *Un Med Canada* 99(11):2047-2050, 1970.

Epidemiological features of cervical cancer such as its higher incidence among the economically less privileged and among women of minority races, its association with sexual activity, vaginal infection and early marriage, its high frequency among prostitutes and its absence in the virgin female are reviewed. The incidence of this malignancy in Canada is highest in the Province of Quebec (according to 1967 data), where it approaches the incidence of cardiovascular diseases. The importance of detection of this disease in the preclinical stage is emphasized. (22 references)

- 0369 THE PROBLEM OF CARCINOMA OF BILHARZIAL BLADDER IN IRAQ: CRITICAL REVIEW. (E.) Talib, H. (Baghdad U., Iraq). *Brit J Urol* 42(5):571-579, 1970.

The incidence, clinical features, and treatment of carcinoma of the bladder and the correlation with bilharziasis among the inhabitants of Iraq is reviewed. Of 78 patients with carcinoma of the bladder evaluated during the past 3 years, 39 were squamous cell carcinoma (10 with bilharziasis), 2 were transitional cell carcinoma (2 with bilharziasis), and 9 were undetermined. The predominance of a bilharzial history with squamous cell tumor and the occurrence of only transitional cell tumor in patients from northern regions where bilharziasis is rare suggest the chronicity of a process which ultimately gives rise to metaplastic changes in bladder epithelium. The primary symptom was hematuria, but dysuria, increased urinary frequency, and renal colic were also observed. Treatment was based on several factors (the patient's condition and renal function, the stage of the illness, and coincidence of other diseases) and included surgery, transurethral resection, interstitial radiation, ray therapy, and chemotherapy. (13 references)

- 0370 CONSIDERATIONS CONCERNING RADIATION RISKS. (Ger.) Wachsmann, F. (Soc. Radiation R., Munich, Germany) *Radiologe* 10(9):345-353, 1970.

Difficulties in determining the optimal dosage of radiation in medical practice are discussed. Of particular concern are radiation-induced malignant tumors, such as thyroid gland and skeletal tumors, leukemias, genetic damage, injury to the embryo and other harmful consequences of radiation. The linear relationship of dose effect to damage is established, although the frequency of damage induced by radiation increases with the dose. A problem which has not been entirely solved is the question of the cumulative effects of radiation. It is recommended that the effects of accumulated doses should be taken into account in treatment. The risk of leukemia is particularly prominent in radiologists, and also in patients whose treatment necessitated radiation. On the other hand, it is of interest to note the low frequency of leukemia in children whose mothers were exposed to radiation during their pregnancies. The atomic bomb explosion in Japan precipitated many malignant tumors in older people, far outnumbering those found in the young. Other effects of exposure to whole body radiation are discussed. (35 references)

0371 RIOPELLE'S TUMOR: II. HISTOGENESIS AND CONCLUSIONS. (Fr.) Roujeau, J. (Hosp. Pariboisiere, Paris, France) and A. Galian. *Ann Anatol* 4(3):149-157, 1970.

The theories on the histogenesis of Riopelle's tumor are reviewed and illustrated by morphological data obtained from dimethylnitrosamine-induced kidney tumors in rats and by an analysis of kidney embryology. The classical theories attributing an embryonic origin to these tumors due to their morphological resemblance to embryonic renal tissue are being challenged by more recent views attributing a neural origin to these tumors. This latter view is supported by the frequent occurrence of primary nerve tumors in the kidney. It is concluded, however, from the morphological data, that Riopelle's tumor constitutes an adult equivalent to Wilms' tumor, possibly originating from a single cell strain endowed with a double epithelial and connective tissue potentiality. (49 references)

0372 HORMONE PROFILES AND DISCRIMINANT FUNCTIONS IN CANCER. (E.) Anonymous. *Lancet* 2(7682):1070-1071, 1970.

Various studies have attempted to determine hormonal factors which constitute "discriminant functions" in a compiled statistical data on the clinical pictures presented by cancer patients. A particular variable analyzed is said to be a discriminant function if it effectively picks out cancer patients from controls and accentuates the differences between them. It has been shown that high etiocholanolone relative to 17-hydroxycorticosteroids is a discriminant function for patients with advanced breast cancer; in a related study, corticotrophin-stimulated levels of urinary 17-oxosteroids and 17-hydroxycorticosteroids successfully separated cancer patients responsive and unresponsive to adrenalectomy. In patients with breast, prostate and lung cancer effective discriminants have been based on gonadotrophin, estriol and androsterone values. Abnormal urinary excretion of such hormones as androsterone, etiocholanolone, and pregnanediol discriminate lung cancer patients from well and emphysematous controls. The findings of hormonal abnormalities associated with cancer suggests that the following factors contribute to the overall hormonal profile of patients: underlying endocrine abnormalities which arise independently of the onset of cancer; effects of illness as the disease progresses; and tumor metabolism. 0373 NASAL PAPILLOMATOSIS. (E.) Kusiak, R. J. (Durham, N. C.) and W. R. Hudson. *Southern Med J* 63(11):1277-1280, 1970.

The histology and pathogenesis of nasal papillomas were investigated in a review of the literature of this condition and in a survey of hospital cases. Nasal papillomatosis comprises 5 conditions, including common polyp (or soft papilloma), papillary squamous cell carcinoma, hyperkeratotic papillary growths, septal papillomas and inverted papillomas.

Hyperkeratotic tumors arose only from the stratified squamous epithelium of the nasal vestibule, while the other lesions were derived from the pseudostratified columnar epithelium lining the nasal cavity. Both septal and inverted papillomas were covered by epithelium ranging in type from columnar to squamous; hyperplastic epithelium in inverted papilloma tended to grow inward simulating stromal invasion. In more malignant papillomas, the underlying soft tissue or the bone was invaded. Nasal papillomatosis is a rare condition which usually arises in men during their fifth or sixth decade. The etiology of nasal papillomas is unclear, but there is evidence for a viral agent. (19 references)

0374 MIXED CALCIFIED ODONTOGENIC TUMORS. (E.) Stasinopoulos, M. (Athens, Greece). *Brit J Oral Surg* 8(1):93-100, 1970.

The classification and development of mixed calcified odontogenic tumors were examined on the basis of a study of 201 cases and a review of the relevant literature. The thesis that these tumors result from trauma was rejected, as only 4 of the 201 cases studied had any relation to trauma. Mixed calcified odontogenic tumors develop during the period of odontogenesis only; no case was found where tumors developed after this period. Of 190 cases, 103 were males and 87 females. Tumors classified as complex composite odontoma showed a predilection for the area of the lower molar teeth (35 cases), while compound composite odontoma were most common in the region of the upper anterior teeth (55 cases). On gross examination odontoma showed atypical calcified masses or clusters of denticles, while microscopically, tumors were composed of enamel and 1 or more of the other dental tissues. Tumors rarely affected the first or deciduous teeth (4 of 201 cases), and often showed a prolonged latent period intervening between development and onset of presenting symptoms, which included pain and swelling. (34 references)

0375 PUBERTY AND CANCER. (E.) Anonymous. *Brit Med J* 3(5725):722-723, 1970.

The peak in the death rate for acute myeloid leukemia at age 17 in males and somewhat earlier in females may be attributed to the accelerated bone growth in adolescence. However, it may be that the peaks in myeloid leukemia deaths during adolescence represent an acceleration of a carcinogenic process which, without increased bone growth in adolescence, would have proceeded at a more leisurely pace and manifested itself later in life. It is not clear whether reports of peaks in death rates from neuroblastomas, Wilm's tumor, and lymphatic leukemias in children and mothers exposed to x-rays during pregnancy correspond to periods of maximal bone growth. The observed peaks in death rates following puberty may result from temporary alterations in the body's defenses against carcinogens to which it had been exposed caused by rapid growth at puberty. (4 references)

- 0376 CAMPAIGN AGAINST CANCER. (E.) Anonymous.
Brit Med J 3(5715):118-119, 1970.

A brief digest of the contents of the 47th Annual Report of the British Empire Cancer Campaign surveys carcinogenesis research presently going forward under the auspices of the Campaign. It has been demonstrated that some carcinogens, administered during pregnancy, are teratogenic; however, a close association between carcinogenesis and teratogenicity is not apparent. An examination of children with solid tumors in one London hospital has shown that, apart from an increase in malformations of the lower gastrointestinal and urinary tracts in patients with sacrococcygeal teratoma, none of the groups of neoplasms was associated with a conspicuous increase in congenital abnormality. Another study has demonstrated that infection with a mycoplasma renders rats susceptible to the stimulation of cell proliferation in the tracheobronchial epithelium by tobacco smoke. The antitumor activity of 5-aziridino-2,4-dinitrobenzamide against certain transplantable tumors may or may not be of clinical significance. The enzyme L-asparaginase derived from *E. coli* has been shown to be effective in lowering the blast cell count in patients with acute myeloid or acute lymphoblastic leukemia. Males with Klinefelter's syndrome may have a 20-fold increase in incidence of breast cancer compared to the normal population, a conclusion based on a study of 68 cases of Klinefelter's syndrome. Detritus from 2 vitallium articulatory surfaces rubbed together mechanically in Ringer's solution gave rise to a rhabdomyosarcoma after intramuscular injection in rats. Eighty percent of biopsy specimens taken some distance from transitional-cell carcinomas of the bladder showed changes which were interpreted as precancerous. (3 references)

- 0394 IMMUNOGLOBULIN CHANGES IN MICE WITH EXPERIMENTAL PLASMACYTOMA. (E.) Hashimoto, N. (Jikei U. Sch. Med., Tokyo, Japan). *Acta Haem Jap* 33(1):16-27, 1970.

The changes in immunoglobulin in mice with experimentally induced plasmacytoma (Freund's adjuvant, i.p.) were followed by immunoelectrophoresis. Sixteen wk after the first injection of adjuvant, the immunoglobulins in the sera showed bifurcation of the γ -precipitin line in the β -region, extending anodally (mid- γ bifurcation) in only 9 out of 20 animals; after 20 wk, 18 out of 19 animals showed this mid- γ bifurcation with 1 animal evidencing abnormal precipitin lines. At this stage (20 wk) plasma cells were inflammatory and reactive. After 42 wk, 3 mice showed the monoclonal pattern identified as M-component and excreted Bence Jones protein in the urine, and the plasma cells were atypical. Blood taken periodically (retro-orbital puncture of the ophthalmic venous plexus) from mice indicated that at 36 wk the bifurcation of 7S γG_1 and 7S γG_2 precipitin lines was evident, and at 42 wk the 7S γG_1 precipitin line increased while the 7S γG_2 became dimmer; at 44 wk the M-component seemed to be formed.

- 0395 DEVELOPMENT OF PLASMA CELL TUMOR IN BALB/c MICE: FROM CYTOHISTOLOGICAL ASPECTS. (E.) Okazaki, E. (Niigata U. Sch. Med., Japan). *Acta Haem Jap* 33(1):28-36, 1970.

The cytohistological development of plasma cell tumors (induced by Freund's complete adjuvant mixed with bacterial α -amylase or Taka-amylase, i.p.) was observed in 20 BALB/c mice. The predominant tumor cells fell into 3 distinct classes (mature plasma cells, anaplastic plasma cells, and reticulum cells), and no definite correlations between the monoclonal immunoglobulins synthesized and the class of cells could be made. Three of the animals exhibited plasma-cellular lesions in the early stages of development. The neoplastic cells were polygonal in shape with round or ovoid nuclei centrally located and were surrounded by delicate reticulin fibers. Chronological observations at 1 wk intervals after injection with the antigen-adjuvant mixture disclosed scattered opaque spots on the peritoneal surfaces after 1 wk and small granulomatous lesions over the peritoneal and mesenchymal surfaces after 2 wk. After 5 wk mesenchymal cells (possibly histiocytic in origin) were found in clusters among the fatty droplets in the oil granulomas; after 8 wk round cells with large round nuclei and abundant pale blue cytoplasm, and round cells with eccentric chromophilic nuclei and dark blue cytoplasm were observed as well as leucocytic and lymphocytic cells.

- 0396 VIRUS-LIKE PARTICLES IN DEVELOPING PLASMA CELL TUMORS INDUCED IN BALB/c MICE. (E.) Scholle, R. H. (Walter G. Zoller Mem. Dent. Clin., U. Chicago, Ill.) and J. W. Foft. *Exp Molec Path* 13(2):147-158, 1970.

Virus-like particles were detected early in plasma cell tumors induced in BALB/c mice by mineral oil

injections. Mice were given 1 or 3 i.p. injections of 0.5 ml mineral oil at 1-4 months of age. Electron microscopic examination of an oil granuloma 1 animal revealed intracisternal A-type virus-like particles 12 days after 1 oil injection. Particles approximately 70 m μ in diameter with a doughnut shape with an electrolucent core were found in blast cells. In a second animal killed 12 wk after an injection of oil, particles were found in blast cells and in mature plasma cells. Neither the mice harboring virus-like particles had ascites and neither had definite plasmacytomas. In both cases, particles were seen budding from the endoplasmic reticulum of cells. The induced granulomatous tissue in which particles were found may provide a favorable environment for the morphological expression of an incomplete viral genome which be present in all mice of the strain tested. An etiologic role for viruses is suggested by the association of these particles with neoplastic plasma cells.

- 0397 INVESTIGATION OF BIOSYNTHETIC FORMATION OF POLYCYCLIC HYDROCARBONS IN HIGHER PLANTS. VIII. CARCINOGENIC HYDROCARBONS IN THE MAN-MADE ENVIRONMENT. (Ger.) Grimmer, G. (U. Hamburg, Germany) and D. Düvel. *Z Naturforsch* 25(10):1171-1175, 1970.

In order to study the environmental contribution to the carcinogenic chemical contents in plants, the polycyclic hydrocarbon levels in lettuce, rye, bean and tobacco plants grown outdoors, in a no greenhouse, and in a controlled climate chamber (fine dust and gas filtered air) were compared. The results demonstrated that none of the 7 polycyclic hydrocarbons (benzo(e)pyrene, benzo(a)pyrene, perylene, anthracene, benzo(ghi)perylene, dibenz(a,h)anthracene and coronene) tested for appearance in the plants grown in the controlled climate chamber. The plants grown both outdoors and in greenhouse from the same seeds showed considerable quantities of these carcinogens, although the controlled climate chamber was situated within a distance of 100 m from the other two test areas. Lettuce and soybeans had approximately 4 μ g/kg benzo(a)pyrene and similar levels of benzo(a)pyrene; rye had 3.4 μ g/kg benzo(e)pyrene and 1.6 μ g/kg benzo(a)pyrene; and tobacco plants had 2.5 μ g/kg benzo(a)pyrene and 1.8 μ g/kg benzo(a)pyrene.

- 0398 LOCAL VASCULAR CHANGES INDUCED BY THE CARCINOGEN, PHORBOL MYRISTATE ACETATE. Janoff, A. (New York U. Sch. Med., New York), A. Klassen and W. Troll. *Cancer Res* 30(10):2568-2571, 1970.

Vascular reactions in the ear skin of mice produced by phorbol myristate acetate, a cocarcinogen, were studied. Mice were given i.v. injections of 1 μ g of labeled bovine serum albumin, and i.v. injections of carbon suspension. One μ g of phorbol myristate acetate, produced a severe, local vascular reaction consisting of hyperemia and edema formation within

was quantitatively monitored by measuring uptake of circulating ^{125}I -labeled serum albumin. Microscopic detection of sites of endothelial injury in mice receiving i.v. carbon suspension showed the reaction to be primarily limited to venules. These microvascular changes were accompanied by mast cell degranulation in the affected tissues. Reactions developed about 1 hr after phorbol ester application, persisted through 6-8 hr, and appeared to be lessening in intensity by 24 hr. High doses (50 μg) of 7,12-dimethylbenz(a)anthracene induced similar vascular changes, although of much lower intensity and after a longer delay interval. Antagonists of histamine, serotonin, and kinins produced mild, transient suppression of the local vascular response to the phorbol ester. Hydrocortisone and salicylate were without effect on this component of the tissue reaction. A more sustained protection against the inflammation by phorbol ester was provided by local application of tosyl phenylalanine chloromethyl ketone, a protease inhibitor previously shown to suppress tumor promotion.

0399 PRODUCTION OF HEPATOMAS IN SUCKLING MICE AFTER SINGLE APPLICATION OF β -PROPIOLACTONE. (E.) Chernozemski, I. N. (Oncol. Res. Inst., Sofia, Bulgaria) and G. P. Warwick. *J Natl Cancer Inst* 45(4):709-717, 1970.

Male and female mice of various ages were given i.p. injections of 0.1 mg/g body wt β -propiolactone; suckling mice received topical applications of 0.6 mg/g body wt of the same compound. Mice receiving β -propiolactone injections on the 8th-10th day after birth developed an average of 2 hepatomas per animal in 65% of the males 16 months after treatment. In adult mice, olive oil-treated and untreated controls, the incidence of hepatomas was 9%, 4% and 6.7%, resp. Of the suckling mice which were treated with topical applications, 19.4% of the animals developed hepatomas. Treated females developed few hepatomas, though 16-20% bore malignant lymphomas (5.5% in controls). The hepatomas were trabecular or solid, and showed no metastasis to sites other than the liver, although hematopoietic embryonal cells and tumor cell embolism were observed.

0400 DETERMINATION OF THE MUTAGENIC ACTIVITY TO BACTERIOPHAGE T4 OF CARCINOGENIC AND NON-CARCINOGENIC COMPOUNDS. (E.) Corbett, T. H. (Oak Ridge Natl. Lab., Tenn.), C. Heidelberger and W. F. Dove. *Molec Pharmacol* 6(6):667-679, 1970.

The mutagenic activity of 41 carcinogens (assumed to be in the active forms) and 4 non-carcinogens and the types of mutational events produced by the active compounds were studied in bacteriophage T4. No toxicity to *Escherichia coli* BB was observed in a bacterial assay at maximal concentrations for 25 of the carcinogens so that they were presumed to be non-mutagenic. Four inorganic salts (nickel sulfate, cobalt nitrate, calcium chromate, and lead acetate) and 5 chemical carcinogens (N-hydroxy-1-naphthylamine, N-hydroxy-2-naphthylamine, N-hydroxy-2-aminofluorene, 10-formyl-1,2-benzanthracene, and DL-ethionine) were toxic but not mutagenic to intra-

cellular T4 phage. Six reactive carcinogens were mutagenic to T4 phage: β -propiolactone (producing frameshift, GC to AT, AT to GC, and the nonsense mutations amber, ochre, and UGA as well as large deletions), propane sultone (producing all except the ochre nonsense mutation), N-acetoxy-2-acetylaminofluorene and 7-fluoro-N-acetoxy-2-acetylaminofluorene (producing frameshift, AT to GC, UGA, and amber mutations as well as large deletions), glyceraldehyde (producing frameshift, AT to GC, GC to AT, and UGA mutations as well as large deletions), and nitrogen mustard (producing frameshift, GC to AT, and UGA mutations as well as large deletions).

0401 CARCINOGENICITY OF TWO N-DIAZOACETYL-DERIVATIVES OF GLYCINE IN THE NEWBORN SWISS MOUSE. (It.) Brambilla, G. (Inst. Pharmacol., U. Genoa, Italy), M. Cavanna, S. Parodi and C. E. Caraceni. *Boll Soc Ital Biol Sper* 46(5):227-230, 1970.

The incidence of lung adenomas and leukemias induced by N-diazoacetylglutylglycinamide (DGA) and N-diazoacetylglutylglycine hydrazide (DGH) was studied in newborn randombred albino Swiss mice. Both DGA and DGH were administered i.p. in doses of 180, 300 and 500 mg/kg daily for 4 consecutive days to 48-72 hr-old baby mice. The animals were weaned and sex-segregated at 30 days-of-age. The mortality within this period for the experimental animals was 15 and 8 (180 mg/kg), 15 and 9 (300 mg/kg) and 66 and 50% (500 mg/kg) for DGA and DGH, resp., and 6% for the control group. The surviving animals were sacrificed at 180-200 days-of-age. The incidence of lung adenoma was 100% in all treated groups with increasing average numbers of neoplastic nodules per lung with the increasing treatment doses; no differences between the effects of the 2 compounds were noticed. The incidence of lung tumors in the control group was 4% at 6 months-of-age. Development of leukemia was dose-dependent for both compounds: DGA seemed to be more active, producing leukemia in 10%, 43% and 71% of the animals treated with 180, 300 and 500 mg/kg, resp., than DGH which produced leukemia in 5%, 16% and 71% of the animals at the above doses, resp. A marked enlargement of the thymus, spleen and lymph nodes and leukemic infiltrations of the liver and kidney were noticed in most of the leukemic animals. No sex differences were observed in the susceptibility towards the 2 compounds. The mechanism of carcinogenesis was attributed to the alkylating action of these compounds, possibly associated with their known immunosuppressive effects, particularly in the case of N-diazoacetylglutylglycinamide.

0402 CARCINOGENICITY OF STERIGMATOCYSTIN. (E.) Purchase, I. F. H. (South African Med. Res. Council, Pretoria) and J. J. Van Der Watt. *Food Cosmet Toxic* 8(3):289-295, 1970.

Weanling rats of both sexes were fed (via gavage) or in the diet the mycotoxin sterigmatocystin in doses of 0.15-2.25 mg/day for 1 yr in order to investigate the carcinogenic properties of this

agent. Eight rats which received a high dose (1.5-2.25 mg/day) of sterigmatocystin died between wk 5 and 18, while 39 out of the 50 treated rats surviving to wk 42 eventually developed hepatic carcinoma. Of these, 31 had varying degrees of fibrosis. Eight tumours of other types were seen in the liver, uterus, ovary, spleen or omentum, and acanthotic changes occurred in the stomachs of 85% of the treated rats. The lesions produced in the livers of rats exposed to sterigmatocystin are similar to those found in Bantu hepatoma and 'toxic' hepatitis. Dietary mycotoxin may be related to the high rate of liver cancer in Africa.

0403 NEOPLASTIC SEQUELAE FOLLOWING SUBCUTANEOUS IMPLANTATION OF MICE WITH RARE EARTH METALS.

(E.) Ball, R. A. (Vetr. Med. Inst., Iowa St. U., Ames), G. Van Gelder, J. W. Green, Jr. and W. O. Reece. *Proc Soc Exp Biol Med* 135(2):426-430, 1970.

Weanling mice were implanted s.c. with 200 mg pellets of gadolinium or ytterbium, and the development of tumors in these animals and in sham-operated controls was observed. Three of 60 mice treated with gadolinium and 9 of 58 mice treated with ytterbium developed sarcomas at the implantation sites. Pulmonary metastases occurred in 4 of the ytterbium-induced sarcomas. In addition, approximately 40% of the earth-metal treated animals and 50% of the control animals developed spontaneous neoplasms, most of which were bronchial adenomas. Possibly the heavy metals promote sarcomas by uncovering latent oncogenic factors; however, the mechanism associating heavy metal implantation and carcinogenesis in these experiments remains speculative.

0404 LYSOPINE AND OCTOPINE PROMOTE CROWN-GALL TUMOR GROWTH *IN VIVO*. (E.) Lippincott, J. A. (Dept. Biol. Sci., Northwestern U., Evanston, Ill.) and B. B. Lippincott. *Science* 170(3954):176-177, 1970.

Primary leaves of bean plants were inoculated with cells of a strain of the tumorigenic *Agrobacterium tumefaciens* and subsequently treated with varying (1-20 µg/leaf) amounts of lysopine (N-α-(1-carboxy-ethyl)-L-lysine) or octopine (N-α-(1-carboxy-ethyl)-L-arginine) to investigate the ability of these compounds to promote the growth of crown-gall tumors. A detectable response was observed when 1 µg/leaf of these compounds was added, and the mean volume of the tumors was increased 2-3-fold when greater amounts were applied. The specificity of the response and the unique association of these compounds with the tumors suggest that endogenous lysopine and octopine contribute to the growth characteristics of these tumors. However, lysopine and octopine are not tumorigenic *per se*, and the identity of the substances which initiate crown-gall tumors is unknown.

0405 CHANGES IN THE NUMBER OF BONE MARROW CELLS AFTER A SINGLE INJECTION OF METHIONINE SULFOXIMINE AS COMPARED WITH THE EFFECT OF WHOLE BODY IRRADIATION WITH X-RAYS IN MICE. (E.) Zak, (Med. Fac. Charles U., Prague, Czechoslovakia) and J. Kolousek. *Neoplasma* 17(4):339-343, 1970.

Male rats were administered either 400 mg i.p. injections of DL-methionine sulfoximine or 600 of whole-body X-irradiation to test the effect of these treatments on the number of bone marrow cells in the femoral bones. Both methionine sulfoximine and X-irradiation produced a cyclical decrease in the number of bone marrow cells, with the former treatment producing a maximum decrease of 47% in bone marrow cells after 14 days as compared with controls, and the latter treatment producing a maximal decrease of 95% in bone marrow cells after 5 days. Partial regeneration by the 28th day after treatment increased the number of bone marrow cells to 70% and 50% of controls for methionine sulfoximine and X-irradiation, resp. The inhibition of bone marrow cell production by methionine sulfoximine may be due either to metabolic changes or to changes in the neurosecretory centers of the hypothalamus induced by this agent.

0406 BINDING OF RADIOACTIVE N-HYDROXY-ACETYLAMINOFLUORENE TO SYNTHETIC POLYRIBONUCLEOTIDES. (E.) Marroquin, F. (Mead Johnson Ctr., Evansville, Ind.) and N. Coyote. *Chem Bio Interact* 2(2):151-153, 1970.

The binding of 9-¹⁴C-N-hydroxyacetylaminofluorene to synthetic polyribonucleotides was studied. The labeled carcinogen was incubated with 25 mg of soluble rat liver fraction and copolymer of guanylylidylic acid (G:U). The *in vitro* system was able to bind the radioactive carcinogen to the copolymer and the binding reaction did not occur when the preparation was boiled. As the concentration of the carcinogen in the incubation mixture was increased, the binding to copolymer G:U increased. Binding rates measuring 555 and 1280 cpm/20 µm absorbance at 260 nm for carcinogen concentrations of 0.025 and 0.200 µmoles, resp. In a comparative study copolymer G:U was able to bind 42% more N-hydroxyacetylaminofluorene than copolymer G and 12-fold more than polymers of inosinic, adenylylidylic or uridylic acids.

0407 FURTHER EVIDENCE FOR TWO TYPES OF ADENYLIC ACID IN N-HYDROXY-2-FLUORENYLACETAMIDE WITH RAT-LIVER PROTEINS. (E.) Barry, E. J. (VA Hospital, Minneapolis, Minn.) and H. R. Gutmann. *Chem Bio Interact* 2(2):158-159, 1970.

The integrity of the amide linkage of protein products from the liver of rats given a single dose of N-hydroxy-2-fluorenylacetamide (N-OH-FAA, 1 mg, i.p.) throughout the isolation procedure was tested using N-OH-(1-¹⁴C)FAA. Half of the homogenized rat liver (taken 12 hr after injection) was immediately heated in boiling water for 15 min.

homogenate A) while the other half was maintained at 4°C for 4-5 hr (to simulate the isolation conditions) before boiling (homogenate B). The labeled acetic acid was recovered by the addition of sodium acetate (0.40 g) and monosodium phosphate monohydrate (1.4 g) to the homogenates, titration to pH 7.0, and steam distillation (control experiments indicated that hydrolysis of the N-acetyl group was very low under these conditions), and the titrable acidity of each distillate accounted for 24-28% of the carrier. The amount of radioactive acetic acid in homogenate A was 3.4% and in homogenate B was 6%, indicating that the amide linkage was stable during the isolation of the adducts and that the protein and nucleic acid adducts that did not retain the acetyl group observed after the administration of N-OH-FAA were not artifacts of the isolation procedure.

08 EFFECT OF ACETAMIDOFLUORENE AND ACTIVATED DERIVATIVES ON "MACROMOLECULAR SYNTHESIS" IN SINGLE CELL CULTURES. (E.) Süß, R. (German Cancer Res. Ctr., Heidelberg), V. Kinzel, M. Volm, K. Süß and J. Scribner. *Z Krebsforsch* 74(4):338-343, 1970.

Hamster embryo cells were incubated with acetoxy-, hydroxy-, or acetamidofluorene in final concentrations of 10^{-4} - 10^{-5} molar, and radioactive thymidine, uridine or leucine were added simultaneously to the cultures; the aim was to investigate effects of acetamidofluorene and its activated derivatives on macromolecular synthesis in the cell cultures as measured by the incorporation of the radioactive precursors. Precursor incorporation was reduced by 1-3 test compounds. Thymidine incorporation was reduced to 25, 25, and 5% of control values, respectively, for acetamidofluorene, N-hydroxyacetamidofluorene and acetoxyacetamidofluorene; leucine incorporation was reduced to 90, 85 and 5% of control values, respectively, by these compounds. Uridine incorporation was reduced to 80, 60, and 30% of control values, respectively. These findings correspond to the observed carcinogenic effects of the 3 compounds, of which acetoxyacetamidofluorene is the most active. As measured by precursor incorporation, DNA and RNA synthesis were more affected by the 3 test compounds than protein synthesis. Cells of the protozoan *Trichomonas pyriformis*, which were treated as were the hamster cells, showed the most significant RNA and DNA inhibition values for acetamidofluorene; in these cells, protein synthesis was virtually unaffected by any of the test compounds.

09 CHRONIC TOXICITY OF AZATHIOPRINE AND THE EFFECT OF THIS IMMUNOSUPPRESSANT ON LIVER TUMOR INDUCTION BY THE CARCINOGEN N-HYDROXY-N-2-FLUORENYLACETAMIDE. (E.) Frankel, H. H. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), S. Yamamoto, E. K. Weisburger and J. H. Weisburger. *Toxic Appl Pharmacol* 17(2):462-480, 1970.

The toxicity of chronic feeding of azathioprine and its effects on N-hydroxy-N-2-fluorenylacetamide (N-OH-FAA)-induced liver tumors were studied in male

and female Fischer F344 strain rats. Compared to control rats fed Wayne Laboratory Meal, the body weights dropped slightly for rats fed azathioprine (150 ppm), markedly for those fed N-OH-FAA (160 ppm), and were lowest for those fed a combination of both. In male rats azathioprine alone produced a normal hepatic structure with scattered enlarged parenchymal cells with watery cytoplasm; N-OH-FAA alone produced mildly nodulated liver surfaces and 9 out of 12 rats had well-differentiated hepatocellular carcinomas. The combination produced carcinomas which were difficult to differentiate in the multinodular livers (microscopically a marked increase of collagenous tissue was seen surrounding various types of parenchymal cell carcinomas). In female rats N-OH-FAA alone caused only minimal periportal fibrosis, but the combination produced a severe fibrotic reaction. The mixture of carcinogen and immunosuppressant appears to increase the toxic reaction to the liver but has no effect on the carcinogenic reaction.

0410 BINDING OF POLYCYCLIC AROMATIC HYDROCARBONS TO POLYADENYLIC ACID. (E.)

Craig, A. M. (Dept. Biochem, Biophys, Oregon St. U., Corvallis) and I. Isenberg. *Proc Nat Acad Sci* 67(3):1337-1344, 1970.

The hypothesis that some polycyclic hydrocarbons cannot bind to polyadenylic acid because their size prevents them from intercalating with the helical strands of the polyadenylic acid molecule was tested by model-building and actual binding experiments. Model building suggested that those hydrocarbons which do bind to the double-stranded, acid form of polyadenylic acid satisfy a size criterion allowing them to intercalate with the polyadenylic acid helix, thus being well protected from contact with the aqueous medium; hydrocarbons that are too large to be so protected were found not to bind. A size criterion for hydrocarbon binding to DNA was also tested. Binding experiments confirmed the size-criterion hypothesis; hydrocarbons which were predicted not to bind with polyadenylic acid, including 1,2,3,4-dibenzanthracene, pentacene, 9-phenylanthracene and 1,2,5,6-dibenzpyrene failed to bind. DNA binding hypotheses were also confirmed; 1,2,5,6-dibenzanthracene and tetracene failed to bind to DNA, and 1,2,3,4-dibenzanthracene did bind to DNA but not to polyadenylic acid. The findings appear to support the hypothesis that binding of polycyclic hydrocarbons to polyadenylic acid and to DNA is effected by intercalation, and that hydrophobic interactions are dominant in the binding process.

0411 TWO NEW TYPES OF SARCOMA INDUCING HETEROCYCLIC COMPOUNDS: BENZOCARBOLINES AND THIENOPYRIDOCARBAZOLES. (Fr.) Lacassagne, A. (Inst. Radium, Paris, France), N. P. Buu-Hoi, F. Zajdela, O. Perin-Roussel, P. Jacquignon, F. Perin and J. P. Hoeffinger. *C R Acad Sci* 271(16):1474-1479, 1970.

The oncogenicity of 15 newly synthesized heteropolycyclic compounds, 9 of which had only nitrogen

and 6 of which had both nitrogen and sulfur heteroatoms, was tested on C57BL mice. Each compound (0.6 mg) was injected s.c. 3 times at monthly intervals. Animals were sacrificed at the occurrence of the first tumor or day 553 of the experiment, and their principal organs including the tissue at the injection site were examined histologically. Two compounds which were oncogenic were 8,9-benzog-carboline, which induced sarcoma in 2 females after 301 and 346 days of latency), and 12H-pyrido[2,3-a]thieno[2,3-i]carbazole, which induced sarcomas in 3 out of 21 animals (14 males, 7 females) after 212 and 412 days of latency in the males and 276 days of latency in the female. No spontaneous tumor occurred in 4000 control animals over 500 days old. The first compound was structurally related to reserpine and constitutes the first alkaloid-like compound with oncogenic properties. The second compound was isosteric to 13H-benzo[*i*]pyrido[3,2-a]carbazole which is a strong carcinogen; apparently, substitution of benzene by a thiophene ring decreased considerably its oncogenic properties. The negative response to the other tested compounds seems to emphasize the importance of the position of the nitrogen within the pyridine ring in terms of carcinogenicity. Apparently, any increase in molecular weight of the heteropolycyclic skeleton (introduction of an additional benzene ring or methyl group or substitution of a benzene by a thiophene ring) leads to a decrease or removal of oncogenicity.

- 0412 THE GENETIC ACTION OF AROMATIC AMINES AND THEIR DERIVATIVES: INDUCTION OF MITOTIC CONVERSIONS IN THE YEAST *SACCHAROMYCES CEREVISIAE*. (Ger.) Marquardt, H. (Forest Botanical Inst. U. Freiburg, Germany), F. K. Zimmermann, H. Dannenberg, H. G. Neumann, A. Bodenberger and M. Metzler. *Z Krebsforsch* 74(4):412-433, 1970.

An investigation aimed at the characterization of the concept "genetic activity of a substance" was conducted to provide experimental data contributing to the disputed relationship between the action of a substance and its genetic activity. Derivatives of 2-aminofluorene, 4-amino-trans-stilbene and *p*-toluidine as well as 4-dimethylaminodibenzyl, *p*-nitroso- and *p*-nitrotoluene were tested for genetic activity (induction of mitotic gene conversion) in cells of yeast *Saccharomyces cerevisiae* (changes in single or a few nucleotide bases within one gene locus). N-Acetoxyacetylaminofluorene and N-acetoxyacetyl-amino-trans-stilbene were genetically strongly active as potentially ultimate carcinogens. With increasing sensitivity of the conversion system the proximal carcinogen N-hydroxyacetyl-amino-trans-stilbene still induced mitotic gene conversion, but the N-hydroxy-2-acetylaminofluorene was no longer active. The non-carcinogen and precarcinogen compounds were genetically inactive. The yeast cell was not able to N-hydroxylate the precarcinogens, acetylaminofluorene and acetyl-amino-trans-stilbene; among the toluidine derivatives only N-acetoxyacetyl-*p*-toluidide, acetyl-*p*-toluidine and its oxidation product *p*-nitrosotoluene were active. Besides the oxidation of the amino nitrogen the aromatic

nucleus also appears to be a controlling factor in genetic activity. Correlations between genetic activity and carcinogenicity were discussed in based on molecular mechanisms affecting base within gene loci.

- 0413 THE EFFECT OF CERTAIN MONO-FUNCTIONAL METHANESULPHONOXY-ALKANES ON HAEMOPOLYMER FORMING UNITS IN THE RAT. (E.) Dunn, R. (Roy. Cancer Hosp., London, England) and I. Elson. *Rev Europ Etud Clin Biol* 15(7):771-774, 1970.

The effects of methyl (MMS, 50 mg/kg, i.p.), ethyl (EMS, 175 mg/kg, i.p.), and isopropyl (IPMS, 500 mg/kg, i.p.) methanesulfonates on the number of hemopoietic colony forming units/femur (CFU/femur) and on peripheral blood neutrophil-lymphocyte ratio (N/L) were studied in female Wilkie hooded rats. The control value of CFU/femur (1400) was significantly increased by MMS (1750) and EMS (1600) and significantly decreased by IPMS (600) 48 hr after administration. When measured 24 hr after administration MMS significantly increased the CFU/femur (2050) from the control value (1400) but the increase was blocked by the simultaneous administration of (1 mg/kg, i.p.) of vinblastine sulfate (no significant effect when given alone). MMS, EMS, and IPMS depressed peripheral neutrophil-lymphocyte ratio (N/L of 10, 4.7, and 1.0, resp.).

- 0414 LUNG TUMORS INDUCED BY SMALL AMOUNTS OF HYDRAZINE SULFATE IN GONADECTOMIZED BALB/c/Se MICE. (It.) Biancifiori, C. (Dept. Cancer, U. Perugia, Italy). *Lavori Anat. Pat. Perugia* 30(2):113-119, 1970.

The effect of gonadectomy on hydrazine sulfate carcinogenesis was studied on BALB/c/Cb/Se mice grouped as follows: (A) control group of unoperated virgin animals (25 males and 25 females); (B) gonadectomized untreated animals (22 males and 22 females); (C) gonadectomized mice administered 0.56 mg of hydrazine sulfate daily or a total of 0.56 mg p.o. (24 males and 26 females); (D) gonadectomized mice treated with 0.56 mg of hydrazine sulfate (total of 84 mg), 0.28 mg (total of 42 mg) or 0.14 mg daily (total of 21 mg) consisting of 25 males and 24 females, 27 males and 21 females, and 28 males and 26 females, resp. Gonadectomy was performed at 6 wk of age and treatment started at 8 wk of age. Single spontaneous pulmonary tumors occurred in 24% of the male and 4% of the female of group A and in 9% of the male and 26% of the female mice from group B, resp. These animals died at 92-100 wk of age. Multiple (2-4) lung tumors occurred in 19 of 24 males (79%) and 19 of 24 females (79%) which died at 67-69 wk of age in group C. The incidence of lung tumors in group D was 75% after 74-76 wk, 63% and 81% after 77-79 wk and 54% and 57% after 76-80 wk, resp., in males and females according to the above described dosages.

- 15 LUNG AND LIVER TUMORS INDUCED BY SMALL AMOUNTS OF HYDRAZINE SULFATE IN BALB/c/Cb/ MICE. (It.) Biancifiiori, C. (Dept. Res. Cancer, Perugia, Italy). *Lav. Anat. Pat. Perugia*, 30(2): 99, 1970.

order to test the safety of the therapeutic use isoniazide in tuberculous patients, its chief metabolite, hydrazine sulfate, was administered to LB/C/Cb/Se mice, starting at age 8 wk. The incidence of spontaneous tumors (adenomas or/and carcinomas) in the nontreated group (25 males and 25 females) was 24 and 4%, resp. Multiple lung tumors (4/animal) developed in 90% of both males and females given 1.13 mg of hydrazine sulfate p.o. daily for a total of 170 mg each after a latency period of 59 and 64 wk, resp; no liver tumors occurred. In animals treated with 0.56, 0.28 and 0.14 mg daily (total dose-84, 42 and 21 mg, resp.), multiple tumors developed in 65% and 76%, 62% and 54%, and 54% and 32%, in males and females, resp. after a 72-78 wk latency period. Of animals subjected to short-term treatment (1.13 mg daily for 4 wk) 85% of the males and 75% of the females developed lung tumors after 66-68 wk latency period. Hepatocarcinomas developed in 7% of the males and 10% of the females given 0.56 mg hydrazine sulfate daily and in 2 males given 0.28 mg of the compound daily after a latency period of 80 wk; this low incidence was probably due to the long period of latency. These variations in the latency period may indicate that a higher daily intake of the compound for a shorter period has a higher carcinogenic potency than a lower daily intake for a longer period. The occurrence of lung and liver tumors following the administration to mice of hydrazine sulfate in doses corresponding to therapeutic doses of isoniazide administered to man, requires re-evaluation of the role of this drug in human pathology.

- 16 EPIDERMOID CYSTS IN THE THYROID GLANDS OF MALE RATS TREATED NEONATALLY WITH OESTROGEN. (J.) Arai, Y. (Juntendo U. Sch. Med., Tokyo, Japan), Maeda and S. Masuda. *Acta Endocr* 65(1):170-174, 1970.

The incidence of epidermoid cysts in the thyroid gland was determined in intact and castrated (on the day of birth) male rats given estradiol benzoate for 30 successive days from birth (1 µg daily during the first trimester, 2 µg daily during the second, and 1 µg daily during the third, s.c.). The incidence of epidermoid cysts in castrated rats receiving estradiol was 90% but dropped to 30% in intact animals receiving estradiol. No cysts were observed in intact animals given estradiol from days 31-60 after birth or in intact or castrated rats given sesame oil during the first 30 days of life.

- 17 PRODUCTION OF LEUKEMIA AND STOMACH NEOPLASMS IN SWISS, RF, BALB/c AND C3H FEMALE MICE BY FEEDING N-[4-(5-NITRO-2-FURYL)-2-THIAZOLYL]-ACETAMIDE. (E.) Cohen, S. M. (U. Wisconsin Med. Sch., Madison), E. Ertürk and G. T. Bryan. *Cancer Res* 30(9):2320-2325, 1970.

The survival rate, latent period, and incidence of lymphocytic leukemia and the incidence of stomach neoplasms were determined in Swiss, RF, BALB/c, and C3H female mice fed N-[4-(5-nitro-2-furyl)-2-thiazolyl] acetamide (NFTA). Only 16 Swiss mice fed NFTA (490 mg/mouse/13 wk) in an initial test survived and in gross and microscopic examination 15 had generalized lymphocytic leukemia and 3 had forestomach squamous cell tumors while none of the 51 control mice (surviving 14 to 49 wk) developed leukemia or any other tumors. In a 14 wk dosage study on Swiss mice, a 12 wk latent period for the leukemia was observed at 0.1 and 0.05% dietary levels of NFTA with incidences of 8/9 and 9/13, resp., and an 18 wk latent period was observed at 0.025 and 0.01% dietary levels with incidences of 8/16 and 7/14, resp. Stomach tumors were found in 12/52 mice with 6 of these incidences occurring in the highest dosage range (0.1%). After 14 wk on a 0.1% NFTA diet, leukemia was widespread in RF (12/16), BALB/c (21/29), C3H (12/24), and Swiss (22/22) strains of mice while only 3 controls (all of the RF strain) developed leukemia, and 13 mice fed NFTA displayed stomach tumors while none of the controls were afflicted.

- 0418 CYTOGENIC EFFECT OF CYCLAMATE ON HUMAN PERIPHERAL LYMPHOCYTES *IN VIVO*. (Ger.) Bau-chinger, M. (Radiobiol Inst. U. Munich, Germany), E. Schmid, M. Pieper and N. Zöllner. *Deutsch Med Wschr* 95(44):2220-2223, 1970.

The side effects of the cyclamate sweeteners (sodium or potassium salts of cyclohexylsulfamic acid) were investigated from the point of view of cytogenetic action. A chromosome analysis of peripheral lymphocytes was carried out on: a cyclamate group (3 women, 8 men) who had been placed on a cyclamate regimen due to liver or kidney disease; a control group I (3 women, 7 men) with similar diseases to those of the cyclamate group but on a regimen of fructose; and a control group II (14 women, 38 men) of healthy subjects. Both in the cyclamate group and in control group I, 48-hr cultures were obtained with an analysis of 100 cells; in the control group II 48- and 68-hr cultures were obtained. In the cyclamate group, a mean number of chromosomal aberrations was 3.3% of all evaluated cells, with a mean number of breaks/cell of 0.045, which was about 2 times higher than either control group. The chromosome aberration in the patients with liver disease was not due to a virus infection. However, these changes in the lymphocytes may not be a specific consequence of cyclamate.

- 0419 THE METABOLISM OF CYCLAMATES IN RATS. (E.) Wallace, W. C. (Food Drug Admin., Dept. Hlth. Educ. Welfare, Washington, D.C.), E. J. Lethco and E. A. Brouwer. *Pharmacol Exp Ther* 175(2):325-330, 1970.

Weanling rats of both sexes were fed cyclamates in their diet (0.4, 2.0, or 10%) for a year or more, after which 63 of them were given a p.o. intubation of ¹⁴C-cyclamate (2 µC or 2.2 mg). Essentially all of the administered dose was accounted for in the excreta after 3 days, with 35% appearing in the

urine. The cyclamate was converted to cyclohexylamine in 83% of the rats; amounts ranged from less than 0.1-38%. Small quantities of cyclohexylamine were also found in the feces. No metabolite other than cyclohexylamine was detectable. Although no attempt was made to determine at what stage during the feeding period the conversion of cyclamate to cyclohexylamine took place, prolonged or chronic feeding seemed to potentiate this conversion process. No significant amounts of excreted cyclamates were found in the bile.

- 0420 REPORT ON CYCLAMATES BY THE COMMITTEE SET UP BY THE ISRAEL MINISTRY OF HEALTH. (E.) Berenblum, I. (Weizmann Inst. Sci., Rehovot, Israel). *Israel J Med Sci* 6(4):576-579, 1970.

Artificial sweetening agents, including saccharin and cyclamates, are consumed in Israel primarily in the form of tablets, "low calorie" syrups, and sugarless soft drinks, but their use is not as widespread as it has been in the United States. Studies of the carcinogenic properties of cyclamates in laboratory animals have shown that doses of cyclamates corresponding to a consumption of 3000 tablets/day for humans (2.5 g/kg body wt/day) produced tumors of the urinary bladder in rats; in addition, calcium cyclamate and cyclohexylamine have produced teratogenic effects when injected into chick embryos. Carcinogenic effects have not been demonstrated for cyclamates in man, and the doses which produce tumors in laboratory animals are 50 times the maximum conceivable dose that a man might take. Nevertheless, Israeli authorities have recommended the restriction of the use of cyclamate concentrates and syrups (but not of cyclamate tablets), and they have discouraged the use of any cyclamate-containing product during pregnancy.

- 0421 TUMORIGENICITY OF ALDRIN, DIELDRIN, AND ENDRIN IN THE ALBINO RAT. (E.) Deichmann, W. B. (U. Miami Sch. Med., Fla.), W. E. MacDonald, E. Blum, M. Bevilacqua, J. Radomski, M. Keplinger and M. Balkus. *Industr Med Surg* 39(10):426-434, 1970.

The pesticides aldrin, dieldrin and endrin were fed to weanling rats for the duration of their lives in amounts ranging from 20-50 ppm of aldrin and dieldrin to 2-12 ppm of endrin. The toxic and carcinogenic effects of the agents were observed. Signs of acute toxicity (tremors and convulsions) were noted in a few animals of all experimental groups and were dose-related. The mean life span of females fed the highest levels of aldrin and dieldrin was shortened from a mean of 19.5 months for controls to 13.0 months for females fed aldrin 50 ppm, and 16.6 months for those fed dieldrin 50 ppm. Benign and malignant tumors were observed in 23 tissues or organs in 257 of 793 experimental and in 79 of 163 control rats examined histologically; the highest number of tumors in all groups occurred in mammary and lymphatic tissues. When compared with the controls, male and female rats fed aldrin 20, 30 and 50 ppm, and dieldrin 20, 30 and 50 ppm showed a decrease in the incidence of all tumors

and the decrease was dose-related, being lower in the rats fed the highest doses. No difference was seen in tumor incidence in control rats and experimental rats fed endrin 2, 6 and 12 ppm. The reduction in overall tumor incidence with the pesticides may be due to a disturbance of the normal metabolism of steroid hormones brought about by pesticides' stimulation of hepatic microsomal enzyme activity.

- 0422 PHARMACO-BIOCHEMICAL STUDIES ON CYTOTOXIC POLYOL DERIVATIVES: II. THE EFFECT OF BIOLOGICAL ALKYLATING AGENTS ON THE THERMAL-DENATURATION PROPERTIES OF DNA. (E.) Jeney, A., Jr. (Christie Hosp., Manchester, England), I. Szabo, Valyi-Nagy, L. Institoris and J. Szabo. *Europ J Cancer* 6(9):297-302, 1970.

The effect of biological alkylating agents on the thermal-denaturation profile of DNA (followed spectrophotometrically at 260 mμ) from calf-thymus on nucleohistone was investigated. The melting temperature (T_m) of the DNA control (62.5°C) was decreased by the addition (equivalent concentrations of alkylating agents and DNA) of nitroguanine mustard (52.5°C), Degranol (53.5°C), Merophan (55.0°C), and Endoxan (56.0°C), while dimethylmyleran (63.0°C) did not alter the T_m . The hyperchromic effect of the DNA control (40.0%) was greatly affected by Degranol (38.5%) or nitroguanine mustard (33.5%), although Merophan (26.8%), Endoxan (29.4%), and dimethylmyleran (17.0%) shifted it considerably. Of the cytotoxic hexitols examined (Degranol, dibromodulcitol, dimesylmannitol, dibromomannitol, and dichloromannitol) only Degranol lowered the T_m and none of the derivatives altered the hyperchromic effect. Histone alone raised the T_m of DNA by 10°C, pretreatment with dibromomannitol before histone raised it only slightly and pretreatment with dibromodulcitol or dimethylmyleran before histone completely blocked the increase.

- 0423 INDUCTION OF THYMIC LYMPHOSARCOMA AND MAMMARY ADENOCARCINOMAS IN RATS BY ADMINISTRATION OF THE ANTITUMOR AGENT, 4(5)-(3,3-DIMETHYL-1-TRIAZENO)IMIDAZOLE-5(4)-CARBOXAMIDE. (E.) Skibba, J. L. (U. Wisconsin Med. Sch., Madison, Wis.), Ertürk and G. T. Bryan. *Cancer* 26(5):1000-1004, 1970.

The carcinogenic effects of long-term treatment with the cancer chemotherapeutic agent 4(5)-(3,3-dimethyl-1-triazeno)imidazole-5(4)-carboxamide (DIC) were tested in rats. Twenty-four female weanling rats were fed DIC at a mean cumulative dose of 740 mg/kg body wt/14 wk. The first mammary tumor was palpable 10 wk after the start of feeding DIC, and by the time the experiment was terminated, all 24 rats had developed an average of 5 mammary adenocarcinomas. Lymphosarcoma was present in the thymus of all rats and in the spleen (20/24), lymph nodes (18/24), bone marrow (12/24). Ependymomas of the brain were present in 9 rats and pulmonary alveolar carcinomas in 4 rats. No tumors were found in the contralateral

24 rats. The alkylation of biopolymers, creation of a magnesium deficiency or activation of a latent oncogenic virus were discussed as possible mechanisms of DIC carcinogenesis.

24 INDUCTION OF DELAYED HYPERSENSITIVITY IN GUINEA PIGS BY AFLATOXINS, OTHER COUMARINS AND FURAZOLIUM. (E.) Chung, C. W. (Food, Drug Administration, U.S. Dept. Hlth. Educ. Welfare, Washington, D.C.), A. L. Giles, Jr. and T. R. Carson. *J Invest Dermatol* 55(6):396-403, 1970.

The induction of delayed skin hypersensitivity in guinea pigs by aflatoxins (B_1 , B_2 , G_1 , and G_2) and structurally related compounds was determined and rated according to severity of erythema (fractional response, average intensity, and average of ten times average intensity of positive responses). Animals sensitized intradermally with the lowest amount of aflatoxin B_1 (7.5 μ g) gave at least 1 positive reaction to aflatoxin B_1 challenge at all concentrations (0.10, 0.25, 0.50, and 1.00 μ g), but animals sensitized with larger amounts (30 μ g) by the 1.00 μ g challenge showed a significant sensitization. After immunized animals were challenged repeatedly (2 or more challenges) the initial difference in the degree of sensitization caused by different immunization procedures disappeared. Aflatoxins B_2 , G_1 , and G_2 (10 μ g), coumarin, 8-methoxypsoralen, and furazolium (25 μ g), and sterigmatocystin (20 μ g) were active in causing a delayed hypersensitivity. Animals strongly sensitized by repeated challenges with aflatoxin B_1 showed cross-reactivity to the other aflatoxins, sterigmatocystin, coumarin, and commercial perfumes, and isomers of furocoumarins, while lightly sensitized animals were moderately reactive to the aflatoxins B_2 and G_2 , negatively reactive to sterigmatocystin, and completely unreactive to aflatoxin G_1 . None of the immunized animals showed any circulating antibodies.

25 THE HISTOPATHOLOGICAL EFFECTS OF AFLATOXIN B_1 AND THE PALMOTOXINS B_0 AND G_0 ON THE LIVER OF THE DEVELOPING CHICK EMBRYO. (E.) Bassir, (Dept. Biochem., U. Ibadan, Nigeria) and A. A. Ekunle. *FEBS Letters* 10(3):198-201, 1970.

Chick embryos received inoculations of the palmotoxins B_0 and G_0 , and of the aflatoxin B_1 , (0.3 μ g/g) to determine the hepatic embryotoxic properties of these toxins. Light microscopic examination of the livers of the embryos prepared 21 days after toxin inoculation showed that in livers of embryos inoculated with aflatoxin B_1 lymphocytic infiltration had occurred, and there was a focal area of fatty change. In embryos inoculated with palmotoxin G_0 , there were also peripheral focal areas of fatty vacuolization; focal necroses with mononuclear cellular infiltrations were also observed. In embryos inoculated with palmotoxin B_0 , focal areas of marked periportal necrosis were observed, and severe fatty change had affected the tissue. Fatty infiltration was observed with all toxins inoculated, and the first 2 agents were

more potent inducers of fatty infiltration than the last agent, a finding which suggests that chick embryos are resistant to aflatoxin G_0 .

0426 AFLATOXINS AND LIVER INJURY IN THE RHESUS MONKEY. (E.) Deo, M. G. (All-India Inst. Med. Sci., New Delhi), Y. Dayal and V. Ramalingaswami. *J Pathol* 101(1):47-56, 1970.

The effects of aflatoxins on the livers of rhesus monkeys fed with varying doses of aflatoxins under conditions of good and poor protein nutrition were investigated. Male monkeys were fed with aflatoxin B_1 and G_1 in amounts of 1 mg/kg, 0.25 mg/kg, or 62 μ g/kg at intervals of 1 day, 2 times/wk or once a wk. Animals in the first 2 treatment groups also were divided according to whether they were given a protein-deficient diet or not. Of animals fed on aflatoxin 1 mg/kg and a protein-adequate diet, all died before the end of the third wk of the experiment, and 50% showed extensive hemorrhagic necrosis of the liver; all animals receiving 1 mg/kg which were fed a protein-poor diet also died by the 3rd wk of testing, and, of these, 33% showed liver necrosis. Monkeys fed aflatoxin 0.25 mg/kg developed large bizarre hyperchromatic liver cells and showed bile-duct proliferation; no animals in this treatment group showed hemorrhagic necrosis. By the 15-19th wk of treatment, lesions developed in the livers of both protein-adequate and protein-poor monkeys. Monkeys fed with aflatoxin at 62 μ g showed changes comparable to those observed in the 0.25 mg group, but in a milder form. Changes appeared later in this group, and did not progress significantly during the 2-yr course of the experiment. None of the monkeys developed tumors, and protein deficiency apparently did not exert any clear deleterious influence on the liver injury produced by aflatoxin.

0427 CARCINOGEN-INDUCED TRANSPLACENTAL EFFECTS IN THE RAT: HISTOLOGICAL FINDINGS AND THE KINETICS OF DNA-METABOLISM FOLLOWING THE APPLICATION OF AFLATOXIN B_1 , METHYLAZOXYMETHANOL-ACETATE, AND ETHYLNITROSOUREA. (Ger.) Goerttler, K. (German Cancer Res. Ctr., Heidelberg), H. P. Arnold and D. V. Michalk. *Z Krebsforsch* 74(4):396-411, 1970.

The effects of aflatoxin B_1 , methylazoxymethanol-acetate (MAM) and ethylnitrosourea administration to pregnant rats on DNA synthesis in maternal and fetal livers were investigated. On the 18th day after the insemination of rats, aflatoxin B_1 (1 mg/kg), methylazoxymethanolacetate (10mg/kg) or ethylnitrosourea (50 mg/kg) was injected i.p. Histological examinations of the maternal and fetal livers were made at various times and, 3 H-thymidine incorporation was measured for kinetic activity. Aflatoxin was found to damage the maternal livers but not those of the fetuses, and a 500% and a 200% increase of thymidine incorporation in maternal livers and fetuses, resp., was observed at 48 hr after its administration. MAM caused discrete alterations in the maternal liver and an initial decrease in thymidine incorporation followed by a 130% increase

at 48 hr after its administration; fetal tissues exhibited no morphological alterations and thymidine incorporation was 155% in the head and 120% in trunk tissues at 48 hr after treatment. Ethylnitrosourea caused minor alterations with few hepatocytic necroses in the maternal liver and severe alterations in the cellular layer of the fetal cerebral ventricles and in the olfactory region. A 140% increase in thymidine incorporation was found in maternal livers 24 hr after ethylnitrosourea administration, following an initial drop to 70%, and returned to normal at 48 hr after administration; the fetal head tissues exhibited a 35% decrease of thymidine incorporation at 3 hr and maintained levels of 50-70% 12-24 hr after administration and returned to normal at 48 hr. Thus maternal livers seemed to be more susceptible to aflatoxin B₁ and to MAM than the fetal tissues, while an opposite phenomenon occurred with ethylnitrosourea.

0428 INHIBITION BY AFLATOXIN B₁ OF RAT LIVER ZOXAZOLAMINE HYDROXYLASE INDUCTION. (E.)

Pong, R. S. (Dept. Nutr. Food Sci., Massachusetts Inst. Tech., Cambridge) and G. N. Wogan. *Biochem Pharmacol* 19(10):2808-2812, 1970.

The effect of aflatoxin B₁ on the induction of zoxazolamine hydroxylase activity by 3,4-benzpyrene was investigated. Rats were given a single i.p. injection of 3,4-benzpyrene (10 mg), followed immediately or 3-18 hr later by 3 mg/kg body wt of aflatoxin B₁. Livers were then homogenized and the microsomal enzyme hydroxylase was assayed. Benzpyrene injection caused a 3-fold increase in zoxazolamine hydroxylase activity within 24 hr of injection; a single dose of aflatoxin B₁ completely inhibited enzyme activity when the toxin was administered simultaneously with or 3 hr after the injection of benzpyrene. When aflatoxin B₁ was administered 6 or 12 hr after 3,4-benzpyrene, there was no significant reduction of zoxazolamine hydroxylase for 6 hr thereafter; however at succeeding time periods, a marked decline in enzyme activity was observed. Administration of the toxin at 18 hr after injection of 3,4-benzpyrene had little effect on enzyme activity. The inhibition by aflatoxin B₁ of zoxazolamine hydroxylase activity may have resulted from a suppression of synthesis of new enzyme protein, or from a suppression of activation of a microsomal hydroxylase activity.

0429 ESTABLISHMENT OF A TRANSPLANTABLE ASCITES VARIANT OF A RAT HEPATOMA INDUCED BY 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. (E.) Smith, D. F. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), E. F. Walborg, Jr. and J. P. Chang. *Cancer Res* 30(9):2306-2309, 1970.

A transplantable ascites variant, designated ascites hepatoma AS-30D, was established from a 3'-methyl-4-dimethylaminoazobenzene-induced rat hepatoma (0.06% dietary administration over 12 wk) and has been successfully maintained through 75 transplant generations as 2 sublines in male and female rats. The AS-30D tumor cells are of epithelial origin and grow primarily

in clusters (50 x 100 μ). Approximately 90% animals inoculated (10⁸ cells, i.p.) with AS-developed tumors, and the median survival time of host was 14 days.

0430 FINE STRUCTURE OF NUCLEI AS REVEALED BY ELECTRON MICROSCOPY: VII. HYPERPLASTIC NODULES IN RAT INDUCED BY 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE, 2-FLUORENYLACETAMIDE AND DL-ETHIONINE. (E.) Yasuzumi, G. (Nara Med. U., Kashihara, Japan), R. Sugihara, N. Ito, Y. Konishi and Y. Hiasa. *Exp Cell Res* 63(1):83-95, 1970.

The fine structure of the nuclei in hyperplastic nodules developing in livers of rats fed diet containing 3'-methyl-4-dimethylaminoazobenzene, 2-fluorenylacetamide (0.05%), or DL-ethionine for 3 wk was observed by electron microscopy autoradiography. The hepatocyte nuclei within hyperplastic nodules was characterized by a disappearance of the nuclear envelope's inner layer, the disappearance of condensed chromatin aggregates and enlargement of the nucleoli into oval or irregularly-shaped features. No differences in ultrastructural effects of the 3 carcinogens were seen. An electron microscopic autoradiograph indicated that the nucleoli in the hyperplastic area induced by ethionine were synthesizing not as actively as those in the non-treated hepatocyte so that transport of nucleolar product into cytoplasm was blocked, and the turnover of DNA in the hyperplastic nodule was considerably greater than in the non-nodular portions or in normal

0431 STUDIES ON CARCINOGEN-BINDING PROTEIN: I. ISOLATION AND CHARACTERIZATION OF AMINOAZO DYE-BOUND PROTEIN AFTER ADMINISTRATION OF A SINGLE LARGE DOSE OF 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE TO RATS. (E.) Sugimoto, T. (Fac. Sci., Tokyo, Japan) and H. Terayama. *Biochem Biophys Res Commun* 214(3):533-544, 1970.

Male rats received 40 mg of 3'-methyl-4-dimethylaminoazobenzene and were killed after 40 hr; a liver cell sap was prepared and subjected to heat treatment (55°C for 3 min), followed by chromatography on CM-cellulose. Protein-bound dye was located in the nonbasic protein fraction, the slightly basic protein fraction, and the more basic protein fractions (Fractions I, IV, VII and VI, resp.). Subsequent purification procedures, including differential precipitation by (NH₄)₂SO₄ or pH adjustment and finally gel filtration were used to separate several dye-binding proteins, I-a, I-b, VII-a and VII-b. The estimated molecular weights of these dye-binding proteins were 160,000-12,000-15,000, 160,000-170,000, 160,000-170,000, 40,000, resp. Proteins I-a, IV and VII-a showed specific binding of about 1 (mole dye/mole protein) whereas I-b and VII-b showed only a slight binding (0.07 mole dye/mole I-b and 0.01 mole dye/mole VII-b). The isoelectric points of I-a and VII were estimated to be approx. 5.2, 8.0 and 8.0, resp. Polar dye prepared from I-a, a major dye-binding protein under the present experimental

ons, showed mainly P2b and P1 components in addition to P2a, while that prepared from IV or V gave only P2a and P2a'. Preferential binding of Fraction IV protein was demonstrated for non-carcinogenic 2-methyl-4-dimethylaminoazobenzene.

2 THE SYNTHESIS OF MODEL COMPOUNDS FOR THE POLAR DYES DERIVED FROM LIVER OF RATS GIVEN 4-AMINO-2',3-DIMETHYL-AZOBENZENE. (E.) Matsumoto, M. (Inst. Sci. U. Tokyo, Japan) and H. Terayama. *Chem. Interact* 2(1):47-52, 1970.

Synthesis of 2 model compounds (4-(ethylmercapto-1-amino-2',3-dimethylazobenzene and 4-(cysteinyl-1-amino-2',3-dimethylazobenzene) of the carcinogen 4-amino-2',3-dimethylazobenzene (o-AT) was attempted to provide a synthetic approach to investigations of the *in vivo* nitrogen-sulphur bridge between o-AT and rat liver proteins. Presumably, the reaction product of ethyl sulfenyl chloride and o-AT was 4-(ethylmercapto-S-yl)amino-2',3-dimethylazobenzene. N-Trifluoroacetyl-S-thiocyanido-L-cystine methyl ester was obtained from the addition of N-trifluoroacetyl-L-cystine methyl ester to an aqueous solution of lead thiocyanogen and bromine, which was then mixed with o-AT before refluxing in potassium hydroxide/ethanol to produce 4-(cysteinyl-1-amino-2',3-dimethylazobenzene. Both model compounds contained secondary auxochromic amino groups (nitrous acid test), readily liberated o-AT, and exhibited UV and visible spectra similar to the o-AT polar dye formed *in vivo*. Apparently the binding of o-AT and rat liver proteins occurs directly through a nitrogen-sulphur bridge that involves the amino nitrogen of the dye and methionine sulphur.

3 p-DIMETHYLAMINO-AZOBENZENE (DAB) HEPATOCARCINOGENESIS IN RATS: INHIBITION BY TWO NAPHTHYLSISOTHIOCYANATES. (Fr.) Lacassagne, A. (Inst. Med. Paris, France), L. Hurst and M. D. Xuong. *Proc Soc Biol* 164(2):230-233, 1970.

The effect of α - and β -naphthylisothiocyanate (ANIT and BNIT) on p-dimethylaminoazobenzene (DAB) hepatocarcinogenesis was studied in Wistar rats receiving various compounds added to their usual (low protein and low riboflavin) diet. Six groups of animals were treated as follows: ANIT only (1 g/kg food, 8 rats), BNIT only (1 g/kg food, 10 rats), ANIT and DAB (0.6 g/kg food, 16 rats), BNIT and DAB (0.6 g/kg food, 16 rats), ANIT only (0.5 g/kg food, 10 rats) or ANIT and DAB (0.5 g/kg food) and DAB (0.6 g/kg food, 12 rats). All animals were autopsied between 50 and 480 days. ANIT alone or associated with DAB produced considerable enlargement of the portal vascular network and multiple ramifications of the peribiliary bile ducts, which developed earlier than in case of DAB administration. However, no lobular infiltration with malignant cells (occurring 25 days after DAB treatment, first stage) was noticed; slight granulosity of the peripheral liver was observed in 1 animal at day 41 after treatment with DAB. Later stages of progressive malignancy started to occur after 99 days of treatment. BNIT caused dilatation of the portal network with no bile duct involvement; it inhibited com-

pletely the effect of DAB in animals subjected to both BNIT and DAB; no alterations specific to hepatic oncogenesis occurred.

0434 REDUCTION OF THE NUMBER OF ANTIGENS IN RAT LIVER TISSUE IN THE PROCESS OF HEPATOCARCINOGENESIS. (Rus.) Khundanova, L. L. (USSR Minist. Publ. Hlth., Leningrad). *Vop Onkol* 16(8):52-57, 1970.

The reduction of the number of rat liver tissue antigens in the process of dimethylaminoazobenzene (10 mg in diet for 300-330 days) hepatocarcinogenesis was studied in male rats with antisera from immunized chinchilla rabbits and compared to liver antigens of animals treated with noncarcinogenic diethylaminoazobenzene (10 mg in the diet for 100 days). The loss of 2 normal liver antigens of the α_2 - and β -globulin region was noticed in the diethylaminoazobenzene-treated animals on the 4th day of the experiment; such loss occurred on the 15-30th days in some and on the 60-100th in most of the livers of carcinogen-treated animals; no loss of liver antigens was noticed on the 400th day of the experiment. Two antigens were missing from the hepatoma cells: one from the albumin or α_1 -globulin and the other from the α_2 - or β -globulin regions. The loss of similar (non-organ specific) antigens from liver proteins in both carcinogen- and analogue-treated animals indicated that this loss was due to a hepatotoxic effect exhibited by both compounds, while the absence of the α_1 -globulin antigen from the hepatomatous tissue seemed to be specific for the carcinogenic process.

0435 EXPERIMENTAL INVESTIGATIONS IN "SYNCARCINOGENESIS": VI. ADDITION OF MINIMUM DOSES OF FOUR DIFFERENT LIVER CARCINOGENS IN RATS IN LIVER CANCER DEVELOPMENT. (Ger.) Schmäh, D. (German Cancer Res. Ctr., Heidelberg). *Z Krebsforsch* 74(4):457-466, 1970.

An investigation was carried out to determine if syncarcinogenesis occurs when several carcinogens of various structures but with similar organotropy are administered in doses that are below tumor formation level when each is administered by itself. Ninety-six rats were given 4-dimethylaminoazobenzene (3mg/kg), dimethylnitrosamine (0.01 mg/kg) diethylnitrosamine (0.05 mg/kg) and nitrosomorpholine (0.2 mg/kg) daily p.o. for 580 days in subthreshold doses. The rats tolerated the carcinogens as well as 100 control animals, surviving for 760 days \pm 110 days; the weight gain in the experimental animals exceeded that of the control rats. The first hepatocellular carcinoma appeared after 520 days and of the original 96 animals, 86 were still alive at that time. Of these, 29 (34%) developed malignant liver tumors, 20 with hepatocellular carcinoma and 9 with hemangioendothelioma, particularly sarcoma of the liver. Metastases were observed in 6 of the 29 rats. No tumors developed in the control animals.

- 0436 BLASTOMOGENIC EFFECT OF POLYCYCLIC HYDROCARBONS: AGE DEPENDENCE OF THE EXPERIMENTAL ANIMALS. (Rus.) Bolonina, N. I. (P. A. Herzen Res. Inst. Oncol., Moscow, USSR). *Vop Oncol* 16(6): 73-76, 1970.

The age-dependent susceptibility to polycyclic hydrocarbons carcinogenicity was studied in August and Wistar rats and in C3HA and C57BL mice on 2-3 wk-old and 6 months-old animal groups of both sexes. Each animal received 0.5 mg of 7,12-dimethylbenz(a)anthracene (DMBA dissolved in paraffin, s.c.) or 0.125 mg of 3-methylcholanthrene (dissolved in apricot oil). Tumors developed in 40-56% of the animals of the younger animals, and in 68-87% of the older animals, after a latency period of approximately 3.8 months. The latency period in the baby mice (3.5 months) was 1 month shorter than in the adult mice (4.5 months). No interspecies differences in carcinogen susceptibility were noticed; marked differences were observed, however, within the species. The incidence of induced tumors was 56% (younger animals) and 87% (older animals) in the August rats and 40% and 68%, resp., in the Wistar rats. Tumor incidence was 42.5% in C57BL baby mice and 54.7% in C3HA baby mice with no differences in incidence in the adult mice. Myoblastic sarcomas (with a considerable degree of differentiation) were prevalent (40%) among the induced tumors of the younger animals while polymorphic cell sarcomas predominated in the older animals. The adult animals seemed to be more susceptible to polycyclic hydrocarbon carcinogenesis, possibly due to age-determined differences in the rate of carcinogen excretion.

- 0437 SUSCEPTIBILITY OF GUINEA PIGS TO CHEMICAL CARCINOGENS: 7,12-DIMETHYLBENZ(a)ANTHRACENE AND URETHAN. (E.) Toth, B. (U. Nebraska Coll. Med., Omaha) *Cancer Res* 30(10):2583-2589, 1970.

Guinea pigs (average wt of 94 g) received a single s.c. injection of 7,12-dimethylbenz(a)anthracene (DMBA) at birth (in amounts of 0.1-50 mg) or 3 i.v. injections of DMBA (3 mg every 3rd day for 3 doses) or urethan (1 mg/g body wt every 3rd day for 5 doses, s.c.) or 0.5 ml tri-*n*-caprylin (the base used for the DMBA and urethan) as control. The incidence, site, and histological type of induced tumors were observed, and the relative susceptibility of guinea pigs to tumor development following DMBA and urethan treatment was assessed. Following s.c. DMBA treatment, 33 animals developed a total of 37 s.c. tumors at the injection site, of which 16 were fibrosarcomas. In addition, malignant lymphomas, tumors of skin, lungs, uterus, ovaries, breast, etc., were also caused by the treatment. The i.v. injections of DMBA gave rise to higher incidences of tumors of the breast, lungs, uterus, ovaries, and skin than in the corresponding control groups. Five s.c. injections of urethan produced tumors of lungs and ovaries. The findings indicate that the guinea pig is at least as susceptible as the mouse to tumor induction by DMBA and urethan.

- 0438 EFFECT OF VARIOUS STEROIDS ON THE ADRENAL NECROSIS INDUCED BY 7,12-DIMETHYLBENZ(a)ANTHRACENE IN RATS. (E.) Somogyi, A. (Inst. Exp. Surg., U. Montreal, Quebec, Canada) and Kovacs. *Rev Canad Biol* 29(2):169-180, 1970.

The effects of various steroids with diverse properties on the action of 7,12-dimethylbenz(a)anthracene (DMBA) on the adrenal of the rat were determined by gross and histological observations. Spironolactone (18 mg, p.o.) completely inhibited the adrenocorticolytic effect of DMBA (40 mg, i.v.), while ethylestrenol (12.5 mg, p.o.), inhibited the effect by 50% (mortality studies indicated that spironolactone counteracted the general toxicity of DMBA). Testosterone (12.5 mg, p.o.) and corticosterone (17.5 mg, p.o.) moderately aggravated the DMBA-induced (3 mg, i.v.) adrenal necrosis (30% incidence in controls rose to 80%), and estradiol (1 mg, p.o.) and methylandrostenediol (13.2 mg, p.o.) exerted a very strong effect (100% incidence). Estradiol aggravated the DMBA-induced lesions at concentrations of 100 µg - 10 mg, while methylandrostenediol caused the aggravation only at concentrations of 5-10 mg. Hypophysectomy performed before initiation of estradiol treatment only slightly decreased the intensity of adrenal and ovarian grafts in the spleen did not affect the incidence or severity of lesions. Injections of the DMBA-metabolite 7-hydroxymethyl-12-methylbenz(a)anthracene (1.5 mg, i.v.) failed to produce adrenal necrosis, but animals which were treated with estradiol before the metabolite was administered developed severe bilateral adrenocorticolysis. Progesterone (13.6 mg), norbolethone (13.7 mg), ethylestrenol (12.5 mg), triamcinolone (17.0 mg), desoxycorticosterone (16.1 mg) neither inhibited nor aggravated DMBA-induced adrenal necrosis.

- 0439 GENETIC DELETIONS AT SPECIFIC LOCI IN POLYCYCLIC HYDROCARBONS IN RELATION TO CARCINOGENESIS. (E.) Fahmy, O. G. (Inst. Cancer Res., Roy. Cancer Hosp., London, England) and Fahmy. *Int J Cancer* 6(2):250-260, 1970.

The specific mutagenicity (classical technique outlined by Fahmy and Fahmy) of 4-dimethylbenz(a)anthracene with markedly different carcinogenic activities (7,12-dimethylbenz(a)anthracene, 7-bromomethylbenz(a)anthracene, 1,7-dimethylbenz(a)anthracene, and 3,9-dimethylbenz(a)anthracene) was tested in *Drosophila melanogaster*. All of the compounds proved inactive in the induction of sex-linked autosomal recessive (visible and lethal) point mutations; where marginal activity was observed, it could not be correlated with carcinogenesis. The highest incidence occurred in the non-carcinogenic 3,9-dimethylbenz(a)anthracene. Biochemical demonstrable DNA deletions within the nucleolar organizer region in the major heterochromatic region of the X-chromosome results in *bobbed* mutations and both the carcinogenic agents 7,12-dimethylbenz(a)anthracene and 7-bromomethyl-12-methylbenz(a)anthracene induced a high frequency of

mutations (6.6 per 1000 and 2.2 per 1000, resp.) compared to the controls (0.7 per 1000). These agents were similarly reactive on the *Minute* loci (4.0 and 6.1 per 1000, resp.) although all the compounds proved inactive on euchromatin loci of the X-chromosome. The mutagenicity of carcinogenic material appears to be specific for loci, chemical structure of the carcinogen, and the metabolic activity of the target cells.

0440 SUPPRESSION BY ERGOCORNINE AND IPRONIAZID OF CARCINOGEN-INDUCED MAMMARY TUMORS IN RATS: EFFECTS ON SERUM AND PITUITARY PROLACTIN LEVELS. (E.) Nagasawa, H. (Natl. Cancer Inst., Tokyo, Japan) and J. Meites. *Proc Soc Exp Biol Med* 35(2):469-472, 1970.

The effect of ergocornine, iproniazid phosphate, or dopamine (0.6 mg, 7.5 mg and 0.1 mg, resp., daily for 15-25 days) on tumor enlargement was studied. Female rats were given 5 mg of 7,12-dimethylbenz(a)anthracene i.v., and when the ensuing mammary tumors attained 1 cm in size, injection of the 3 drugs was initiated. Although dopamine had no appreciable effect on tumor growth, iproniazid phosphate and ergocornine injections completely suppressed tumor growth. A 2-fold increase in number of tumors developed was observed after drug injections were begun in dopamine-treated and control rats, whereas no significant change in number of tumors was observed in rats receiving either of the other 2 drugs. Rats treated with ergocornine had significantly lower serum and pituitary concentrations of prolactin (27.8 ng/ml of serum) than did animals treated with the other drugs (concentrations of 109.6 and 85.4 ng/ml serum for iproniazid and dopamine, resp.) Although the mechanism of mammary tumor growth inhibition by iproniazid is obscure, ergocornine probably acts by inhibiting the secretion of pituitary prolactin.

0441 THE EFFECT OF INCREASED NUMBERS OF CARCINOGENIC TREATMENTS ON THE INDUCTION OF CERVICO-VAGINAL AND VULVAL TUMOURS IN INTACT AND CASTRATE RATS. (E.) Glucksmann, A. (Strangeways Res. Lab., Cambridge, England), and C. P. Cherry. *Brit J Cancer* 24(2):333-351, 1970.

Induction of cervico-vaginal (epithelial and sarcomatous) and vulval tumors by 5, 10, 20 or 40 weekly local applications (swabbing the cervix, vagina and introitus) of 7,12-dimethylbenz(a)anthracene (DMBA, 1% solution in acetone) was studied in intact and castrated rats. Histologically, epithelial tumors progressed from a hyperplastic lesion with radiation to extruding or intruding papillomas and to fully developed autonomous carcinomas, but sarcomas formed rapidly and the early stages were not detected. The threshold for induction of cervical-vaginal epithelial tumors was less than 5 weekly paintings and the incidence rose to 60% for castrates and 20% for intact after 10 and 20 weekly paintings before dropping off to 10-15% for both groups after 40 paintings. Castration increased the incidence of vulval

tumors at the lower dose levels (5 and 10 weekly paintings) so that 50% of the epithelial tumors in castrates were carcinomas compared to 20% in the intact animals. The incidence of cervico-vaginal sarcomas leveled off in castrate animals (to approximately 30%) after 20 paintings but increased drastically in intact animals after 20 and 40 paintings (to 20% and 70%, resp.).

0442 THE PRODUCTION OF MAMMARY CARCINOMAS IN RATS BY 9,10-DIMETHYL-1,2-BENZANTHRACENE AND ITS RELATIONSHIP TO THE OESTROUS CYCLE. (E.) Young, S. (Imperial Cancer Res. Fund, London, England), D. M. Cowan and C. Davidson. *Brit J Cancer* 24(2):328-332, 1970.

The influence of the estrous cycle on the induction of mammary carcinoma by 7,12-dimethylbenz(a)anthracene (DMBA, 30 mg, p.o.) was investigated in Sprague-Dawley rats. The percentage of rats which developed mammary adenocarcinomas was similar in all phases of the cycle (81.4%, 76.2%, 73.5%, and 73.4%). However, the actual total number of tumors observed was significantly higher for the animals receiving DMBA during the di-estrous cycle (350 tumors in 57 rats) compared to the pro-estrous (205 in 48 animals), estrous (132 in 36 animals), and met-estrous (278 in 58 animals) cycles. The number of carcinomas produced by different groups of animals in the same phase of the estrous cycle also differed significantly, but the induction period of carcinomas was not affected by the stage of the cycle (12.5 to 13.5 weeks).

0443 A STUDY OF EARLY EPIDERMAL CARCINOGENESIS RELATED TO STAGES OF THE HAIR FOLLICLE CYCLE. (Rus.) Garibyan, D. K. H. (Armenian Inst. Roentgenol & Oncol, USSR) and S. A. Papoyan. *Zh Eksp Klin Med* 10(2):56-61, 1970.

The dynamics of early carcinogenesis was observed on white 2-3 month-old mice treated with 7,12-dimethylbenz(a)anthracene (0.5% soln in benzene, topically applied to the intercostal epidermis one time) during the growth and rest stages of the hair follicle cycle. The carcinogen was applied in the growth stage 3 days or in the rest stage 25 days after hair plucking. Temporary epidermal hyperplasia and enlargement of epithelial cell nuclei was noticed 24 hr following carcinogen application in the growth stage; this hyperplasia decreased in favor of epidermal keratinization during the subsequent days while hair follicle growth continued as in the controls. The carcinogen applied during the rest stage produced necrotic areas with hyperplastic boundaries on the epidermis and inflammation of the dermal skin layers; the sebaceous glands appeared enlarged and the follicle entered the catagen stage at the 30th day. The hair follicle cycle stages had a definite impact on the development of skin alterations during the early stages of carcinogenesis. The lower incidence of tumors produced by the carcinogen when applied during the follicle growth stage was possibly related to a lower oncogenic skin susceptibility during this stage.

- 0444 HAMSTER DEPIGMENTATION PRODUCED BY ORAL ADMINISTRATION OF 9,10-DIMETHYL-1,2-BENZ-ANTHRACENE. ROLE OF EPIPHYSECTOMY. (Fr.) Aubert, C. (Inst. Gustave-Roussy, Val-de-Marne, France) and C. Bohuon. *C R Acad Sci* 271(2):281-284, 1970.

Single doses of 7,12-dimethylbenz(a)anthracene (DMBA) in labrafil were administered p.o. to 4 hamster groups: 65 animals received 1 mg/3 g, 37 received 1 mg/4 g, 40 received 1 mg/5 g and 31 received 1 mg/8 g body wt. One group (27 animals) received benzanthrane (1 mg/3 g body wt) instead of DMBA, and the control group received only labrafil. Several animals were epiphysectomized before or after DMBA administration. Early depigmentation occurred 1 month after DMBA treatment in animals receiving high doses; these doses were larger than the amount necessary for induction of melanoma. Depigmentation persisted throughout the life of the animals, differed with sex and was not transmissible to descendants. Benzanthrane and labrafil had no depigmentation effects. Epiphysectomy performed 48 hr before or after DMBA administration had no effect on the depigmentation response, which seemed to exclude any endocrine involvement. The depigmentation response to high doses of DMBA seemed to be related to its toxicity and not to the carcinogenic effects produced by much lower doses (1 mg/20 g body wt).

- 0445 DIMETHYLBENZANTHRACENE TUMORIGENESIS AND ARYL HYDROCARBON HYDROXYLASE IN MOUSE SKIN: INHIBITION BY 7,8-BENZOFLAVONE. (E.) Gelboin, H. V. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), F. Wiebel and L. Diamond. *Science* 170(3954):169-171, 1970.

The importance of the mouse skin aryl hydrocarbon hydroxylase enzyme system in converting carcinogens (7,12-dimethylbenz(a)anthracene) to toxic forms was studied. When added to enzyme preparations (from control mice or mice in which the enzyme was previously induced with 1,2-benz(a)anthracene) in concentrations equimolar with the substrate, 7,8-benzoflavone and 5,6-benzoflavone inhibited the hydroxylase activity by 77-91%, while 1,2-benzanthracene was relatively inactive (21-27% inhibition); *in vivo* topical application of the flavones, 1,2-benz(a)anthracene, or 7,12-dimethylbenz(a)anthracene (DMBA) produced an induction of the hydroxylase system. Single small doses of DMBA (25 µg, topical application) followed by a promoting agent (croton oil) or repeated doses of DMBA (20 µg, topical application) initiated tumorigenesis, but 7,8-benzoflavone (21.2-27 µg, topical application) inhibited papilloma formation by 39-90%. 7,8-Benzoflavone is effective in inhibiting both aryl hydrocarbon hydroxylase in skin and DMBA-induced tumor, suggesting that this enzyme may be responsible for converting DMBA to the active carcinogenic form.

- 0446 THE REFRACTORINESS OF THE SKIN OF HAIRLESS MICE TO CHEMICAL CARCINOGENESIS. (E.) Giovannella, B. C. (Stehlin Found., Houston, Texas), J. Liegel and C. Heidelberger. *Cancer Res* 30(10):2590-2597, 1970.

Adult and newborn hairless and haired mice of the strain received topical treatment with 7,12-dimethylbenz(a)anthracene in amounts of 100 µg/0.1 ml distilled acetone; the aim was to investigate the difference in susceptibility of hairless and hairy mice to tumor induction by this carcinogen. After more than 10 wk, 44 hairless mice had developed only 7 papillomas, while 87 papillomas and 3 carcinomas had appeared in their 13 haired siblings, and 127 papillomas and 9 carcinomas had developed in 69 Swiss haired mice. Thus, the skin of haired mice was much more susceptible to chemical carcinogenesis than the skin of hairless mice. Injury to the skin with needles with or without promotion with croton oil did not alter these results. Newborn "haired" and "hairless" mice have equal amounts of hair during the first 2 weeks of life; when treated in the above manner during this period "hairless" mice developed 34 papillomas and 3 carcinomas, while 70 "haired" mice developed 66 papillomas and 11 carcinomas. Apparently, the hair follicle and its appendages play an important role in the process of cutaneous chemical carcinogenesis in mice.

- 0447 ON THE BIOCHEMICAL MECHANISM OF TUMOR GENESIS IN MOUSE SKIN: III. DECREASE IN TUMOR YIELDS BY POLY I/C ADMINISTERED DURING INITIATION OF SKIN BY AN INTRAGASTRIC DOSE OF 7,12-DIMETHYLBENZ(a)ANTHRACENE. (E.) Kreibich, G. (German Cancer Res. Ctr., Heidelberg, Germany), R. V. Kinzel and E. Hecker. *Z Krebsforsch* 74(4):389, 1970.

Tumor incidence and average tumor yield were determined in mice with skin tumors induced by intragastric application of 7,12-dimethylbenz(a)anthracene (10 µmoles) followed by the topical application of 12-O-tetradecanoyl-phorbol-13-acetate (TPA, 0.1 µmoles twice weekly for 24 wk; the synthetic double-stranded polyinosinic acid/polycytidylic acid (polyI/C) was administered (100 µg, i.p.) at initiation and before and during promotion. Animals given polyI/C during initiation showed a 2-week delay in the development of tumors, and the average yield was significantly reduced more than 50% compared to control animals. Animals receiving polyI/C before promotion had tumor incidence and average yields comparable to control animals, while animals receiving the polyI/C during promotion showed a slight decrease in tumor incidence (20%) with a slight increase in average tumor yield (10-20%).

- 0448 THE EFFECT OF TESTOSTERONE TREATMENT ON THE UPTAKE OF ³H-OESTRADIOL-17β BY 7,12-DIMETHYLBENZANTHRACENE-INDUCED RAT MAMMARY TUMORS. (E.) Mobbs, B. G. (Dept. Urol., Queen's U., Kingston, Ontario, Canada). *J Endocr* 48(2):293-297, 1970.

The effect of testosterone treatment on the uptake of 6,7-³H-estradiol in dimethylbenzanthracene-induced mammary tumors in rats was investigated. Female rats were given 20 mg of dimethylbenzanthracene

anthracene via gastric instillation, and when mammary adenocarcinomas had begun to develop the animals were treated with repeated s.c. injections of testosterone (0.2 or 1.0 mg) or with s.c. implants of 60 mg pellets of testosterone. After 10-39 days, rats were injected with 16.7 μ C of 6,7-³H-estradiol, with or without auxiliary testosterone injections. Testosterone implantation and injection of testosterone in amounts of 1 mg daily produced regression in 6 of 15 tumors. Pretreatment with testosterone lowered the uptake of 6,7-³H-estradiol, but the results were not statistically significant; however, it seemed clear that the uptake was lower when the amount of testosterone injected was high. Prolonged treatment with testosterone may alter the concentration of estradiol in the tumor tissue by affecting the metabolism of estradiol.

0449 THE EFFECT OF TESTOSTERONE ON CHEMICAL CARCINOGENESIS IN THE BUCCAL POUCHES OF CASTRATED AND INTACT MALE HAMSTERS. (E.) Polliack, A. (Rothschild-Hadassah U. Hosp., Jerusalem, Israel), I. Charuzy and I. S. Levij. *Path Microbiol* 35(5):348-354, 1970.

The effect of testosterone injections on carcinogenesis by 7,12-dimethylbenz(a)anthracene in castrated and intact hamsters was investigated. Twenty-four hamsters were castrated and 24 left intact, and both groups were given topical applications of DMBA on the cheek pouches (0.5% soln); test animals also received i.m. injections of 1.5 mg of testosterone propionate. After 9 and 12 wk of treatment, the number of squamous cell carcinomas in intact animals receiving both DMBA and testosterone was less than 50% that in animals receiving DMBA alone. Among castrated animals at 9 wk, the number of squamous cell carcinomas in animals treated with both DMBA and testosterone was compared to 3 in animals receiving DMBA alone; however at 12 wk, both groups had a similar incidence of the tumors. The tumor incidence in intact and castrated hamsters receiving DMBA alone was comparable throughout the experiment.

0450 EFFECT OF INSULIN AND OF ALLOXAN DIABETES ON GROWTH OF THE RAT MAMMARY CARCINOMA *IN VIVO*. (E.) Heuson, J. C. (Inst. Jules Bordet, Brussels, Belgium) and N. Legros. *Europ J Cancer* (9):349-351, 1970.

The effect of insulin and of alloxan diabetes on the growth of dimethylbenzanthracene-induced rat mammary carcinoma *in vivo* was determined. Animals receiving insulin (2.5 U/100 g, s.c.) and 10% glucose beverage exhibited rapid tumor growth over the 6 week observation period (10.2 cm²), and animals receiving either insulin or glucose exhibited tumor growth less rapid than the first group (6.1 and 2.5 cm², resp.) but significantly higher than controls (1.6 cm²). Diabetes (alloxan-induced 146 days after DMBA) caused regression of 57 tumors (90%) present at the onset of the study, and the tumors that remained unchanged or that continued to grow were found to be insulin-

independent when tested in organ culture. The growth-regulating effect of insulin appears to be a direct action of insulin on the tumors *in vivo*.

0451 9,10-DIMETHYL-1,2-BENZANTHRACENE CARCINOGENESIS IN THE HAMSTER CHEEK POUCH: INHIBITORY EFFECT OF TOPICALLY ADMINISTERED CORTISONE ACETATE. (E.) Polliack, A. (Hadassah U. Hosp., Jerusalem, Israel), I. S. Levij and J. W. Rwmushana. *Arch Path* 90(6):494-498, 1970.

Solutions of 7,12-dimethylbenz(a)anthracene (DMBA) (0.5% soln) and cortisone acetate (0.05% soln) were painted on the cheek pouches of hamsters 3 times/wk for 12 weeks; control animals were treated with DMBA or cortisone or paraffin. The average yield of carcinomas in treated cheek pouches was 0.6 for the DMBA and cortisone treatment; after treatment with DMBA only, it was 3.0. Decrease of tumor formation after cortisone was probably due to depression of DNA synthesis and mitotic activity by the hormone. Cortisone stabilizes biological membranes; its action on cell multiplication may be related to decreased membrane permeability with consequent inhibition of release of lysosomal enzymes which play a part in early stages of cell division. No epithelial changes were found in paraffin-treated animals, while slight hyperkeratosis of the pouch epithelium was occasionally noted in cortisone-treated animals.

0452 INHIBITION OF CHEMICAL CARCINOGENESIS IN THE HAMSTER CHEEK POUCH BY TOPICAL CHLORPROMAZINE. (E.) Levij, I. S. (Rothschild-Hadassah U. Hosp., Jerusalem, Israel) and A. Polliack. *Nature* 228(5276):1096-1097, 1970.

The effect on chemical carcinogenesis of the membrane-labilizing agent chlorpromazine was investigated. The carcinogen 7,12-dimethylbenz(a)anthracene was applied topically to the cheek pouches of hamsters (0.5% concentration) alone or together with chlorpromazine (1.2% concentration). Although the hamsters treated with carcinogen and chlorpromazine showed mild benign epithelial hyperplasia, the development of epithelial neoplasia was significantly suppressed in this group. Nine wk after treatment 4 of the hamsters treated with carcinogen alone had developed atypical papillomas, while none of those treated with carcinogen and chlorpromazine had developed tumors; after 12 wk 6/6 of the animals treated with carcinogen alone and 1/6 of the animals treated with carcinogen and chlorpromazine had papillomas. The inhibitory effect of chlorpromazine on chemical carcinogenesis may have been due to decreased permeability of cell membranes brought about by chlorpromazine.

0453 EXPERIMENTAL LIP CANCER IN HAMSTERS. (Rus.) Zil'fyan, V. H. (Inst. Roentgenol. and Oncol. Armenian S.S.R. Minist. Publ. Hlth., Erevan, USSR), B. S. Fichidzhyan and V. A. Kumkumadzhyan. *Vop Onkol* 16(6):66-69, 1970.

Cancer formation in the lip mucosa was studied in 33 grey Armenian hamsters, 80 white mice and 40 white rats. The inferior lip mucosa was treated topically with 7,12-dimethylbenz(a)anthracene (DMBA as a 0.08% benzene soln on alternate days for 4 months, a total of 60 applications). Most hamsters exhibited dryness and bleeding fissures of the inferior lip mucosa 20 days after the start of the treatment. Hair loss in the chin region (exposed to traces of DMBA) occurred at 2.5-3 months and the first papillomas of the inferior lip mucosa (in 23 hamsters) appeared at 3.5 months of the experiment; lip mucosal cancer developed 1 month later (in 16 of the 23 hamsters with papilloma). The hamsters with lip cancer died at 5.5 months-1 yr after the beginning of the treatment. Most of the white mice presented a thickening of the inferior lip and regional hair loss during the 2nd wk of treatment; ulcerations of the inferior lip mucosa and papillomas in the chin region appeared at 3 months of treatment; no malignancy was noticed among the 20 surviving mice at 5 months of the experiment. The 37 surviving white rats exhibited no alterations of the lip mucosa. Grey hamsters seemed to be more resistant to DMBA toxicity than mice and more appropriate for studies in experimental carcinogenesis.

0454 THE EFFECT OF TUMOUR GROWTH ON IMMUNE COMPETENCE: A STUDY OF DMBA MAMMARY CARCINOGENESIS IN THE RAT. (E.) Kearney, R. (Roy. Brisbane Hosp., Australia) and L. E. Hughes. *Brit J Cancer* 24(2):319-327, 1970.

The 7S and 19S antibody response (modified method of Nossal) to flagella (from motile *Salmonella adelaide*) was followed during the development of 7,12-dimethylbenzanthracene (DMBA)-induced (intragastric instillation of 4 weekly 10 mg doses) mammary carcinoma in Sprague-Dawley rats to determine if immune depression gives rise to tumors or if it is an effect of tumors in these animals. Both primary and secondary responses were depressed in female rats fed the carcinogen compared to controls ($p < .01$ at 16 weeks); surgical removal of the tumors in the carcinogen-fed animals did not restore the response. Both the 19S and 7S antibodies were equally reduced in the DMBA-treated group. Mamectomy performed after the feeding with carcinogen failed to prevent tumor development, correlating with the continued antibody depression observed in these animals. Male rats fed DMBA did not develop malignant tumors or exhibit the antibody depression, suggesting that the tumor development was involved in the depression of immune response.

0455 IMMUNIZATION OF RATS WITH A HETEROGENOUS COMPLEX: THE EFFECT ON THE GROWTH AND METASTASIS OF INDUCED TUMORS. (Rus.) Lomakin, M. S. (Acad. Med. Sci. USSR, Moscow) and E. V. Sokolova. *Biull Eksp Biol Med* 70(9):69-72, 1970.

Muscle sarcomas were induced in 110 Wistar rats, 6-8 months-old, by administration of 7,12-dimethylbenz(a)anthracene (DMBA, 5 mg in vaseline oil,

single dose). The major part of each tumor was surgically removed 4 months after DMBA administration, and the rats were distributed into 5 groups: 1) the experimental group (24 animals) subjected to immunization with a mixture of autologous tumor cells combined with human serum γ -globulin, diazobenzidine and Freund adjuvant (1.5 ml total mixture given twice at 12 days intervals); 2) control group I (22 animals) treated only with autologous tumor cells; 3) control group II (14 animals) treated with diazobenzidine and human serum γ -globulin; 4) control group III (25 animals) with their tumors removed and 5) control group IV (14 animals) tumor-bearing rats subjected to no treatment. All animals were sacrificed 40 days after last immunization. Recurrent tumors revealing lymphoid infiltration and cell necrosis developed in 14 rats and metastases appeared in 4 animals in the experimental group; 19 animals developed tumors and 12 had metastases in control group I; 12 rats had tumors and 8 had metastases in control group II; all animals developed tumors in control groups III and IV, and 14 and 13 rats developed metastases respectively. A single precipitin band (agar) of sera from all animals with autologous tumor tissue antigens was noticed in 62% of the experimental group, in 20% of control group I, in 15% of control group II and in 1% of control groups III and IV. Apparently, immunization with autologous tumor cells combined with exogenous protein produced an activation of humoral and cellular immunity factors which inhibited both growth and metastases of the primary and induced tumors.

0456 EFFECTS OF ANTI-LYMPHOCYTE SERUM ON THE GROWTH OF URIDINE BY LYMPH NODES DURING CARCINOGENESIS. (E.) Woods, D. A. (Imperial Cancer Research Fund., London, England) and C. M. Heath. *Nature* 228(5267):169-170, 1970.

The effect of anti-lymphocyte serum on the uptake of uridine by the lymph nodes during carcinogenesis was investigated in hamsters. The cheek pouch of 28 hamsters were painted with 0.5% dimethylbenzanthracene in mineral oil; 16 of the animals received anti-lymphocyte serum with a cytotoxic titer in excess of 256. Autoradiographic studies of tissues of hamsters which had received i.p. 10 μ Ci of 3 H-uridine showed the paracortical region of the nodes of all tissues examined to contain many pyroninophilic cells, some of which were uridine labeled. Hamsters treated with dimethylbenzanthracene and anti-lymphocyte serum for 3 wk showed the highest counts of pyroninophilic cells (mean cell counts/unit area: 3 and 5, resp.), while hamsters treated with dimethylbenzanthracene for 12 wk, and those treated with anti-lymphocyte serum and dimethylbenzanthracene for 12 wk showed the highest counts of pyroninophilic cells (mean cell counts/unit area: 24 and 10, resp.). In electron microscope autoradiographs the labeled cells resembled lymphocytes. Lymph node hypertrophy was most pronounced in animals treated with dimethylbenzanthracene. Impairment of the cell mediated immune response and blast cell activity by anti-lymphocyte serum, as evidenced by the relatively

bers of cells able to incorporate large quantities of uridine, may be related to the enhancement of pouch tumors.

0457 INDUCED-MAMMARY GLAND TUMORS IN RATS:
TESTING OF ANTITUMOR AGENTS. (Rus.)

Beskovny, A. M. (Inst. Endocr. Hormone Chem., Kharkov, USSR). *Vop Onkol* 16(8):62-66, 1970.

A model for cancer induction and treatment was developed in female Wistar rats 55-65 days-old administered 7,12-dimethylbenz(a)anthracene (10 mg in 0.5 ml olive oil, p.o. 3 times at 10-12 day intervals). Mammary gland tumors developed in 85-90% of the experimental animals after an average latency period of 36 days. Spontaneous regression of tumors occurred in 30% of the animals at the stage when their conventional volume was around 1000 mm³. Irreversible tumor growth occurred when its conventional volume became approximately 4000 mm³ (29 days after the first detection of the tumor by palpation). At this stage 80% of the tumors revealed an adenocarcinomatous structure, and testing of antitumor preparations was started on castrated and nonovariectomized animals. The response to therapeutic agents of DMBA-induced mammary gland carcinoma in rats was established as a valid model for such studies in human breast carcinoma.

0458 THE ROLE OF MICROSOMAL DRUG-METABOLIZING
ENZYMES IN THE BILIARY EXCRETION OF 3,4-
BENZPYRENE IN THE RAT. (E.) Levine, W. G. (Albert
Einstein Coll. Med., Yeshiva U., Bronx, N.Y.).
J Pharmacol Exp Ther 175(2):301-310, 1970.

The biliary excretion of the metabolites of the carcinogen 3,4-benzpyrene was investigated, with special reference to the role of microsomal drug-metabolizing enzymes in this excretory process. Male and female rats were given i.p. injections of tritiated 3,4-benzpyrene (10 mg/kg), and in some cases rats were pretreated with agents which induce microsomal drug-metabolizing enzymes such as phenobarbital, methylcholanthrene, or 3,4-benzpyrene. Pretreatment with these agents greatly enhanced the rate of biliary excretion of 3,4-benzpyrene. Pretreatment with methylcholanthrene led to the excretion in 1 hr of 32.7% of the compound, compared to 6.0% for controls. Both the rates of metabolism and of biliary excretion were enhanced to a similar extent throughout the induction period. Emetine inhibited both the metabolism and the rate of biliary excretion of 3,4-benzpyrene approximately 50%. Male rats both metabolized 3,4-benzpyrene and subsequently excreted its metabolites in the bile at rates approximately 2.5 times the respective rates in females. When 3,4-benzpyrene metabolites were injected, their biliary excretion rate greatly exceeded the rate seen when 3,4-benzpyrene itself was injected. This greater rate of excretion could not be further increased by treatment with inducing agents. The induction by methylcholanthrene of both the metabolism and the biliary excretion of 3,4-benzpyrene was partially blocked by ethionine.

Apparently, the acceleration of 3,4-benzpyrene excretion by inducing agents was attributable to the enhancement of conversion of the carcinogen to its metabolites; furthermore, conversion to metabolites seemed to be the rate-limiting step in the biliary excretion of 3,4-benzpyrene.

0459 IN VIVO DECREASE IN LIVER BENZPYRENE
HYDROXYLASE ACTIVITY AFTER CARBON MONOXIDE
INHALATION. (Fr.) Rondia, D. (Fac. Med. U. Liege,
Belgium). *C R Acad Sci* 271(6):617-619, 1970.

The effect of carbon monoxide on cytochrome P-450 associated enzyme systems (involved in detoxication mechanisms of the liver) was studied in male Wistar rats. Groups, consisting of 10 experimental and 10 control animals each, were exposed to carbon monoxide, 60 ppm for 120 hr, 100 ppm for 168 hr and 150 ppm for 48 and 120 hrs. All animals were sacrificed at the end of the exposure period, and their liver homogenates with the necessary coenzymes and 0.1 mmole of benzpyrene, were incubated at 37°C for 10 min. Benzpyrene hydroxylase activity was measured by both the determination of the nonmetabolized benzpyrene and the determination of the product, 3-hydroxybenzpyrene. Exposure to 60 ppm carbon monoxide lowered the enzyme activity by 13% and exposure to 20 ppm carbon monoxide lowered the activity by 20%. The enzyme activity appeared to increase during the first 48 hr of exposure with 150 ppm, but decreased by 25% after 120 hr of carbon monoxide inhalation. Slight anoxia seemed to modify the composition of the reticuloendothelial system of rat liver, and carbon monoxide seemed to be acting specifically on one of the liver hydroxylation electron transfer systems, where the involvement of cytochrome P-450 could not be confirmed by spectrophotometry.

0460 INHIBITORY ACTION OF CHEMICAL CARCINOGENS
ON MITOSES OF RAT LUNG CELL CULTURES. I.
3,4-BENZPYRENE. (Fr.) Guerin, M. (Inst. Res. Sci.
Cancer, Villejuif, France), I. Chouroulinkov and P.
Lazar. *C R Soc Biol* 164(2):234-238, 1970.

The antimitotic effects of 3,4-benzpyrene were studied in rat embryo lung cell cultures (Parker 199 media treated with 20% calf serum). 3,4-Benzpyrene added as a 0.1% acetone solution at a ratio of 5γ/ml culture media inhibited mitosis completely. When samples treated with 0, 0.001, 0.01, 0.1 and 1.0γ were maintained for 7 days, the mitotic index decreased correspondingly to give the following values; 7.8, 7.5, 4.4, 0.3 and 0, resp. Mitotic inhibition was attributed to a specific action of 3,4-benzpyrene on the mitotic cycle of the cell rather than to its toxic effects. Similar antimitotic effects induced by other chemical carcinogens are reviewed.

0461 SOLUBILITY OF POLYCYCLIC HYDROCARBONS IN
SERA. (Ger.) Obrikat, H. (Hyg. Inst. Hum-
boldt U., Berlin, Germany) and K. Wettig. *Arch Ge-
schwulstforsch* 35(4):326-337, 1970.

The increase in the number of cases of bronchial carcinoma is attributed to air pollution largely with carcinogenic polycyclic hydrocarbons. The elimination of these particles from the lungs is dependent upon their solubility in the body fluids. This property was investigated in the sera of calf, horse and man with pyrene and 3,4-benzpyrene. It was established that the carcinogenic benzpyrene is less soluble than the noncarcinogenic pyrene, and its solubility in human serum is significantly greater than in calf or horse sera. The blood group or Rh factor did not affect the solubility, and an increase in gamma globulin concentration decreased the solubility. Because an inflammatory process often precedes cancerous events and serum lipids are increased, benzpyrene absorption is facilitated. It is postulated that reduced ciliary action in inflammatory processes of the respiratory tract influences the elimination of particles adversely, and carcinogenesis in such instances is more likely to occur.

- 0462 EFFECT OF METHYLCHOLANTHRENE ON BIOSYNTHESIS AND METABOLISM OF BILE ACIDS. (E.) Johansson, G. (Karolinska Inst., Stockholm, Sweden). *Biochem Pharmacol* 19(10):2817-2820, 1970.

The effect of methylcholanthrene on hydroxylation reactions involved in the biosynthesis and metabolism of bile acids was investigated in male rats. Rats were given daily injections of 25 mg/kg 3-methylcholanthrene for 3 days. Hydroxylation substrates were incubated with liver homogenates from these rats, and thin-layer chromatography of extracts of incubations with the different neutral steroids and 3,4-benzpyrene was performed. The patterns of hydroxylation products were the same in control rats and in methylcholanthrene-treated rats. Total conversion of cholesterol, cholest-5-ene-3 β , 7 α -diol conversion into 7 α -hydroxycholest-4-en-3-one, and hydroxylation of 7 α -hydroxycholest-4-en-3-one were similar in treated and control animals. The rate of 7 α -hydroxylation of taurodeoxycholic acid was not affected by methylcholanthrene treatment. The 6 β -hydroxylation of taurochenodeoxycholic acid and lithocholic acid was less effective in methylcholanthrene-treated rats than in control rats, with hydroxylation rates for taurochenodeoxycholic and lithocholic acids being, resp., 2.2 and 1.8 times faster in control rats than in treated rats. In methylcholanthrene-treated rats, however, the extent of formation of hydroxylated derivatives of 3,4-benzpyrene was 6.8 times greater than in controls. Apparently, methylcholanthrene does not affect any rate-limiting component of the hydroxylations involved in the biosynthesis of bile acids.

- 0463 ENHANCED INITIATION OF RNA CHAINS IN LIVER AFTER ADMINISTRATION OF 3-METHYLCHOLANTHRENE. (E.) Bresnick, E. (Baylor Coll. Med., Houston, Tex.) *Biochem Biophys Acta* 217(1):204-206, 1970.

Chromatin prepared from liver nuclei (method of Dingman and Sporn) of 3-methylcholanthrene-treated

(20 mg/kg, i.p.) rats was incubated with RNA polymerase from *Escherichia coli* in the presence of γ -³²P-ATP to determine the effect of methylcholanthrene (MC) on the initiation of RNA chains. A 10 min the amount of ATP incorporation into RNA 1.6 times greater with MC-chromatin (8000 cpm) with control-chromatin (5000 cpm), and the incorporation required RNA polymerase, chromatin, and divalent cations. Pancreatic ribonuclease (5 μ) added to the incubation mixture at zero time inhibited both the control and experimental reaction by 80%; when the RNA product was treated with a line phosphatase the ³²P label was acid-soluble and norite-non-absorbable while treatment with creatine ribonuclease and hydrolysis left the ³²P label acid-soluble but norite-absorbable, indicating that the label was located in the phosphodiester linkage at the terminus of the RNA chain.

- 0464 INDUCTION OF DRUG METABOLISM: V. INDEPENDENT FORMATION OF CYTOCHROMES P-450 AND P₁-450 IN RATS TREATED WITH PHENOBARBITAL AND 3-METHYLCHOLANTHRENE SIMULTANEOUSLY. (E.) Bidh K. (U. Minnesota Coll. Med. Sci., Minneapolis) G. J. Mannering. *Molec Pharmacol* 6(6):697-701, 1970.

The effects of phenobarbital (40 mg/kg/day, i.p.) and 3-methylcholanthrene (20 mg/kg/day, i.p.) administered alone or in combination on the induction of cytochromes P-450 and P₁-450 were studied in Simonsen rats. 3-Methylcholanthrene caused the formation of cytochrome P₁-450, increased aniline binding, the A₄₅₅:A₄₃₀ ratio, and 3-methyl-4-methylaminoazobenzene N-demethylase activity, increased hexobarbital binding, and did not affect ethylmorphine N-demethylase activity, while phenobarbital caused the formation of cytochrome P-450 and increased all of the above measurements except the A₄₅₅:A₄₃₀ ratio. Simultaneous administration elevated the aniline and hexobarbital binding, the 3-methyl-4-methylaminoazobenzene N-demethylase activity nearly to the sums of each of these measurements when the agents were administered singly. Apparently cytochromes P-450 and P₁-450 are synthesized independently of each other since the simultaneous administration of the 2 agents results in the formation of both cytochromes.

- 0465 OXYGEN CONSUMPTION AND HISTOLOGICAL CHANGES OF MOUSE SKIN DURING THE INDUCTION OF CUTANEOUS SARCOMA WITH METHYLCHOLANTHRENE. (E.) Zador, S. (Inst. Res. Sci. Cancer, Villejuif, France) *Virchow Arch Zellpath* 6(1):72-78, 1970.

The carcinogen 3-methylcholanthrene was injected s.c. in amounts of 1 mg in olive oil in mice, the consumption of oxygen and lactic acid was measured in tissue slices from the injection site during the development of sarcomata. Oxygen consumption tended to increase slightly with time in treated and in untreated animals, an abrupt increase when sarcomas developed was seen (2.14 μ l/hr/mg before appearance of tumor and 2.58 μ l/6 hr/mg after tumor appearance). Lactic acid production

increased approximately 75% as soon as sarcomas developed. No systematic influence on hair growth was found in the carcinogen-treated animals, nor could any other qualitative alterations be demonstrated.

0466 MECHANISM OF 3-METHYLCHOLANTHRENE-INDUCED INHIBITION OF DIMETHYLNITROSAMINE DEMETHYLASE IN RAT LIVER. (E.) Venkatesan, N. (US Publ. Hlth. Service Hosp., New Orleans, La.), M. F. Argus, and J. C. Arcos. *Cancer Res* 30(10):2556-2562, 1970.

Immature male rats were given i.p. injections of 3-methylcholanthrene (30 mg/kg body wt) to investigate the time course of DMN demethylase inhibition. At 10 hr after injection of the inhibitor, DMN activity was reduced by 17.7%, inhibition rising to 37.6% at 15 hr. DMN demethylase activity in liver microsome preparations of treated rats was similar to that in untreated livers, indicating that there is no endogenous DMN demethylase inhibitor in rat livers. Kinetic studies on DMN demethylase activity showed that the enzyme in both 3-methylcholanthrene-pre-treated rats and untreated rats had similar K_m values (control K_m being $22.6 \times 10^{-5}M$, and treated K_m being $22.0 \times 10^{-5}M$). The V_{max} for treated and untreated rats were significantly different, treated and untreated rats showing values of 8.7 μ moles HCHO/mg protein/30 min, and 12.2 μ moles, resp. Phenobarbital treatment also inhibited DMN demethylase, though to a lesser extent than 3-methylcholanthrene. No sex difference was detected in DMN demethylase sensitivity to inhibition by 3-methylcholanthrene in young adult male and female rats. Furthermore, no change in DMN demethylase activity was brought about by prolonged treatment of immature female rats with 15 mg/ml of 17 α -methyltestosterone. The inhibitory effects of actinomycin D (20 μ g) or puromycin (2 mg) administered to rats on DMN demethylase inhibition by 3-methylcholanthrene were additive, suggesting that the hydrocarbon and the antibiotics do not act at the same target. 3-Methylcholanthrene appears to affect the gene which codes for DMN demethylase.

0467 VIRUS-LIKE PARTICLES IN CHEMICALLY INDUCED SARCOMAS IN HIGH- AND LOW-LEUKEMIA STRAINS OF MICE. (E.) Liebelt, R. A. (Baylor Coll. Med., Houston, Tex.), S. Suzuki, A. G. Liebelt and M. Lane. *Cancer Res* 30(9):2438-2448, 1970.

The incidence of sarcomas and virus-like particles was determined in high-leukemia strains of mice (AKR/Ki and C58/Ki) following a single injection of 3,4-benzpyrene (0.004 mg/g, s.c.) and in newborn AKR mice following 3-methylcholanthrene (0.05 ml of 0.5% in olive oil). Sarcomas developed with comparable frequency in the low-leukemia strains (21-50% incidence) after 3,4-benzpyrene, but the incidence was much lower in the high-leukemia strains (3.6% and 8%) after benzpyrene, although in the high-leukemia strain AKR the incidence was relatively high (40%) after 3-methylcholanthrene. Type C murine leukemia virus particles were found abundantly in pri-

mary and transplanted sarcomas and in normal tissue of AKR and C58 strains, less frequently in primary and transplanted sarcomas in BALB/cf, C3H/f, and C3H mice, and not at all in either sarcomas or normal tissue of Af mice. Type A virus particles were seen in sarcomas and normal tissue of AKR and C58 mice but not in any of the other strains. Cell-free extracts of Af tumor tissue caused reticular tissue, lung and liver tumors in BALB/cf, C3Hf and C57BL mice, but none of the animals developed sarcomas. Cell-free extracts of C58 virus were injected into newborn BALB/cf mice and significantly increased the incidence of lung tumors only after material from a sixth generation transplant was used and not after a first generation transplant; cell-free extracts of AKR injected into newborn BALB/cf mice showed no lung tumors or reticular tissue neoplasms in the injected mice compared to a 17-19% incidence of lung tumors and a 7-28% incidence of leukemia in controls. A complicated interaction between host genetic factors and the different viruses is suggested.

0468 SEARCH FOR COMMON ANTIGENICITIES AMONG TWENTY-FIVE SARCOMAS INDUCED BY METHYLCHOLANTHRENE. (E.) Basombrio, M. A. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.). *Cancer Res* 30(10):2458-2462, 1970.

Female mice were implanted with millipore discs containing 5% of 3-methylcholanthrene, and the ensuing tumors (pleomorphic sarcomas and rhabdomyosarcomas) were excised preparatory to challenging the established tumor immunity with various intradermal inocula of tumor cell suspensions. The aim was to investigate the possibility that antigenic specificities may be shared by 25 tested sarcomas. Two modalities of the transplantation test for antigenicity, designated as "multiple challenge" and "multiple immunization," were used. The first consisted of immunizing mice with 1 tumor and testing in them the rejection of the same and others when threshold cell doses were injected intradermally in different skin sites. Each one of the tumors was clearly rejected in mice immunized with the same tumor line, but it grew regularly in mice immunized with each one of the other tumors and in controls. There appeared to be some instances of cross-immunization in a first screening of the 90 possible tests between 10 tumors, but no such cases could be reproduced for any pair of tumors. Evidently, each of 10 tumors tested had a different antigenic type. Fifteen tumors were studied in multiple immunization experiments consisting of inducing immunity simultaneously with 4 tumors and challenging this immunity with a single, different one. No stable cross-protection was revealed in 13 out of 14 such tests. One tumor pool was selected, however, which cross-immunized against a different tumor in 3 out of 3 tests; this pool failed to protect against 4 other tumors. Totally and partially shared antigenic components among methylcholanthrene induced tumors, as evidenced by rejection of tumor cell inocula, appear to be extremely rare phenomena.

- 0469 COMPARATIVE DISTRIBUTION OF DEHYDROGENASES IN MOUSE EPIDERMOID EPITHELIOMA AND NORMAL SKIN. (Fr.) Dokov, V. K. (Lab. Anat. U. Liege, Belgium), M. A. Gerebtzoff and P. Minet. *C R Soc Biol* 164(3):675-676, 1970.

Dehydrogenase activities in a methylcholanthrene-induced epithelioma (C3H mouse skin) were studied 15 days after transplantation and compared to levels in normal mouse epidermis. The distribution of glutamate dehydrogenase in the cytoplasm of tumor cells was higher at the chromosomal level of mitotic cells (mainly in metaphasic stages) and generally higher than in normal epidermis, due to enhanced amino acid biosynthesis. Activities of succinate, glucose-6-phosphate and isocitrate dehydrogenases were highest in the cytoplasm of glandular structures. Lactate dehydrogenase activities were high in all tumor cells, and no differences between isoenzyme activities were observed. The pseudokeratinization process of epidermoid epithelioma cells was associated with high glucose-6-phosphate and isocitrate dehydrogenase levels, indicating an enhancement of the pentose phosphate shunt, the Krebs cycle and nucleoprotein synthesis. The increased levels of dehydrogenase activity in tumor cells appear to be associated with the proliferative process of the tumor cell population, with higher energy requirements, glucose degradation and protein synthesis rates than normal cells.

- 0470 SKIN TUMORS IN ACI/N RATS INDUCED BY 3-METHYLCHOLANTHRENE AND 4-DIMETHYLAMINOSTILBENE. (E.) Takayama, S. (Cancer Inst. Tokyo, Japan). *Gann* 61(4):367-371, 1970.

The effect of p.o. 4-dimethylaminostilbene on skin tumor induction by topical application of 3-methylcholanthrene was studied in ACI/N rats. Groups of male and female rats were treated in one of 4 ways; painting with 0.3% 3-methylcholanthrene in acetone (20 wk), 3-methylcholanthrene painting and 0.05% 4-dimethylaminostilbene diet (20 wk), 4-dimethylaminostilbene diet alone (20 wk), and acetone painting alone (20 wk). Skin painting with 3-methylcholanthrene produced skin tumors in 19 of 20 rats with an average latent period of 32 wk. Painting with the compound combined with dietary 4-dimethylaminostilbene produced tumors in 17 of 18 rats with an average latent period of 30 wk. Dietary 4-dimethylaminostilbene produced no skin tumors in 17 of 20 rats (the remaining 3 rats having died before the 10th wk) and no tumors were found in 28 acetone-painted rats. The skin tumors produced were usually multiple in occurrence, and trichoepitheliomas were most abundant (50%) in animals painted with 3-methylcholanthrene, while basal cell carcinomas were most common (44%) in the group treated with 3-methylcholanthrene and 4-dimethylaminostilbene.

- 0471 POSSIBLE ASSOCIATION OF EMBRYONAL ANTIGEN(S) WITH SEVERAL PRIMARY 3-METHYLCHOLANTHRENE-INDUCED MURINE SARCOMAS. (E.) Brawn, R. J. (U. Washington Med. Sch., Seattle). *Int J Cancer* 6(2):245-249, 1970.

The effects of lymph-node cells (5×10^6 cells) from multiparous pregnant BALB/c mice and from age-matched BALB/c virgin female mice on *in vitro* colony formation of several lines of primary 3-methylcholanthrene-induced murine sarcomas were compared. Lymphocytes from multiparous pregnant mice significantly inhibited the colony formation of the induced sarcoma compared to lymphocytes from virgin controls, but did not inhibit the growth of normal fibroblast tissue. Lymph-node cells from the pregnant mice mediate an immune response against embryonal sarcoma associated only with cultured MCA-induced neoplastic cells, although the observed response may be non-specific and related to the physiological differences between pregnant and virgin mice.

- 0472 ELECTRONIC STRUCTURES AND MECHANISM OF CARCINOGENICITY FOR ALKYL NITROSAMINES. (E.) Nagata, C. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan) and A. Imamura. *Gann* 61(2):169-176, 1970.

Electronic structures of a carcinogenic (methyl ethylnitrosamine) and a non-carcinogenic (diallyl nitrosamine) nitroso compound were calculated using the CNDO method (complete neglect of differential overlap), and the electronic states of the proposed metabolic pathways were compared. The most stable structure for methylethylnitrosamine was estimated by comparing the calculated total energies for possible stereo-structures; the calculated electrostatic charges for the presumed stable structures of methylethylnitrosamine and for diallylnitrosamine are compatible with the α -carbon hydroxylation subsequent heterolysis. The energy increment (energy of the products minus the total energy of reactants) calculated for each step in the assumed metabolic pathway (enzymic hydroxylation, heterolysis, and alkylation through a bimolecular nucleophilic reaction or through a monomolecular nucleophilic substitution) was lower for the non-carcinogenic agent in all the reactions except in the alkylation preceding an S_N2 mechanism (bimolecular nucleophilic reaction), indicating that this is the critical rate-limiting step in the carcinogenic action of nitrosamine compounds.

- 0473 METABOLISM OF DIMETHYLNITROSAMINE BY HUMAN LIVER SLICES *IN VITRO*. (E.) Montesano, R. (Middlesex Hosp. Med. Sch., London, England) and P. N. Magee. *Nature* 228(5267):174, 1970.

Human liver slices were incubated with ^{14}C -dimethylnitrosamine in order to investigate the metabolism of this compound by liver slices as an indicator of possible carcinogenic effects of the compound in man. The production of labeled carbon dioxide from methylation of slice nucleic acids was used to monitor dimethylnitrosamine metabolism. These results compared to those of similar experiments using rat liver slices showed that the respiration rate of the rat liver slices ($760 \mu l O_2/g$ wet wt/hr) was higher than the respiration rate of the human liver slices ($240 \mu l O_2/g$ wet wt/hr), and that rat slices produced more $^{14}CO_2$ in 100 min (5.2%) than did human slices (3.0%). Nucleic acid me-

ation rates were lower for human slices (0.13%) than for rat slices (0.19%). The results indicate that human liver can metabolize dimethylnitrosamine at a rate comparable with rat liver; the similar levels of nucleic acid methylation in the 2 species suggest that man may be as sensitive as the rat to the carcinogenic effects of this compound.

- 0474 AMINO ACID INDUCTION AND CARBOHYDRATE REPRESSION OF DIMETHYLNITROSAMINE DEMETHYLASE IN RAT LIVER. (E.) Venkatesan, N. (US Publ. Hlth. Service Hosp., New Orleans, La.), J. C. Arcos and M. F. Argus. *Cancer Res* 30(10):2563-2567, 1970.

The effect on dimethylnitrosamine (DMN) demethylase in rat liver of starvation and treatment with various agents including 3-methylcholanthrene was investigated. Male rats were starved or fed, and administered 3-methylcholanthrene (40 mg/kg), actinomycin D (20 µg), casein, glucose, or cellulose. Starvation more than doubled the demethylase activity measured in (nmole HCHO/mg protein/40 min) from 17 in fed to 37 in starved rats, resp. Treatment with 3-methylcholanthrene inhibited the enzyme to the same extent in starved animals as it did in fed animals, DMN methylase activity measuring 9 and 24 nmole HCHO/mg protein/40 min, resp., for methylcholanthrene-fed and methylcholanthrene-starved animals. Starvation did not cause significant increases in the K_m of the enzyme; however, the V_{max} was significantly elevated in starved animals (51.7% increase), indicating an increase in demethylase. The starvation-induced DMN demethylase activity was blocked when actinomycin D was administered to rats throughout the fasting period. The findings with actinomycin D indicate that the starvation-induced increase of demethylase activity was due to original protein synthesis, a hypothesis which is consistent with the observed increase in V_{max} of the enzyme. Ingestion of glucose markedly inhibited demethylase activity compared to the starved state; rats fed glucose had DMN demethylase activity of 17.4 nmole HCHO/mg protein/40 min, and starved animals had an activity of 44.6 nmole HCHO/mg protein/40 min. Casein stimulated demethylase activity to 59.7, and cellulose had no effect on the activity.

- 0475 INVESTIGATION OF RIBOSOMAL PROTEINS: III. ALTERATIONS OF THE RIBOSOMAL FERRITIN-FRACTION INDUCED BY HEPATOTROPIC CARCINOGENS. (Ger.) Meyer-Bertenrath, J. G. (St. Hosp. Hanau, Germany) and W. Domschke. *Z Naturforsch* 25(7):744-748, 1970.

To determine the effect on liver ribosomes of carcinogenic agents such as N-nitrosomorpholine (NNM), diethylnitrosamine (DENA) or thioacetamide (TAA), an investigation was carried out in rats pretreated for 60 days with a 12 mg/100 ml concentration of NNM or DENA and a 30 mg/100 ml TAA solution for 6 weeks. Determinations of the Michaelis constants of ribonuclease, with ribosome or ferritin-free subribosomal particles demonstrated that the ribosomes from the carcinogen-pretreated animals contained RNA structures with a different ferritin fraction than did the normal ribosomes, the Michaelis con-

stant being 100-fold higher for the former. The ribosomal ferritin fraction remained unchanged for at least 2 months following the removal of the carcinogenic agent. It is suggested that this test can be applied to human liver biopsies.

- 0476 TOXICITY AND ONCOGENICITY OF NITROSOMETHYLANILINE AND NITROSOMETHYLCYCLOHEXYLAMINE.

(E.) Goodall, C. M. (Natl. Cancer Res. Lab., U. Otago, New Zealand), W. Lijinsky, L. Tomatis and C. E. M. Wenyon. *Toxic Appl Pharmacol* 17(2):426-432, 1970.

From acute and chronic toxicity studies of N-nitroso-N-methylaniline (NMA) and N-nitroso-N-methylcyclohexylamine (NMC) in rats, mice and hamsters, 3-day LD₅₀ values were determined. The LD₅₀ (mg/kg) of NMA (by gavage) was 336 in male rats, 225 in female rats, and 150 in hamsters; the LD₅₀ of NMC (by gavage) was 80 in male rats, 180 in female rats, 168 in hamsters, and 57 in mice (the convulsant effect of NMC was prevented by anesthesia), and the LD₅₀ for injections of NMC (saturated solution in water, i.p.) in male rats was 28 mg/kg. Neither compound produced apparent histologic lesions of liver or other organs. Chronic studies of NMA and NMC administered by gavage (7.5 mg, 2 days/wk and 2 mg, 2 days/wk, resp.) and in drinking water (1.0, 2.0, and 4.0 mg, 5 days/wk for each compound) indicated that both NMA and NMC are potent carcinogens producing sessile papillomas and squamous carcinomas in the upper gastrointestinal tract and that both produced liver damage after prolonged treatment.

- 0477 THE TRANSPLACENTAL EFFECT OF DIMETHYLNITROSAMINE IN ORGAN CULTURES OF THE KIDNEYS. (Rus.) Sorokina, Yu. D. (Inst. Clin. and Exp. Oncol., Moscow, USSR) *Biull Eksp Biol Med* 70(8):77-81, 1970.

Dimethylnitrosamine administered to C3HA pregnant mice (0.25 mg/kg, s.c., 2 days before explantation) led to considerable changes in embryo kidney organ cultures which had been explanted at 19-21 days of pregnancy. Diffuse hyperplasia of the tubular epithelium manifested by partial or total epithelization of the explants was noticed 2 wk after explantation. After 10 days of culture maintenance papillary outgrowths (hyperplastic epithelial foci) appeared. Furthermore, the transplacental effect of the carcinogen determined a better survival of the embryo explants at the later stages of the investigation. The diffuse and focal epithelial hyperplasia possibly constitute the first stages of pretumoral transformation.

- 0478 TRANSPLACENTAL INDUCTION OF MALIGNANT TUMORS BY ORAL ADMINISTRATION OF ETHYLUREA AND NITRITE TO RATS. (Ger.) Evankovic, S. (German Cancer Res. Ctr. Heidelberg, Germany) and R. Preussman. *Naturwissenschaften* 57(9):460, 1970.

The endogenous synthesis of nitrosoamides demonstrable in transplacental carcinogenesis was illustrated in an experiment on 7 pregnant rats, by the administration of ethylurea at 100 mg/kg 13-23 days after coitus and 50 mg/kg of sodium nitrite

CHEMICAL CARCINOGENESIS

directly afterwards by stomach tube. Of the newborn animals 13/19 survived, and 10 rats died between 77-211 days. These latter showed neurogenic tumors and a leukemia, resp. The administration of either ethylurea or sodium nitrite alone did not demonstrate any tumor formation. The tumors described are typical of the transplacental action of ethylnitrosourea and demonstrate their origin in the gastrointestinal tract.

- 0479 TUMORS OF OROPHARYNX AND FACE IN NZO, NZB, AND NZY MICE TREATED WITH N-NITROSO ALI-CYCLIC IMINES. (E.) Geary, C. P. (Natl. Cancer Res. Lab., U. Otago, New Zealand), C. M. Goodall, M. Bielschowsky and W. Lijinsky. *Pathology* 2(4):261-268, 1970.

The incidence and pathology of oropharyngeal and facial tumors in NZB, NZO, and NZY/B1 mice following the administration of N-nitrosohexamethyleneimine (NHM) or N-nitrosopentamethyleneimine (NPIP) in drinking water (200 mg/l) over two 4-week periods were studied. Fourteen of the 135 mice given NHM and 3 of the 22 given NPIP developed the tumors, indicating that the oncogenic capacity of both ali-cyclic nitroso imines were similar. No significant difference in tumor incidence was noted between male and female mice (10 and 7, resp.), but a genetic influence was suggested by the 12.5% incidence in the closely related NZB and NZO/B1 strains compared to the 3.2% incidence in the unrelated NZY/B1 strain. All the tumors were squamous epithelial neoplasms (except for 1 histiocytic malignant lymphoma) and were invasive carcinomata (frequently infiltrating adjacent connective tissue and muscle fascial planes) showing varying degrees of differentiation.

- 0480 CYTOPHOTOMETRY OF THE TRACHEAL MUCOSA AND OF THE DENA-INDUCED PAPILLOMATA OF THE SYRIAN GOLDEN HAMSTER: QUANTITATIVE STUDIES OF DE-DIFFERENTIATION. (Ger.) Tasca, C. (German Cancer Res. Ctr., Heidelberg), D. Haag and K. Goerttler. *Z Krebsforsch* 74(4):355-367, 1970.

Cytophotometric criteria (based on 3700 nuclei) of differences between normal and neoplastic cells are described. The tissues used in the comparative study were taken from pregnant golden hamsters in whom tracheal papillomata were induced by means of DENA (50 mg/kg diethylnitrosoamine, s.c.) 8 days following insemination. The mothers and progeny were sacrificed 6 months following the treatment and the trachea was prepared for cytological examination. With UV absorption, the unstained histological preparations of normal tracheal mucosa revealed an intense darkening of the cell nuclei due to the absorption of nucleic acid; although the nuclei of the papillomata had almost the same DNA content as normal tissue, they were about twice as large and showed only slight UV absorption. This difference was also observed in the variously stained cells. An analysis of the papillomata nuclei revealed a diminished correlation between nuclear volume and content of nucleic acids or histones.

Changes in the nuclear volume, widening in the distribution curve of the histograms, and the decrease in the correlation of nuclear volume and nucleic content were associated with the extent of the malignancy.

- 0481 INDUCTION OF BLADDER TUMORS IN MICE WITH DIBUTYLNITROSAMINE. (E.) Bertram, J. S. (Christie Hosp., Manchester, England) and A. W. *Brit J Cancer* 24(2):352-359, 1970.

The carcinogenic activity of high doses (30 mg/kg/day) and low doses (7.6 mg/kg/day) of dibutylamine (DBN) given continuously in drinking water was studied in C57BL/6 mice. The high dose produced bladder tumors in 44 mice (48%) after a cumulative dose of 7400 mg/kg with a tumor induction time of 240 days, while the low dose produced bladder tumors in 19 mice (21%) after a mean cumulative dose of 2000 mg/kg with an induction time of 260 days. Bladder tumors occurred predominantly in males with the male to female ratios of 4.4 and 8.5 at the high and low doses, resp. Esophageal tumors were observed in all but 9 animals, while 5 animals receiving the lower dose of DBN developed forestomach carcinomas, and 13 animals (5 in the higher dose group and 8 in the lower dose group) developed tumors of the soft palate or tongue.

- 0482 UPPER RESPIRATORY TRACT TUMORS INDUCED IN SYRIAN HAMSTERS BY N-METHYL-N-NITROSOUREA. (E.) Herrold, K. McD. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Int J Cancer* 6(2):217-222, 1970.

The upper respiratory tract of Syrian hamsters was histologically examined following intratracheal instillation of N-nitroso-N-methylurea (0.5 mg/kg daily for 2½ months). Respiratory distress occurred in 8 animals after 5 to 7 months, 1 animal died at 8 months, and 1 animal survived to 11 months. Tumors developed in the nasopharyngeal tube, pharynx, trachea, bronchi, esophagus, and forestomach wall. Of the 10 hamsters exhibiting multiple tumors, although no distant metastases were observed. All tumors were epidermoid carcinomas and many were centric in origin. N-nitroso-N-methylurea is a highly effective carcinogen affecting the upper respiratory tract of Syrian hamsters.

- 0483 SELECTIVE INDUCTION OF CARCINOMAS OF THE GLANDULAR STOMACH BY N-METHYL-N-NITROSO-N'-ACETYLUREA IN RATS. (Ger.) Druckrey, H. (Max Planck Inst. Immunobiol., Freiburg, Germany), Ivankovic and R. Preussmann. *Z Krebsforsch* 75:23-33, 1970.

A model for the induction of gastric cancer is presented; N-methyl-N-nitroso-N'-acetylurea administered to 13 BD rats (2mg/kg in drinking water 5 times for 330 days) produced carcinoma of the glandular stomach in the pyloric region in all of the animals approximately 80 days after the end of the treatment. Another group of 11 rats were given 4 mg/kg under the same conditions as above. C

surviving rats, 8 had extended and partially perforated gastric adenocarcinoma morphologically similar to the ones developed in the lower dose group, except for 2 cases of polymorphic sarcomas. Two rats of the higher dose group also had cerebral glioma, and 2 rats had malignant neurinoma of the peripheral nervous system, indicating absorptive effects at the nervous system level. A considerable similarity with human gastric adenoma was observed.

- 0484 EFFECT OF N-METHYL-N'-NITRO-N-NITROSOGUANIDINE ON THE CELL CYCLE AND CHROMOSOMES OF HUMAN EMBRYONIC LUNG CELL. (E.) Kelly, F. (Div. Pharmacol. Toxic., Food Drug Admin., Washington, D. C.) and M. Legator. *Mutat Res* 10(3):237-246, 1970.

The effects of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG, 0.5 µg and 1.0 µg/ml) on DNA synthesis, cell cycle, and chromosome structure of random and synchronized populations of heteroploid human embryonic lung cells (L-132) were determined by autoradiography and liquid scintillation techniques. The mitotic index of cells exposed to MNNG decreased to less than 10% of control values after 16 hr, then slowly increased toward normal levels. Cells exposed to MNNG while in the S phase remained in S phase while cells in the G₁ stage proceeded into S phase where the rate of DNA synthesis dropped 43% (1600 cpm to 900 cpm), although ³H-thymidine incorporation was increased (60% compared to 35% in control cells). Cells in the G₂ phase were not affected. MNNG lengthened the S phase (7 hr to 17 hr) and the time required for cells in the G₁ phase to reach division (9 hr to 16 hr). Chromosomes of cells in G₁ and early and mid-S stages were sensitive to the MNNG and exhibited chromatid breaks and exchange configurations, although late S and G₂ phase cells showed no chromosome abnormalities at metaphase of the first division after exposure.

- 0485 SPECIFIC EXCISION OF METHYLATION PRODUCTS FROM DNA OF *ESCHERICHIA COLI* TREATED WITH N-METHYL-N'-NITRO-N-NITROSOGUANIDINE. (E.) Lawley, P. D. (Roy. Cancer Hosp., London, England) and D. J. Orr. *Chem Biol Interact* 2(2):154-157, 1970.

Specific enzymatic removal (excision) of products of monofunctional alkylation from the DNA of *E. coli* by the mutagen and carcinogen N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was investigated. *E. coli* cultures were incubated with doses of tritium labeled MNNG in amounts of 100 and 1000 µg/ml, the DNA isolated, and the excision products determined. The major methylated component in DNA was 7-methylguanine (78%) at MNNG concentration of 0.74 mM; minor products included 3-methyladenine (2%) and 2-amino-6-methoxypurine (11%). No significant difference was observed between the B/r and B_{s-1} strains of *E. coli*.

- 0486 HISTOLOGY AND HISTOCHEMISTRY OF N-NITROSO-N-METHYLURETHAN INDUCED LESIONS OF THE LUNG IN MICE: WITH SPECIAL REFERENCE TO HYDROLASES. (Fr.) Caulet, T. (Fac. Med. Reims, France) and M. Pluot. *Z Krebsforsch* 74(3):227-235, 1970.

The effect of N-nitroso-N-methylurethan on lung parenchyma was studied in 50 white male mice (Swiss strain, 2 months old). The carcinogen was administered s.c. once a wk for 21 wk (1 mg for the first 5 injections and 0.2 mg thereafter; the mice were sacrificed 15 days-2 months after the end of the treatment. Histological examination revealed areas of eosin-staining cell proliferation, often covering the alveolar pattern; outside these areas the lung parenchyma was severely damaged by a process of reticular hypertrophic pneumonia. The tumor cells had high levels of succinic dehydrogenase, ubiquinone and α-naphthylesterase activities, mainly at the peripheral regions of the proliferative areas; leucine aminopeptidase, alanine aminopeptidase and lipase levels were also high, while cytochrome oxidase, monoamine oxidase, glutamate dehydrogenase and glucose-6-phosphate dehydrogenase activities were low. Acid phosphatase activity was highest in the alveolar macrophages (type III cells) while none or little was found in type I, type II cells and in the tumor cells. ATP-ase levels were high throughout the various lung structures and the tumor foci. Alkaline phosphatase activity was moderate in the bronchial coating, very high in bronchial capillaries and high in the granular alveolar (type II) cells. Minimal alkaline phosphatase activity was found within the tumor cells while very high activities were found in areas of hypertrophic reticular pneumonia and at the capillaries peripheral to the tumor cells, suggesting a possible relationship between alkaline phosphatase activity and the onset of transformation.

- 0487 CARCINOGENIC ACTION OF 8-HYDROXYQUINOLINE. (Rus.) Pliss, G. B. (USSR Minist. Publ. Hlth., Leningrad) and N. I. Volfson. *Vop Onkol* 16(8):67-71, 1970.

Carcinogenicity of 8-hydroxyquinoline (8-OQ) in rats and CC57W mice was studied under the following experimental conditions: I) 70 rats were given 100 mg 8-OQ in sunflower oil suspension s.c. once a wk for 730 days, a total dose of 10,500 mg; II) 39 rats received 15 mg 8-OQ in diet 6 times a wk for 729 days, a total dose of 9,360 mg; III) 62 rats were treated intravaginally with a 20% dist. water suspension of 8-OQ (20 mg twice a wk for 729 days, a total dose of 3,860 mg); IV) 32 mice received 1.5 mg 8-OQ s.c. 3 times monthly for 660 days, a total dose of 97.5 mg; V) 49 mice were given 1.5 mg 8-OQ in the diet 6 times a wk for 660 days, a total of 852 mg; VI) 46 mice were subjected to intercostal skin applications with a 0.75% benzene soln of 8-OQ (1.2 mg 3 times a wk for 656 days, a total dose of 334.8 mg; and VII) 46 mice were subjected to intravaginal applications of 2 mg 8-OQ twice a wk for 812 days, a total dose of 428 mg. The highest incidence of induced tumors occurred in the orally-treated rats

(approximately 50% of the surviving animals) and in the s.c.-treated mice (approximately 40% of the surviving animals) after a latency period of more than 1 yr. Of the rats subjected to s.c. treatment 2 developed lymphosarcoma in the ileocecal region and 2 had fibrosarcomas of the subcutaneous tissue; among the orally-treated rats 1 adenocarcinoma, 2 liver sarcomas, 1 uterine adenocarcinoma, 1 intestinal reticulosarcoma and 5 fibroadenomas of the mammary gland developed; of the intravaginally-treated rats 1 developed uterine cancer associated with a mammary gland fibroadenoma, 1 had a mammary gland fibroadenoma, 2 developed lymphadenosis and 1 developed thyroid cancer. Of the mice subjected to s.c., p.o. and skin application treatment, 7 developed pulmonary adenomas, 2 developed ovarian folliculomas and 5 developed liver hemangiomas. Intravaginal applications of 8-OQ produced no local tumors but 5 mice developed ovarian folliculomas, 4 had lung adenomas and 1 had liver hemangioma. 8-OQ seemed to be a weak carcinogen with resorptive action possibly affecting the hormonal balance.

- 0488 DEVELOPMENT OF INJECTION-SITE SARCOMATA IN RATS: A STUDY OF THE EARLY REACTIVE CHANGES EVOKED BY A CARCINOGENIC NITROQUINOLINE COMPOUND. (E.) Carter, R. L. (Roy. Cancer Hosp., London, England), M. S. C. Birbeck and J. D. B. Roberts. *Brit J Cancer* 24(2):300-311, 1970.

Early reactive changes in the development of sarcoma at the injection site after single doses of polymerized N-nitroso-2,2,4-trimethyl-1,2-dihydroquinoline (NTDQ) were followed in adult (25 mg, s.c.) and newborn (2.5 mg, s.c.) rats using microscopy, autoradiography, and colloidal carbon. The development of lesions proceeded from the non-specific acute inflammatory response of the first 3 days after injection, to more discrete developing granulomata with large mononuclear phagocytes (fibroblasts and macrophages), granulation tissue, and multinucleate giant cells (produced by the fusion of adjacent histiocytes), and finally to the fully developed granulomata at about 10 days. In autoradiographic studies using ^3H -thymidine, the mononuclear cells showed an extensive nuclear labeling during the first 10 days after NTDQ injection which dropped slightly but remained at raised levels throughout the experiment, and the multinucleate giant cells showed no detectable nuclear labeling. Carbon uptake measurements confirmed the lack of proliferative activity in the giant cells and showed minimal phagocytic activity. Colloidal carbon studies also indicated that during the first 5 days after NTDQ injection lymphatic vessels were dilated but local connective tissue barriers quickly closed off the lesions from surrounding dermal tissues.

- 0489 EFFECT OF A POTENT CARCINOGEN, 4-NITROQUINOLINE 1-OXIDE, AND ITS REDUCED FORM, 4-HYDROXYLAMINOQUINOLINE 1-OXIDE, ON BACTERIAL AND BACTERIOPHAGE GENOMES. (E.) Yamamoto, N. (Temple U. Sch. Med., Philadelphia, Pa.), S. Fukuda and H. Takebe. *Cancer Res* 30(10):2532-2537, 1970.

The effect of the carcinogen 4-nitroquinoline-1-oxide (4NQO) and a metabolite of this agent, 4-hydroxylaminoquinoline-1-oxide, on *Salmonella typhimurium* and on bacteriophage activity was investigated. Tumor strains of *S. typhimurium* which could not grow in the presence of 4NQO (4NQO-sensitive mutants) were also sensitive to UV (2 ergs/mm²/sec) and to β -propiolactone. 4NQO-sensitive mutants were of 2 types: host cell reactivation minus mutants which lacked repair activity for the UV-damaged superinfecting phage, and recombination-deficient mutants. Exposure of host cell reactivation minus mutants and wild-type strains to 4NQO, β -propiolactone and UV induced prophages from these strains, but not from recombination-deficient cells; prophage induction from host cell reactivation minus cells was more efficient than prophage induction from wild-type strains. The highly carcinogenic metabolic intermediate of 4NQO, 4-hydroxylaminoquinoline-1-oxide inactivated *Salmonella* phage *in vitro*, while 4NQO itself did not. No difference in inactivation was found on the various indicator hosts when 4-hydroxylaminoquinoline-1-oxide-treated phage was assayed on host cell reactivation minus mutants, on recombination deficient mutants, or on wild-type strains lysogenic for phage P221b. This finding appears to imply that the 4-hydroxylaminoquinoline-1-oxide-damaged phage genome is not reparable by the hosts. No significant increase in recombination was found in recombination-deficient mutants, although the frequency of recombination was increased between the 4-hydroxylaminoquinoline-1-oxide-treated phage and the prophage P221b in wild-type strain cells and host cell reactivation minus mutants. The recombination process between the damaged phage and the prophage P221b seems to be closely related to the bacterial recombination mechanism.

- 0490 EARLY EVENTS IN *IN VITRO* CARCINOGENESIS WITH 4-NITROQUINOLINE-1-OXIDE: II. MECHANISM OF INCORPORATION AND BINDING OF THE CARCINOGEN. Kuroki, T. (Cancer Res. Lab., Tohoku U., Sendai, Japan), R. Kanamaru and H. Sato. *Gann* 61(4):373-382, 1970.

Cultures of hamster embryo cells were treated with a solution of ^{14}C -labeled 4-nitroquinoline-1-oxide (final concentration, $10^{-5.5}\text{M}$) to investigate the mode of incorporation and the binding of this compound to the cells. The carcinogen was incorporated within 30-60 min and was bound to macromolecules of hamster embryo cells with a characteristic time course. The binding persisted over 72 hr after treatment. The rate of incorporation was directly proportional to concentration of the carcinogen and inversely proportional to the cell number. Specific inhibitors of RNA, DNA and protein synthesis such as hydroxyurea, actinomycin D and puromycin had no effect on the incorporation of 4-nitroquinoline-1-oxide. No competent cellular condition or phase in which binding and incorporation of the carcinogen occur appears to exist.

- 0491 NUCLEOLAR ALTERATIONS OF ALVEOLAR EPITHELIAL CELLS IN RATS FOLLOWING A SINGLE INJECTION OF 4-NITROQUINOLINE-1-OXIDE. (E.) Haya

Y. (Shionogi Res. Lab., Osaka, Japan) and T. Hasegawa. *Gann* 61(4):347-352, 1970.

Male rats received a s.c. injection of 4-nitroquinoline-1-oxide suspended in olive oil (15 mg/kg); they were killed 2-48 hr later, and their lungs were subjected to electron microscopic examination to investigate nucleolar alterations in the alveolar epithelial cells. Nucleolar alterations characterized by disintegration of the reticular structure, and segregation of the granular and fibrillar components into separate zones, occurred in the alveolar epithelial cells, both of Type I and II, as well as in the epithelial cells lining the alveolar ducts and the terminal bronchioles. These alterations appeared prominently 6-12 hr after injection. At the 48th hr the reticular structure of the nucleolus appeared to be reorganized in association with an abundance of the granular component. A series of quinoline derivatives with carcinogenic activity, including 4-hydroxyaminoquinoline-1-oxide, 2-methyl-4-nitroquinoline-1-oxide, 6-methyl-4-nitroquinoline-1-oxide and 6-chloro-4-nitroquinoline-1-oxide, was found to produce these nucleolar alterations. Non-carcinogenic quinolines showed no such effect.

0492 COMPARATIVE STUDIES ON THE KINETICS OF THE NEOPLASTIC COMPETENCE IN MICE. (E.) Vesselinovitch, S. D. (Pritzker Sch. Med., U. Chicago, Ill.), N. Mihailovich and L. Itze. *Cancer Res* 30(10):2548-2551, 1970.

Mice of both sexes were administered i.p. injections of urethan (3-12 injections at 3-day intervals commencing on the 1st, 4th or 175th day of life) totaling 1.5-12 mg/g body wt, in order to compare tumor spectra and incidence resulting from the administration of urethan at different age periods. The non-treated controls developed leukemias, hepatomas, lung adenomas, Harderian gland adenomas, and ovarian tumors during their 3rd yr of life. Neonatal exposure to urethan had a positive effect on the development of the same tumor types; the incidence of hepatoma, lung adenoma and Harderian gland adenoma in mice receiving urethan at day one was 86.0%, 30.0% and 8.0%, resp., after a 1-yr observation period. Urethan administered to adult mice at the 6-12 mg/g body wt level resulted in a 2-3 fold increase over controls of lung and Harderian gland adenomas and ovarian tumors which occurred in the 2nd yr of life. The incidence of each of these primary tumors was directly related to the dose of the carcinogen administered. No leukemia developed in the adult animals in spite of the increased dose, while hepatomas were observed in a low incidence only in a group of mice exposed to the highest dose of urethan. Regardless of the tendency of tissues to develop spontaneous tumors, the tumor response to carcinogen with regard to incidence and location appeared to depend on the age of the animal at first exposure to urethan.

0493 PULMONARY ADENOMA IN SWISS MICE RECEIVING URETHANE. VIII. EFFECT OF PHENOBARBITAL. (Fr.) Adenis, L. (Inst. Res. Cancer Lille, France),

M. N. Vlaeminck and J. Driessens. *C R Soc Biol* 64(3):560-562, 1970.

The mechanism of urethan carcinogenesis in mouse lung was studied by using phenobarbital as a structurally related compound. Four groups of animals (25 males and 25 females each, 3-5 months-of-age) were treated as follows: group I received both phenobarbital (0.1 ml of a 2% soln s.c. for 6 consecutive days) and urethan (1 ml of a 4% soln s.c., single dose on the 8th day of the experiment); group II received phenobarbital only (as above); group III received urethan only (as above) and group IV received 1 ml urethan and 15 days later 0.1 ml phenobarbital for 8 consecutive days. The animals were sacrificed at 8 months-of-age. All the animals of group III developed tumors. Animals in group I developed an average of 9 tumors as compared to the average of 1 in group II and 21 in group III, while those in group IV developed an average of 15 tumors. Phenobarbital exhibited no carcinogenic effect, but it had an anti-urethan effect when administered prior to urethan and no effect when injected 15 days after urethan administration.

0494 MEDIASTINAL LYMPHOMA OF THE URETHAN TREATED SWISS MOUSE. X. MICROSCOPY OF GERM-FREE ANIMALS AFTER 10 WEEKS OF TREATMENT. (Fr.) Sacquet, E. (Inst. Res. Cancer Lille, France), F. Puvion, L. Adenis and A. Demaille. *C R Soc Biol* 164(3):557-560, 1970.

The effects of urethan on 35 germ-free Swiss Webster mice 2 months-old were studied. The animals received ethyl urethan (0.1% in drinking water for 10 wk) and were sacrificed 5-9 months from the start of the experiment. Liver, spleen, thymus, lung, kidney and lymphatic ganglia were subjected to routine histological examination and electron microscopy. Both light and electron microscopy revealed morphologically identical lung adenomas in germ-free and conventional animals. Pulmonary epitheliomas occurred in 22 animals while thymic lymphoma with no leukemia as revealed by histology or hematology occurred in 2 germ-free mice. A lower incidence of hyperplasia of splenic Malpighian corpuscles and hepatic angiomatosis was noticed in 22 germ-free animals compared to conventional mice. Ultrastructurally, lymphoid hyperplasia of enlarged cells with large nuclei and free ribosome-rich cytoplasm was observed. Mediastinal lymphomas were rare, compared to the conventional Swiss mouse. No virus particles were detected in the lung tumors or in mediastinal lymphomas in the germ-free mouse.

0495 ISOLATION AND PURIFICATION OF TYPE A VIRUS-LIKE PARTICLES FROM THE CYTOPLASM OF AN ETHYL URETHAN-INDUCED MEDIASTINAL LYMPHOMA. (Fr.) Kerckaert, J. P. (Inst. Res. Cancer, Lille, France), J. Montreuil, M. C. Doyennette, F. Puvion, M. N. Vlaeminck, A. Vebert, A. Demaille and J. Driessens. *C R Acad Sci* 271(6):624-627, 1970.

Highly purified type A2 virus-like particles were obtained from the cytoplasm of urethan-induced

mediastinal lymphoma cells in Swiss mice. Sedimentation of the virus-like particle fraction occurred with the mitochondrial fraction from a 0.25 M sucrose solution homogenate. Addition of Triton X100 to the mitochondrial fraction and isopicnic ultracentrifugation in a continuous cesium chloride gradient resulted in a low yield isolation of the virus-like particle fraction, density = 1.28. This yield was improved by ultracentrifugation of the mitochondrial fraction through a 2-layer system of cesium chloride soln ($d=1.35$ and $d=1.27$), so that clusters of virus-like particles were concentrated at the separation boundary between the 2 cesium chloride soln. Electron microscopy revealed no cytoplasmic contamination of the virus-like particle clusters. Negative dye treatment revealed the presence of bridges of yet unknown nature linking the particles into clusters. Electron microscopy revealed that isolated viral particles were morphologically identical to those contained in the cytoplasm.

- 0496 THE SIGNIFICANCE OF PERINATAL AGE PERIODS AND THE DOSE OF URETHAN ON THE TUMOR PROFILE IN THE MRC RAT. (E.) Kommineni, V. R. C. (U. Nebraska Coll. Med., Omaha), M. Greenblatt, N. Mihailovich and S. D. Vesselinovitch. *Cancer Res* 30(10):2552-2555, 1970.

Fetal, newborn, weanling and young adult rats received i.p. injections of urethan (0.5-6 mg/g body wt) 2 or 4 days prenatally, or at 3-day intervals commencing at 1, 28, or 46 days after birth; the aim was to examine the role of the prenatal, neonatal and postweaning age periods in carcinogenesis at various sites of the body. Rats treated with urethan as newborns showed the highest incidence and the broadest spectrum of neoplasms. At 6 mg/g body wt of urethan, a 30% mortality rate was observed in newborn rats; however, tumor response was clearly more dependent upon the age of the animals at the time of the carcinogenic treatment than upon the administered dose of the carcinogen. Newborn rats developed tumors at specific sites in significantly higher incidence than the animals treated at other age periods. Rats which were exposed to urethan *in utero* developed liver tumors and Anitschkow cell sarcomas of the heart. Neonatally treated animals had gliomas of the brain, neurilemmomas, and embryonal kidney tumors in addition to liver tumors and heart sarcomas. The urethan-treated weanlings showed no heart or brain neoplasms but did develop the other types of tumors with low frequency.

- 0497 THE INDUCTION OF MALIGNANT MELANOMAS IN SYRIAN WHITE HAMSTER BY NEONATAL EXPOSURE TO URETHAN. (E.) Vesselinovitch, S. D. (Pritzker Sch. Med., U. Chicago, Ill.), N. Mihailovitch and W. R. Richter. *Cancer Res* 30(10):2543-2547, 1970.

Hamsters received i.p. injections of urethan (0.5 mg/g body wt) before reaching 24 hr-of-age and on 4 subsequent occasions at 3-day intervals, with the purpose of investigating the induction of malignant melanoma by neonatal exposure to the carcinogen.

The urethan-treated animals developed malignant melanomas which metastasized to regional lymph nodes, lungs, kidneys, and liver (62% of the male and 40% of the females developed tumors). None of the untreated controls showed any melanomas either clinically or at autopsy. The melanoma-bearing hamsters had significantly shorter life-spans than did the untreated controls. (e.g., age at death was 82 wk and 91 wk for treated and untreated hamster resp.) Other tumors developed at a low frequency by the urethan-treated hamster but not by untreated controls included stomach papillomas, hepatocarcinomas, and kidney adenomas.

- 0498 ADRENAL TUMORS AND ENDOCRINE LESIONS INDUCED IN SYRIAN HAMSTERS BY URETHANE INJECTED DURING SUCKLING PERIOD. (E.) Matsuyama, M. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan) and H. Suzuki. *Brit J Cancer* 24(2):312-318, 1970.

Urethan, in 10% saline solution, was injected s.c. into suckling hamsters (1 mg/kg body wt) once a week for 6 wk, with the result that most of the hamsters surviving for more than a year developed nodular hyperplasia of the adrenal cortex and of the pancreatic islets. The experiment was terminated at the end of 124 wk when the last animal died. Eight adrenal cortical tumors, including 2 metastasizing ones, and a β -cell tumor of the pancreatic islets were also found in the 28 treated hamsters. Other lesions included adenomatous hyperplasia of the thyroid, splenic nodules, melanomas of the skin and eyes, papillomas in the forestomach, hemangiomas and cysts in the liver, and an adenocarcinoma of the exocrine pancreas. It may be that there are progressive steps from the hyperplastic nodules to the development of the tumors, a hypothesis supported by the histology of the adrenal lesions.

- 0499 SHORT TERM TEST FOR EVALUATING POTENTIAL CARCINOGENIC ACTIVITY OF TOBACCO CONDENSATES. (E.) Healey, P. (Huntingdon Res. Ctr., London), L. E. Mawdesley-Thomas and D. H. Barry. *Nature* 228(5275):1006, 1970.

Image-analysis techniques were used to estimate specific esterase enzyme activity in the skin of mice painted with tobacco condensates or other known carcinogenic hydrocarbons. Sections were taken of areas of mouse skin painted with various condensates or agents and subjected to image analysis. A direct relationship was found between area of esterase activity and known carcinogenic activity of the compound. High tumor yields (77 and 48% of treated animals) were found for tobacco condensate A in doses of 100 and 60 mg, and this condensate at these doses produced areas of esterase activity of 36 and 64 μm^2 , resp. High esterase activity areas were also found for tobacco condensate C at doses of 36 and 60 mg (areas were 522 and 339 μm^2 , resp). Urethane produced an esterase activity area of 1,392 μm^2 . The area of esterase activity test serves to provide a rapid screen for potential carcinogenic hazards in tobacco condensates.

- 0500 CANCER IN MZ AND DZ TWINS. (E.) Cederlöf, R. (Karolinska Inst., Stockholm, Sweden), B. Floderus and L. Friberg. *Acta Genet Med Gemellol* 19(1-2):69-74, 1970.

The classical twin method was used to analyze mortality and morbidity in cancer and concordance rates for monozygous (MZ) and dizygous (DZ) twins. The influence of smoking habits on cancer development were also analyzed. (Cancer data obtained from the Swedish Cancer Registry and the Registry of Causes of Death). No heredity influence could be shown in the development of cancer although genetic factors may be relevant to the localization of the tumor (1 MZ pair were concordant for cancer of the stomach, 2 MZ pairs were concordant for cancer of the uterus, 1 DZ pair were concordant for cancer of the stomach and 2 DZ pairs were concordant for cancer of the uterus/prostate). A significant difference in cancer morbidity between smokers and nonsmokers was observed only in the male group (63-82 yr of age) where 7.6% of the smokers exhibited cancer compared to 4.3% of the nonsmokers. Despite the small numbers the association between smoking and lung cancer is evident.

- 0501 DIFFERENTIAL CYTOLOGICAL AND CYTOCHEMICAL RESPONSES OF VARIOUS CULTURES FROM MOUSE TISSUES TO REPEATED EXPOSURES TO PUFFS FROM THE GAS PHASE OF CHARCOAL-FILTERED FRESH CIGARETTE SMOKE. (E.) Leuchtenberger, C. (Swiss Inst. Exp. Cancer Res., Lausanne) and R. Leuchtenberger. *Exp Cell Res* 62(1):161-172, 1970.

The morphological and cytochemical effect on DNA of repeated exposure to puffs of the gas phase from charcoal-filtered fresh cigarette smoke was studied in 3 types of primary cultures from mouse tissues (kidney tissue, embryonic lung organ, and lung explants) and in the 3T3 established cell line. Primary kidney tissue, embryonic lung organ, and lung explants (with outgrowing macrophages and epitheloid cells) were unaffected by the repeated exposures. The 3T3 cells were markedly stimulated by the puffs of the gas phase (independent of the puff volumes) with an enhancement of mitosis, cellular atypism (increase of DNA in interphase cells and metaphase chromosomes), tendency to nuclear fusion, and piling up of cells, but no morphological cell transformation was observed.

- 0502 RAT GASTRIC SECRETION AND MUCOSAL SEROTONIN FOLLOWING CHRONIC ORAL NICOTINE INTGESTION. (E.) Thompson, J. H. (U. California Los Angeles Sch. Med.), M. Angulo and C. A. Spezia. *Res Commun Chem Path Pharmacol* 1(6):721-732, 1970.

Gastric secretion (ml/100 g) and gastric mucosal serotonin ($\mu\text{g}/\text{tissue}$) were measured in 2-hr pylorus-ligated Sprague-Dawley rats after 2 weeks of exposure to nicotine (100 $\mu\text{g}/\text{kg}/\text{day}$ or 1000 $\mu\text{g}/\text{kg}/\text{day}$) in drinking water with and without atropine (100 $\mu\text{g}/\text{kg}$, s.c.) injected during ligation. Nicotine (1000 $\mu\text{g}/\text{kg}/\text{day}$) significantly increased gastric secretion (0.4 to 0.95) while atropine reduced gastric secretion in both controls and nicotine-treated animals

to 0.1. Total gastric mucosal serotonin dropped from the control level of 2.44 to 2.03 with the lower dose of nicotine and to 1.74 with the higher dose; atropine slightly reduced the serotonin levels of each group (2.28, 1.74, and 1.46, resp.). The increase in gastric secretion and depletion of mucosal serotonin may be related.

- 0503 CYTOGENETIC STUDIES ON WOMEN USING ORAL CONTRACEPTIVES AND THEIR PROGENY. (E.) McQuarrie, H. G. (Gynec. Obstet. Clin. Inc., Salt Lake City, Utah), C. D. Scott, H. S. Ellsworth, J. W. Harris and R. A. Stone. *Amer J Obstet Gynec* 108(4):659-665, 1970.

Users of oral contraceptives and children of users of oral contraceptives were subjected to cytogenetic studies. Subjects included 50 babies born to mothers after oral contraceptive use (sequential mestranol and mestranol with chlormadinone), 23 women using oral contraceptives (mestranol or norethindrone), and 20 women who reportedly had never used oral contraceptives. Dermatoglyphic studies were also performed on the babies. One baby had D/G translocation Mongolism. In the oral contraceptive users, increased chromosome breakage and satellite association were observed. Such abnormalities were more frequent in contraceptive users than in non-users (18 users and 7 non-users had breaks).

- 0504 CERVICAL CYTOLOGY AND SEQUENTIAL BIRTH CONTROL PILLS. (E.) Dougherty, C. M. (Louisiana St. U. Med. Ctr., New Orleans). *Obstet Gynec* 36(5):741-744, 1970.

The correlation of cytological abnormalities, possibly associated with carcinoma *in situ* of the cervix, and sequential contraceptive pills was studied in 1983 women. Initial cytologic smears were negative in 1933 of these women and positive in 50 women (cervical carcinoma in 15 cases and atypical epithelial hyperplasia in 35 cases). The incidence of cytologic abnormalities was observed at various periods after commencement of a course of oral contraceptives, with the result that after 14-26 menstrual cycles on the sequential contraceptive pills, 1021 women showed negative smears, 16 showed atypical and 7 showed positive smears. This finding yields a rate of atypical and positive smears/1000 cycle of 15 and 7, resp., after 14-26 cycles. The results indicated that the observed rate of occurrence of cytologic abnormalities in patients on contraceptive pills was about twice as high as the rate expected in control subjects. None of the patients studied developed mammary carcinomas, adenocarcinomas or stromal sarcomas, but 7 benign mammary masses were found.

- 0505 THE EFFECT OF ORAL CONTRACEPTIVES ON THE HISTOLOGY OF CARCINOMA OF THE BREAST. (E.) Penman, H. G. (U. Otago Med. Sch., Dunedin, New Zealand). *J Path* 101(1):66-68, 1970.

The histological appearance of a malignant tumor in the breast of a woman who had been taking oral con-

traceptives was examined. The patient, a 27 yr-old mother of 2, had used 3 different brands of birth control pills for 3 yr when she developed a tumor in her right breast. Mastectomy was performed, and the tumor was diagnosed as an extensively infiltrating type of comedocarcinoma. The intraduct portion of the tumor displayed prominent "colostrum corpuscles", and there were metastases to the lymph nodes which were composed of markedly eosinophilic cells. The occurrence of colostrum-like foamy cells in the cytoplasm of the tumor cells appears to agree with the suggestion that these cells are associated with hyperplastic disorders correlated with hormonal disturbances of the type brought on by oral contraceptives.

- 0506 A PATIENT WITH A METASTASIZED OVARIAN CARCINOMA, CURED (?) AFTER CYTOSTATIC TREATMENT; DEATH FROM ACUTE MYELOGENIC LEUKEMIA. (Dut.) Smit, C. G. S. (Diakonessen Hosp., Groningen, Netherlands) and L. Meyler. *Nederl T Geneesk* 114 (39):1620-1623, 1970.

Death from acute myelogenous leukemia of a 44-yr-old woman who had received extensive cytostatic treatment for bilateral ovarian papilliferous cystadenomata (which had metastasized to the peritoneum and to the omentum is reported. The patient underwent resection of the cystadenomata and of the omentum and was treated with cyclophosphamide (50 mg 3 x daily for 24 months) and x-ray therapy for 3 months (9000 r); 2 yr after the resection, she was free of metastases. However, 2 yr later a second laparotomy revealed an inoperable tumor in the pelvic cavity, and carcinomatous metastases were found in the peritoneum similar to those excised 4 yr earlier. Treatment with thiotepea was commenced (15 mg/wk), and 11 months after the laparotomy, the metastases seemed to have disappeared. However, anemia, thrombopenia and leukopenia were now observed, and the patient died from acute myelogenous leukemia.

- 0507 MULTIPLE MYELOMA AND ACUTE MYELOMONOCYTIC LEUKEMIA: REPORT OF FOUR CASES POSSIBLY RELATED TO MELPHALAN. (E.) Kyle, R. A. (Mayo Clin., Rochester, Minn.), R. V. Pierre and E. D. Bayrd. *New Eng J Med* 283(21):1121-1125, 1970.

Four patients, 1 suffering from a plasma-cell dyscrasia with systemic amyloidosis, and 3 suffering from typical multiple myeloma involving anemia, elevated sedimentation rate, monoclonal serum peak, Bence-Jones protein in the urine, lytic bone lesions, and increased myeloma cell counts in the marrow, were treated with melphalan (L-phenylalanine mustard) for periods of 30-57 months; all 4 patients developed acute myelomonocytic leukemias of rapid progression. The remote likelihood of chance association of acute leukemia and multiple myeloma (the probability of leukemia occurring in 250 cases of myeloma is 1:50,000), the known effect of alkylating agents on DNA, the fact that the leukemia was myelomonocytic, and the long period of treatment with melphalan all suggest that melphalan therapy played an etiologic role in the development of leukemia in these cases.

- 0508 LYMPHOCYTE TRANSFORMATION OBSERVED IN SULFAMYLON AGRANULOCYTOSIS. (E.) Maurel L. H. (Dartmouth Med. Sch., Hanover, N. H.), P. Andrews, F. Rueckert and O. R. McIntyre. *Plast Reconstr Surg* 46(5):458-462, 1970.

DNA synthesis (^3H -thymidine incorporation) in the lymphocytes of a patient who had developed Sulfamylon agranulocytosis during treatment with Sulfamylon cream (α -amino-p-toluenesulfonamide) and in lymphocytes of 4 control subjects (2 normal and 2 hospitalized patients treated with Sulfamylon cream for longer than a month) was measured in the presence of Sulfamylon acetate (1 mg%) or its major metabolite, sulfamylbenzoic acid (1 mg%). ^3H -Thymidine incorporation (cpm) was 2.5 times greater with sulfamylbenzoic acid (592) than in its absence (232) in the lymphocytes of the patient who had agranulocytosis although Sulfamylon (200) had not affected the incorporation. Lymphocyte transformation did not occur with either Sulfamylon or its metabolite in the 2 normal subjects or in the other control patients.

- 0509 A CASE OF LEUKEMIA FOLLOWING EXPOSURE TO INSECTICIDE. (E.) Hoshizaki, H. (Osaka Red Cross Hosp., Japan), Y. Niki, H. Tajima, Y. Terada and A. Kasahara. *Acta Haemat Jap* 32(4):672-677, 1970.

A case report of a Japanese sanitation employee with acute leukemia apparently associated with occupational exposure to the insecticides benzene hexachloride and chlorophenothane (DDT) is described. In the course of his work, the patient, a 44-yr-old male, sprayed these agents on houses and into sewers. He neglected to wear a face mask and probably inhaled the insecticides over the 8-yr period of his employment. On autopsy, abundant hemosiderin was found in each organ, especially in the liver, spleen and lymph nodes; no infiltration of leukemic cells into the liver and spleen was observed. The final diagnosis was acute leukemia with hypoplastic marrow and hemosiderosis. Possibly, exposure and resorption of chlorophenothane and benzene hexachloride via the alveoli led to aplastic anemia which then transformed into acute leukemia.

- 0510 NICKEL CARBONYL POISONING: REPORT OF TWO CASES. (E.) Vuopala, U. (Dept. Med. U. Oulu, Finland), E. Huhti, J. Takkunen and M. Huhti. *Ann Clin Res* 2(3):214-222, 1970.

The symptomatic effects of nickel carbonyl gas exposure on 25 industrial workers were observed; nickel carbonyl gas is a lethal poison and putative carcinogen. All patients had temporary or continuous dyspnea, and most had a persistent feeling of fatigue and weakness, especially ocular weakness. Nausea, cough, liver tenderness, and toxic pneumonitis were other common symptoms. Laboratory studies showed that the nickel content in the urine of patients, initially elevated as high as 900-1000 mg/l, returned to normal levels (less than 100 mg/l) by 1 wk after exposure to nickel carbonyl gas. In 2 of the patients died, and in all cases symptoms

emitted in time. Any bearing of acute poisoning on carcinogenesis seen with chronic inhalation of nickel carbonyl remains to be established.

- 511 CLINICAL STUDIES ON TUMOR OF THE URINARY BLADDER: I. STATISTICAL AND CLINICAL STUDIES ON TUMOR OF THE URINARY BLADDER. (*Jap.*) Kajima, E. (Nara Med. U., Japan), T. Hiramatsu, Y. Motomiya, K. Iriya, I. Hayashi and M. Ishikawa. *Exp J Urol* 61(8):783-804, 1970.

marked male predominance was observed in 150 cases of primary urinary bladder tumor studied at Nara Medical University, Japan, with 126 of the patients being male. The age distribution of the patients with urinary bladder tumors ranged from 3-84 yr, and the maximum incidence occurred in the 5th decade of both sexes. Occupational distribution of 89 patients with urinary bladder cancer revealed a remarkably frequent occurrence in workers in agriculture and forestry. One patient had been exposed to aniline dyes for 7 yr. A correlation between cigarette smoking and the development of urinary bladder tumors was significant in the present studies. In males, 47 patients (90.2%) of 52 cases and 71 patients (72.4%) of 98 controls were smokers. In females, 7 patients (63.3%) of 11 cases and 9 patients (16.7%) of 54 controls were smokers. Single tumors of the urinary bladder were noticed in 93 of 150 patients (62.0%). Fifty of 93 tumors (53.8%) were located on the lateral wall, 19 (20.4%) in the trigone, 9 (9.7%) on the posttrigone, 8 (8.6%) in the bladder neck, 6 (6.4%) on the vault, and 1 (1.1%) on the anterior wall. In 96 of 98 cases receiving histological classification, tumors were found to be transitional cell papilloma and carcinoma. The 5-yr survival rate, dated from the onset of symptoms, was zero in untreated cases, 50% in patients treated with suprapubic excision of tumors.

- 0521 CHROMOSOME AND CHROMATID-TYPE ABERRATIONS INDUCED BY COBALT⁶⁰ IRRADIATION AND TRITIATED URIDINE IN HUMAN LEUKOCYTE CULTURES. (E.) Lindahl-Kiessling, K. (Inst. Med. Genet. Zoophysiology, U. Uppsala, Sweden), B. Santesson and J. A. Book. *Chromosoma* 31(3):280-284, 1970.

Cobalt⁶⁰ irradiation and ³H-uridine irradiation were administered to cultures of human leucocytes in order to observe the chromosome and chromatid-type aberrations induced by this treatment; phytohemagglutinin was added to cultures after one exposure to ⁶⁰Cobalt (200-600 rads every hr) or ³H-uridine irradiation (30 µC/ml) of medium. Irradiated cells were collected at the time of their first mitotic event. In the cultures treated with ³H-uridine mainly breaks of chromatid type were found (129 chromatid aberrations/1461 cells analyzed), whereas the ⁶⁰Co irradiated cells have only breaks of chromosome type as long as the irradiation takes place before the onset of DNA synthesis (73 cells with chromosome aberrations, maximum and 9 with chromatid aberration, maximum). Apparently, ³H-uridine damages localized single stranded DNA loops separated during transcription in RNA synthesis and which are inaccessible to repairing. The results seem to indicate that the subunit of the chromosome as revealed by radiation is single-stranded DNA, and that the chromosome or chromatid continuity depends on 1 DNA double helix strand.

- 0522 EFFECT OF γ-RAYS ON INFECTIVITY AND CAPACITY FOR NUCLEAR-ASSOCIATED AND CYTOPLASMIC DNA REPLICATION OF FV3 IN CHICK EMBRYO FIBROBLASTS. (E.) Aubertin, A. M. (I. N. S. E. R. M., Strasbourg, France), C. Decker and A. Kirn. *Radiat Res* 44(1):178-180, 1970.

Frog virus 3 was grown in chick embryo fibroblast culture, and irradiated with γ-rays produced by ⁶⁰Co irradiation at a rate of 600 rads/min in order to investigate the effect of γ-rays on the virus' ability to infect and to replicate nuclear and cytoplasmic DNA. γ-Rays produced a dissociation of the capacities for infectivity, nuclear-associated DNA replication, and cytoplasmic DNA replication. When the amount of DNA synthesis induced by irradiated virus was expressed as a percentage of that induced by nonirradiated virus, the inactivation of the capacity for DNA replication (nuclear as well as cytoplasmic fraction) followed a simple exponential law. The rate of inactivation by γ-rays of the capacity for nuclear-associated DNA replication (37% inactivation dose was 8×10^5 rads) was half that of the capacity for cytoplasmic DNA replication (37% inactivation dose was 4×10^5 rads). This indicates that the synthesis of DNA which appears in the cytoplasm required more cistrons than the synthesis of the nuclear-associated DNA, and that the passage from cytoplasmic DNA to the virions required further protein synthesis. The capacity of frog virus 3 to inhibit host-cell DNA replication was not affected by γ-rays.

- 0523 DOUBLE-STRAND BREAKS IN THE DNA OF A MURINE LYMPHOMA CELL AFTER X-IRRADIATION. (E.) Lehmann, A. R. (Roy. Cancer Hosp. Lab., Belmont, Surrey, England) and M. G. Ormerod. *Biochem Biophys Acta* 217(2):268-277, 1970.

Double-stranded DNA scissions produced by X-irradiation of murine lymphoma cells were studied by measuring the molecular wt of the DNA of irradiated cells. Murine lymphoma cells (strain L5178Y) were labeled with tritiated thymidine, exposed to 220 kV X-rays and lysed on neutral sucrose gradients; the molecular wt of the released DNA was measured by rate of sedimentation through the gradients. Only when the speed of centrifugation was less than 20,000 rpm was sedimenting DNA pure and unaggregated, and at this speed did the sedimentation of the DNA truly reflect its molecular wt. Double-strand breaks were formed in the DNA of murine lymphoma cells as single events with an efficiency of 2900 ± 400 eV/break. After X-ray doses of more than 20 krad, these breaks were not rejoined on post-irradiation incubation. The molecular wt of DNA from unirradiated cells was at least 3×10^9 ; DNA molecules of molecular wt less than 10^9 were usually sedimented freely under appropriate conditions.

- 0524 THE RESPONSE OF STEM CELLS OF INTESTINAL MUCOSA TO IRRADIATION WITH 14 MeV NEUTRONS. (E.) Withers, H. R. (U. Texas M.D. Anderson Hospital, Tumor Inst., Houston), J. T. Brennan and M. M. Brenner. *Brit J Radiol* 43(515):796-801, 1970.

The survival and damage-repair reactions of jejunal crypt cells of female mice exposed to whole-body X-ray- and neutron-irradiation were studied. Mice were subjected to doses of 100-135 rads of 200 kV X-radiation or 82-142 rads of 14 MeV neutrons, and the survival and repair of crypt cells in the intestinal mucosa were assayed. Slopes of dose survival curves for X-ray- and neutron-irradiation were similar, the shoulder on the neutron curve being narrower than the shoulder of the X-ray curve with 10^2 clonogenic cells surviving 675 rads of X-ray irradiation and $10^{3.3}$ clonogenic cells surviving a comparable dose of X-rays. Neutron-irradiated cells repaired less sublethal injury than X-ray-irradiated cells. However, the repair observed between doses of 14 MeV neutrons was greater than repairs observed with neutron-irradiation at lower energies.

- 0525 PATHOGENESIS OF RADIATION-INDUCED DYSPLASIA. (E.) Shively, J. N. (Col. Vet. Med. Biol. Sci., Colorado St. U., Fort Collins), R. D. Phemister, G. P. Epling and R. Jensen. *Invest Ophthalmol* 9(11):888-900, 1970.

The response of the developing retina of 2-day-old beagle dogs to γ-irradiation (170 r) and the pathogenesis of associated retinal dysplasia were followed with light and electron microscopic observation over periods ranging from 1 hr to 180 days postirradiation. One hr after irradiation an onset of degenerating and pyknotic cells were observed in the vitreal part of the neuroblastic layer and

the inner nuclear layer; after 12 hr 10-20% of the cells had become pyknotic. After 1 and 2 days necrosis was more widespread in the posterior section of the retina and ectopic cells were seen, while after 4 days necrosis became less prominent until after 8-10 days postirradiation dysplasia was evident. The most conspicuous manifestations of the dysplasia (rosettes, tubules, and nests of ectopic photoreceptor cells) persisted for 180 days when atrophy of the dysplastic areas was noted.

0526 INCORPORATION OF ^{14}C - AND ^3H -THYMIDINE IN LYMPHOCYTES AFTER EXTRACORPOREAL IRRADIATION OF THE BLOOD. (E.) Rosengren, B. (Sahlgrenska sp., Goteborg, Sweden), S. E. Bergentz, K. Nordahl-Kiessling, L. Lindholm and B. Persson. *Rev Trop Etud Clin Biol* 15(7):778-782, 1970.

The effect of extracorporeal irradiation on the capacity of human lymphocytes to synthesize DNA following phytohemagglutinin stimulation or allogenic lymphocyte stimulation was investigated. Blood samples were collected from patients after extracorporeal radiation of the blood via an arteriovenous shunt dialysis tubing (multiple doses totaling 12,000-40,000 rads), and cells were stimulated by the addition of phytohemagglutinin or allogenic cells to cultures. DNA synthesis was assayed by allowing the incorporation by the lymphocytes of ^3H -thymidine or ^{14}C -thymidine. Incorporation of ^3H -thymidine by phytohemagglutinin-stimulated cultures was reduced by irradiation; ^{14}C -thymidine activity was 1,800 cpm in 1 patient 16 hr after blood irradiation with 18,000 rads and 202 cpm 21 hr after 20,000 rads. Reduced capacity to incorporate ^3H -thymidine following irradiation without phytohemagglutinin stimulation was also noted in lymphocytes of patients whose capacity to incorporate the label was measured before and after treatment; in 1 such patient, thymidine incorporation before treatment with 4000 rads was measured to be 1.34×10^6 cpm and after treatment was 3.75×10^5 cpm. Reduction of label incorporation consequent to irradiation was especially evident immediately after irradiation; and variations in the response to irradiation among different patients may have been due to variations in the exchange between circulating and noncirculating lymphocytes.

0527 CHROMOSOME ABERRATIONS INDUCED BY AN ULTRASONIC FETAL PULSE DETECTOR. (E.) Macintosh, I. J. C. (Med. Sch., U. Cape Town, Union of South Africa) and D. A. Davey. *Brit Med J* 4(5727):1-93, 1970.

Vessels containing 5 ml of blood cultures from healthy humans were exposed to ultrasound produced by an ultrasonic fetal heart detector for periods of 1 and 2 hr; the culture in one vessel was permitted to form standing waves produced by ultrasound, but standing waves were suppressed by polyethylene membranes in the second culture vessel. The ultrasound treatment produced a marked and consistent rise in the number of blood culture cells with chromosomal aberrations; cells in the vessels

exposed to ultrasound for varying periods exhibited cell-aberration totals of 26, 50, and 22 aberrations/100 cells as compared to 5 aberrations/100 cells recorded for untreated controls. The vessel showing the highest number of aberrant cells/100 had been the one exposed to ultrasound for 2 hr and in which standing waves had been eliminated.

0528 LATE GASTRIC CARCINOMA DEVELOPING AFTER SURGERY FOR BENIGN CONDITIONS: ENDOSCOPIC AND HISTOLOGIC STUDIES OF THE ANASTOMOSIS AND DIAGNOSTIC PROBLEMS. (E.) Kirsner, J. B. (U. Chicago Dept. Med., Ill.), S. Kobayashi and J. C. Prolla. *Amer J Dig Dis* 15(10):905-912, 1970.

Seven patients who underwent surgery for benign gastroduodenal diseases (including duodenal and gastric ulcers) developed gastric carcinomas after a mean elapsed time of 23 yr since the original operation. Surgical operations performed included Billroth operations I and II and gastroenterostomy. In all 7 cases, the carcinomas involved the anastomotic area; gastroscopic biopsy demonstrated a high incidence of atrophic gastritis and frequent polypoid formation at or near the anastomotic site. More patients who underwent gastrojejunectomy than the Billroth I operation exhibited these changes. Although the frequent occurrence of gastric atrophy with intestinal metaplasia has suggested a close relationship between the development of carcinoma and anastomosis with gastroenterostomy, endoscopic and biopsy studies did not demonstrate progressive advancement of gastric atrophy.

0529 THYROID NEOPLASIA AS LATE EFFECT OF EXPOSURE TO RADIOACTIVE IODINE IN FALLOUT. (E.) Conard, R. A. (Brookhaven Natl. Lab., Upton, N.Y.), B. M. Dobyns and W. W. Sutow. *JAMA* 214(2):316-324, 1970.

The development of thyroid neoplasia in inhabitants of Rongelap Island, who were accidentally exposed to radioactive iodine as bomb-fallout in 1954 (doses of 69-175 rad) was investigated in yearly checkups. Thyroid abnormalities had developed in 21 of 67 of these people, 3 with malignant lesions, 16 with benign adenomatous nodules, and 2 with atrophy of the gland with hypothyroidism. The preponderance of lesions occurred in children exposed at less than 10 years of age who had received a greater thyroid exposure. Growth retardation associated with hypothyroid tendency was noted in some children who appear to be responding favorably to thyroid hormone medication. Apparently, exposure to radioactive iodine and exposure to x-irradiation carry approximately the same risk of thyroid cancer.

0530 THE MALIGNANCY OF MIXED TUMORS OF THE PAROTID GLAND: A CLINICOPATHOLOGICAL ANALYSIS OF 70 CASES. (E.) Saksela, E. (3rd Dept. Path., U. Helsinki, Finland), J. Tarkkanen and A. Kohonen. *Acta Otolaryng* 70(1):62-70, 1970.

Tumor tissue from 119 cases of parotid tumor was subjected to histopathological classification

related to the clinical history of the condition and to the findings of 5 yr follow-up data; tumors studied included benign "mixed tumor" (the most common finding, accounting for 64 of the 119 cases) and carcinoma in mixed tumor (6 cases). Only carcinoma in mixed tumor behaved in a malignant fashion and the rest of mixed tumors showed a benign course of disease. The number of recurrences was higher in the group of tumors with multiple nodules, and otherwise no differences in the behavior was noted as related to cellularity, cell atypism and mitotic frequency. Of the 6 patients with carcinoma in mixed tumor 3 had received irradiation therapy (3000-6000 rads) for a parotid tumor not surgically removed 8-24 yr prior to present rapid enlargement. None of the patients with equally long histories of benign mixed tumors had received irradiation treatment.

0531 MULTIPLE BASAL CELL CARCINOMAS ARISING IN RADIATED BURN SCARS: CASE REPORT. (E.)

Stone, N. H. (Chicago Med. Sch., Ill.) and M. M. Montiel. *Plast Reconstr Surg* 46(5):506-509, 1970.

The case of an Australian woman who was severely burned in childhood, and received protracted radiation therapy to relieve keloid formations developing on the burn scars is reported. Twenty-two yr later, the patient presented with multiple basal cell carcinomas on skin areas which had been both burned and irradiated, including abdomen, groins, lower thorax and anterior thighs. Only those areas which had been both burned and irradiated showed lesions, a feature of the case which may suggest that burns and irradiation acted as co-carcinogens.

0532 MALIGNANT TUMORS OF THE RAT ADRENAL GLAND INDUCED BY FISSION NEUTRON IRRADIATION. (E.)

Vogel, H. H., Jr. (Coll. Med., U. Tennessee, Memphis) and R. Zaldivar. *Int J Radiat Biol* 18(3):267-270, 1970.

Adrenal carcinomas were found in rats that were subjected to whole-body fission neutron irradiation when 6-10-wk-old; histological studies revealed that the neoplasms were cortical carcinomas and in 1 case pleomorphic sarcoma. Only 1.1% of the control rats not receiving irradiation developed such tumors compared to a 13.1% incidence in irradiated rats. The tumors showed cytological signs of malignancy and lacked a fibrous capsule surrounding the tumor; tumor-cell emboli were found in the blood vessels of affected rats, and metastasis to the intestine was observed. The pleomorphic sarcoma of the adrenal was a relatively large tumor exhibiting a considerable amount of necrosis and showing a variety of highly malignant cell-types. The radiation-induced tumors represented late radiation effects, with age at death ranging from 414-1311 days.

0533 RECOVERY FROM RADIATION INJURY WITH AND WITHOUT BONE MARROW TRANSPLANTATION: EFFECTS OF SPLENECTOMY. (E.)

Smith, L. H. (Oak Ridge Natl. Lab., Tenn.) and T. W. McKinley, Jr. *Radiat Res* 44(1):248-261, 1970.

The effect of lethal X-irradiation on splenectomized mice which had been injected with syngeneic bone marrow was investigated, in order to assess the importance of the spleen for recovery from radiation injury. Mice were splenectomized at different times before exposure to 650-950 rads of X-irradiation; bone marrow was usually injected 4 hr after irradiation. Splenectomy 2 days prior to irradiation of mice not injected with marrow cells improved the 30-day survival of irradiated mice, especially in the 750-850 rad range, with 95% of splenectomized mice surviving 750 rads, and 50% of intact mice surviving the same dose. The protective effect of splenectomy performed 2 days before irradiation was higher (71% survival) than the protective effect of splenectomy performed 30 days before irradiation (44% survival). Injection of bone marrow in splenectomized and unsplenectomized mice had the effect of equalizing 30-day survival rates for both groups of animals. Splenectomy performed after irradiation reduced survival, and survival varied inversely with the interval between marrow injection and splenectomy. Ferrokinetic studies using ^{59}Fe indicated that in lethally irradiated mice injected with marrow cells early regenerative erythropoiesis was reduced in those animals splenectomized prior to irradiation but only when the dose of marrow cells was limiting. Apparently, the spleen contributes to the early restoration of a hematopoietic compartment least critical to the survival of the animal; whatever contribution the spleen makes to survival is compensated for by other tissues when the spleen is absent. Splenectomy 2 days before irradiation increased the irradiation $\text{LD}_{50/30}$ by approximately 65 rads, a protective effect which remains unclear.

0534 BONE MARROW AND SPLEEN INTERRELATION IN LOCAL IRRADIATION: DATA OF CYTOMETRY

Fe^{59} INCORPORATION. (E.) Kabakov, Y. N. (USSR Acad. Med. Sci., Obninsk) and K. A. Folanova. *Folia Haemat* 94(1):64-73, 1970.

Cytometric studies and studies of Fe^{59} incorporation were performed on lymphocytes from irradiated bone marrow and spleen of rats. Lymphocytes from the spleen of rats which had been exposed to 1000 rads of X-irradiation were subjected to cytometric measurement, and Fe^{59} incorporation by cells of locally irradiated and screened bone marrow was terminated in a separate group of animals. Cytometric examination from 0-10 days after irradiation showed that lymphocytes of the spleen, locally irradiated and screened bone marrow had diameters of 6-15 μm with 9 μm being the prevailing size in both spleen and bone marrow. Numbers of small lymphocytes (diameters less than 9 μm) decreased significantly (50% decrease) coincidentally with the intensive restoration of erythropoiesis in the locally irradiated region and with the increase in numbers of normoblasts. Fe^{59} incorporation also showed a negative correlation with recovery of irradiated bone marrow and with restored stability of erythropoiesis in screened bone marrow. Immediately prior to recovery of locally irradiated bone marrow, a significant decrease in the distribution of spleen

lymphocytes was noted. Apparently, small lymphocytes may participate in the recovery of irradiated bone marrow as precursor cells capable of accelerated transformation into normoblasts.

- 0535 OSTEOSARCOMA AND PAROSTEAL SARCOMA OF THE MAXILLA AND MANDIBLE: STUDY OF 20 CASES. (E.) Roca, A. N. (U. Texas Med. Branch, Galveston), L. Smith, Jr. and B. S. Jing. *Amer J Clin Path* 44(4):625-636, 1970.

The pathology and incidence of osteosarcoma and parosteal sarcoma of the maxilla and mandible were studied in a series of 20 cases. Nine tumors were located on the maxilla, 11 on the mandible. The average age of patients with maxillary sarcoma was 35.6 yr, and the average age of patients with mandibular sarcoma was 50.4 yr. The patients comprised 13 men and 7 women; 15 patients were Caucasian. None of the patients had a previous history of trauma, Paget's disease or benign bone tumors, although 2 osteosarcomas arose in patients who had been irradiated. The average age of onset for osteosarcoma of the jaw was 1 or 2 decades later, than the average age of onset for osteosarcomas of other regions. Gross features of parosteal osteosarcoma included a regular external surface without a cartilaginous cap. Tumors were primarily composed of intermixed bone and fibrous and cartilaginous tissue. Microscopically, tumors showed abundant calcification and anaplastic osteoblasts with proliferation of malignant osteoblasts and osteoid production. Osteosarcomas exhibited a greater tendency to metastasize than did parosteal osteogenic sarcoma.

- 0536 ACTION SPECTRUM OF ULTRAVIOLET LIGHT-INDUCED DAMAGE TO NUCLEAR DNA *IN VIVO*. (E.) Tan, E. M. (Scripps Clin., Res. Found., La Jolla, Calif.), R. G. Freeman and R. B. Stoughton. *J Invest Derm* 55(6):439-443, 1970.

The range of UV radiation capable of inducing damage *in vivo* to DNA in the epidermis of hairless mice was determined using an indirect immunofluorescent technique with antiserum against UV-irradiated DNA. UV radiation from 254 nm to 300 nm was effective in producing damaged DNA at energy levels (88-140 millijoules/cm²) comparable to 10 MED (human minimal erythema dose). At 305 nm 10 MED was sufficient to produce photochemical lesions, but they were not as extensive as those produced at the shorter wavelengths. At 310 and 320 nm, 7,200 millijoules/cm² of energy was required to produce the nuclear lesions, while at 330 nm no lesions were evident even with this high energy.

- 0537 THE METABOLISM OF ISOLATED PERFUSED RAT LIVER FOLLOWING *IN VITRO* RADIATION. (Ger.) Stähler, F. (Inst. Biophys. Radiobiol., U. Hamburg, Germany) and I. Sinn. *Strahlentherapie* 140(2):213-220, 1970.

Changes in the content of free amino acids in rat liver following irradiation with X-rays were inves-

tigated in order to determine the role of the liver as a regulating organ in this context. The liver, isolated from healthy rats, was perfused with plasma with washed beef erythrocytes as oxygen carriers, and various amino acids as substrates. The irradiation doses were 1000 or 5000 rads (200 kV X-rays), and the amino acid content of the cytoplasm and of the perfusion fluid was followed for 3 hr. An altered amino acid metabolism in the *in vitro* preparation resulted following irradiation, but liver metabolism following whole body irradiation was relatively unchanged. The perfused liver changes were partly dose dependent; utilization of the incorporated amino acids following radiation at 1000 rad was increased, but this was decreased at the 5000 rad level, and on prolonged perfusion these values became equal. The intracellular amino acid content following 1000 rad was reduced. Tryptophan and arginine incorporation was decreased, and threonine elimination and taurine synthesis were stimulated. The mean quotient of the intra/extracellular amino acid content, which is directly related to the active transport of amino acids through the cell membrane, appeared to decrease with the irradiation dose.

- 0538 LONG-TERM CYTOGENETIC AND CLINICAL CONTROL OF A CHILD FOLLOWING INTRAUTERINE IRRADIATION. (E.) Kucerova, M. (Postgrad. Med. Inst., Prague, Czechoslovakia). *Acta Radiol* 9(4):353-361, 1970.

Cytogenetic studies were performed on a 4-yr-old child who had been exposed to roentgen irradiation *in utero* when its mother underwent radiation therapy (total of 3580 r) for cervical cancer. The child, a girl, exhibited mental retardation, microcephaly, and slight anemia and leucocytosis. Cytogenetically, the patient revealed a significant increase of mitoses with chromosome aberrations, the percentage of aberrant mitoses in the blood increasing from 6.6% in the first post-irradiation yr to 20% in the third postirradiation yr; a sharp increase in aberrant mitoses following irradiation had also been noticed in the mother (deceased at the time of the report). Both mother and child had increased incidence of monotrismy (an increase from 2% to 5.40% in the child in 4 yr) following irradiation exposure as well as increased chromosome breaks (an increase from 1.5% to 4.1% in 4 yr).

- 0539 RELATIVE BIOLOGICAL EFFECTIVENESS OF HEAVY IONS IN PRODUCING MUTATIONS, TUMORS, AND GROWTH INHIBITION IN THE CRUCIFER PLANT, *ARABIDOPSIS*. (E.) Hirono, Y. (Biol. Res. Lab., Nippon Soda Co., Kanagawa, Japan), H. H. Smith, J. T. Lyman, *Radiat Res* 44(1):204-223, 1970.

A heavy-ion linear accelerator was used to bombard dry seeds of the crucifer plant, *Arabidopsis thaliana* with ¹²C, ⁴He, ⁷Li, ¹⁶O, ²⁰Ne and ⁴⁰Ar ions in order to investigate the effectiveness of heavy ions in producing mutations, tumors and growth inhibition in the mature plants. The lowest dose of heavy ion

irradiation which produced tumors in 63% of plants was 4.8 kilorads for ^7Li ions; the highest dose of X-rays producing 63% tumor-bearing plants was 159 kilorads. Evaluation of the relative biological effectiveness (RBE) of irradiation with various ions for producing tumors indicated that ^7Li ions have the highest RBE of the ions tested. For growth inhibition and mutation, as well as for tumor development, the RBE of the various ions showed the same pattern consistently; at radiation doses of 18 KeV/ μ , the RBE was low, and at 72-174 KeV/ μ the RBE was maximal. Application of track segment analysis indicates that sensitive sites are multiple in number or complex in structure with effective thickness of a few Å to a few tens of Å, which approximates molecular bond distances as in DNA.

- 0540 CHILDHOOD CANCER IN RELATION TO PRENATAL EXPOSURE TO ATOMIC BOMB RADIATION. (E.) Jablon, S. (Japanese Natl. Inst. Hlth., Hiroshima) and H. Kato. *Lancet* 2(7681):1000-1003, 1970.

An examination of childhood cancer incidence among 1292 children exposed prenatally to radiation from nuclear bomb blasts in Hiroshima and Nagasaki, Japan, revealed that during the first 10 yr of life in the children studied only 1 died of leukemia, indicating that radiation exposure produced no significant excess in mortality in this population. These findings showed that the "extra" deaths produced/1 million person-rads of radiation numbered 5.2, a figure which appears to conflict with the estimate of 572 extra deaths/1 million person-rads produced by fetal irradiation in a study by Stewart and Kneale. The explanation of the divergence of these results is obscure; it may be that in Stewart and Kneale's study the population examined (children of women undergoing pelvic irradiation during pregnancy for medical reasons) was at an unusually high risk of developing cancer for reasons other than fetal irradiation.

- 0541 SMALLER G CHROMOSOMES IN THE BONE-MARROW CELLS OF HEAVILY IRRADIATED ATOMIC-BOMB SURVIVORS. (E.) Kamada, N. (Res. Inst. Nucl. Med. Biol., Hiroshima, Japan), T. Tsuchimoto and H. Uchino. *Lancet* 2(7678):880-881, 1970.

Seventy-four survivors of the atomic bomb explosions in Japan in 1945 were examined to observe the incidence of chromosomal aberrations in the bone marrow in this population. Four of 13 people who had been from 0-1000 m from the hypocenter of the explosions had a total of 7 types of stable chromosome abnormality; aberrations included smaller G chromosomes morphologically similar to the Philadelphia chromosome in chronic myelocytic leukemia. None of those who had been more than 1000 m had chromosome abnormalities. The 4 subjects with smaller G chromosomes all experienced moderate or severe radiation sickness after the explosion, but none had any evidence of leukemia. The cells with smaller G chromosomes appear to constitute a clone in the bone marrow of these survivors; the percentage of the small G chromosome phenomenon in this population was 10.9.

- 0542 EFFECT OF RADIATION ON LECITHIN METABOLISM, SURFACE ACTIVITY, AND COMPLIANCE OF RAT LUNG. (E.) Naimark, A. (Fac. Med., U. Manitoba, Winnipeg, Canada), D. Newman and D. H. Bowden. *Canad J Physiol Pharmacol* 48(10):685-694, 1970.

Lecithin metabolism and surface properties of the lungs of rats irradiated with ionizing radiation were investigated. Two-month-old rats received single doses of 3000 rads of roentgen radiation in the right hemithorax, 1-4 months after which exposed lungs were compared with contralateral shielded lungs, and with the lungs of non-irradiated controls. Four months after exposure, irradiated lungs did not differ in DNA content from controls but exhibited decreased lecithin content (8.0 mg/g fresh wt for controls vs 6.9 mg/g in treated animals), depressed incorporation of palmitate- ^{14}C into lecithin *in vitro* (8.25×10^3 cpm/mg for controls vs 5.1×10^3 cpm/mg for irradiated rats), a decrease in the percentage of palmitic acid in the lecithin fraction (60% for controls vs 51% for irradiated animals). Changes in other phospholipids were qualitatively similar. The stability of bubbles expressed from the cut surface of irradiated lungs decreased progressively with time, indicating impaired surface activity of the lung-lining layer. This was associated with a progressive decrease in compliance of the lung. Electron microscopy revealed no qualitative changes in the alveolar epithelial cells. Morphologic evidence of injury was most prominent in the capillaries and could be detected before changes in phospholipid content, surface activity, and compliance; these changes consisted of swollen basement membranes, cytoplasmic vacuolation of the endothelial cells and occasional aggregates of platelets in the vessels. These findings appear to indicate that the changes in lecithin content and surface activity produced by irradiation of the lung were secondary to endothelial damage.

- 0543 RADIATION-INDUCED OSTEOSARCOMA IN THE RAT AS A MODEL FOR OSTEOSARCOMA IN MAN. (E.) Cobb, L. M. (Roy. Cancer Hosp., London, England). *Brit J Cancer* 24(2):294-299, 1970.

The pathology of experimentally-induced osteosarcoma (insertion of ^{32}P -impregnated polyvinyl chloride discs into the distal femoral metaphysis) in female Chester Beatty random-bred rats was compared with that of the spontaneous osteosarcoma in man. Discs with a surface dose rate of 27.6 r/min in tissue equivalent material produced osteosarcoma in 26 (28%) 6-14 months after implantation, and discs with a surface dose rate of 3.6 r/min caused the tumor in 1 rat (1%) 8 months after implantation. The tumors were identified by palpation at diameters of 1.5-2 cm and grew to 5-7 cm within 8 wk causing impairment of the animals' movements. Histopathologically the tumor in the rat is similar to osteosarcomata in man except that well-differentiated malignant osteoblasts predominate in the rat while cellular pleomorphism is found in man. Repeated transplantation of the rat osteosarcomata produced this cellular pleomorphism commonly seen in man.

- 0544 HORMONE-MEDIATED CHANGES OF LIVER POLY-RIBOSOMES IN IRRADIATED RATS. (E.)
 aeysens, W. (Ctr. Study Nucl. Energy, Mol, Belgium),
 Goutier and V. Vangheel. *Strahlentherapie* 140(2):
 04-212, 1970.

Liver polyribosomes in X-irradiated rats (500-2000 r) were compared (*in vitro* synthetic activity) with those of non-irradiated animals and the role of hormones in the mechanism for polyribosome modification was examined. In the presence of optimal amounts of cell sap (polysomal protein to cell sap protein ratio of 1:20) irradiated polysomes (500 r) incorporated more ^{14}C -phenylalanine than control polysomes; the increase in amino acid incorporation was proportional to the amount of irradiated polysomes used. Increasing the doses of irradiation increased the difference in incorporation between the irradiated group and the controls to over 30% after 1000 or 2000 r. Polyuridylic acid stimulated ^{14}C -phenylalanine uptake in polysomes from irradiated livers less (115%) than in polysomes from normal livers (175%). Local irradiation of the liver did not affect polysome distribution (sucrose density gradient), but whole-body irradiation with shielded liver shifted polysomes to heavier aggregates, and ACTH (10-12 U/100 g) produced a similar effect. Bilateral adrenalectomy did not interfere with the radiation-induced shift, but this negative result was due to the presence of accessory adrenal tissues in Wistar rats. The shift to a higher proportion of heavy polysomes may be a late result of the first stress reaction and may occur through stimulation of the hypothalamus-pituitary-adrenal axis.

- 0545 INDUCED CELL PROLIFERATION AND THE INITIATION OF SKIN TUMOR FORMATION IN MICE BY ULTRAVIOLET LIGHT. (E.) Pound, A. W. (Dept. Path., U. Queensland, Australia). *Pathology* 2(4): 269-275, 1970.

Initiation of skin tumor formation in white mice by a single short exposure (60 sec) to ultraviolet UV light was studied with UV exposure alone, UV exposure plus painting the skin with a promoting agent (croton oil) after exposure, and with painting the skin with an irritant chemical (croton oil, acetic acid, or xylene) prior to UV exposure. No tumors developed in animals exposed to UV light with no pretreatment or after treatment with irritant chemicals alone; mice pretreated with croton oil, acetic acid, or xylene before UV exposure and painted with croton oil after exposure developed tumors (no. tumors/no. mice; 12/23, 9/20 and 9/16, resp.). Mice exposed to UV light and painted with croton oil after exposure and mice painted with croton oil without UV exposure developed tumors (7/23 and 5/24). Mice pretreated with acetic acid or xylene and then promoted with croton oil without UV exposure also developed tumors (2/21 and 4/28, resp.).

- 0546 CORRELATION OF RADIATION-INDUCED ULTRA-STRUCTURAL CHANGES IN MOUSE HEPATOCYTES WITH ALTERATIONS IN PLASMA CONCENTRATION OF PROTEIN-BOUND NEUTRAL HEXOSES. (E.) Rene, A. A. (Armed

Forces Radiobiol. Res. Inst., Bethesda, Md.) and A. S. Evans. *Radiat Res* 44(1):224-236, 1970.

Liver cell abnormalities induced by whole-body irradiation, and the correlation of these abnormalities with changes in plasma concentration of glycoproteins, were investigated in young adult male mice. Whole body doses of 530 rads of mixed γ -ray-neutron irradiation were administered to rats at rates of 20 rads/min. Although irradiation did not affect the flood concentration of protein-bound carbohydrates (neutral hexoses) in mice which survived the irradiation, concentrations increased from 1.8-2.2-fold in mice which died following irradiation. Electron microscopic examination of the cytoplasmic organelles in hepatocytes of irradiated moribund mice, mice surviving irradiation, and fed and starved unirradiated controls, showed that among the radiation-induced differences were moderate to marked dilatation of the rough endoplasmic reticulum, increased Golgi activity, and rounding of the mitochondria with a decrease in numbers of mitochondrial granules. A correlation between ultrastructural cellular alterations and changed concentrations of protein-bound neutral hexoses was evident.

- 0547 IRRADIATION AS AN ETIOLOGIC FACTOR IN THE DEVELOPMENT OF MELANOMA. (E.) Conley, J. (St. Vincent's Hosp., New York, N.Y.). *Arch Otolaryng* 92(6):627-631, 1970.

Five cases of melanoma involving the lip, cheek and neck, in which radiation therapy appeared to be a causal factor, are described. Patients were of both sexes, and ranged in age from 34-78 yr; radiation therapy had been used for various conditions, including scars, papillomas, and squamous cell cancer of the lower lip. The periods between exposure to therapeutic radiation and onset of melanoma were 40, 6, 5, and 1 yr, and 4 mo. A clear causal relationship between radiation and melanoma was suggested in the cases of short latency, and in cases where melanoma developed at the precise site of radiation treatment. All but 1 of the patients died of their conditions.

- 0548 THE FINE STRUCTURE OF OSTEOSARCOMA PRODUCED EXPERIMENTALLY IN RATS. (E.) Cameron, D. A. (Dept. Path., U. Sydney, Australia). *Pathology* 2(3):223-230, 1970.

White rats received i.p. injections of $1.0 \mu\text{C/g}$ ^{32}P , and thereafter received $0.6 \mu\text{C/g}$ ^{32}P at 2, 4, 6, and 8 wk of age; the fine structure of the osteosarcomata induced by ^{32}P was examined. Twenty tumors were found in the long bones of 16 rats, the period from the last injection to the observation of the first tumor being 32 wk. Most tumors were found in the proximal ends of the tibiae, and in 6 rats metastases were found in the lungs. The fine structure of most of the component cells showed relatively inconspicuous Golgi zones, limited endoplasmic reticulum and few mitochondria; it seemed

PHYSICAL CARCINOGENESIS

unlikely that these cells played much part in matrix synthesis. Other cells more closely resembled osteoblasts, and they were probably derived from the more primitive tumor cells rather than directly from the original bone cells. Presumably they secreted the matrix component of the hard tissue of the tumors. This matrix did not appear to be neoplastic, and its fine structure resembled that of fracture callus. Cells were included within the matrix and were analogous to osteocytes although some of the superficial ones had features of the undifferentiated cells. The few multinucleated cells present resembled osteoblasts, although most of them seemed to be non-functioning and lacked a brush border. Normal endothelial cells lined the thin-walled blood vessels which traversed the tumors.

0549 LONG-TERM RESULTS OF TREATMENT OF THYROTOXICOSIS IN CHILDREN AND ADOLESCENTS WITH RADIOACTIVE IODINE. (E.) Hayes, A. (Harvard Med. Sch., Boston, Mass.), E. M. Chapman and J. D. Crawford. *New Eng J Med* 283(18):949-953, 1970.

The possibility that radioiodine treatment for thyrotoxicosis predisposed patients to cancer either locally in the thyroid or as leukemia was investigated. Thirty patients aged between 8-18 yr were treated with ^{130}I (2 patients) or ^{131}I (28 patients) in doses of from 2-32 mC of ^{131}I for thyrotoxicosis. The average dose/patient was 6.6 mC and the mean length of patient follow-up observation was 9.2 yr. No deaths and no evidence of cancer or leukemia were seen in this series of patients. Prompt remission of the disease was obtained with a single dose in 25 cases. Permanent hypothyroidism developed in 8 patients. Recurrence of thyrotoxicosis associated with benign nodular hyperplasia was observed in 1 case 17 yr after treatment with ^{130}I . Twelve of the females treated with ^{131}I subsequently gave birth to 18 healthy children. One female treated with ^{130}I had an abnormal reproductive history.

VIRAL CARCINOGENESIS

0 COMPARATIVE STUDY OF THE MORPHOLOGY AND DISTRIBUTION OF VIRUS PARTICLES CAUSING LEUKEMIA AND LYMPHOSARCOMA IN MICE, RATS, CATS, AND GUINEA PIGS. (E.) Gross, L. (VA Hosp., Bronx, N.Y.) and D. G. Feldman. *Arch Geschwulstforsch* 1(1):1-9, 1970.

Issues of mice, rats, cats and guinea pigs with leukemia or lymphosarcoma were examined under the electron microscope to compare the morphology and distribution of virus particles in tissues of affected animals. Immature virus particles in leukemic mice were doughnut-shaped with 3 concentric shells and electron-lucent centers; they averaged 100 mμ in diameter and were found in the extracellular spaces and in the cytoplasm of cells. Mature virus particles had nucleoids and were larger than the immature particles, averaging 105 mμ in diameter. Cylindrical and filamentous structures were also found in leukemic mice, usually in the megakaryocytes in the spleen and bone marrow. More particles were found in mice having virally-induced leukemia than in mice with spontaneous leukemia. Virus particles in rat leukemia and lymphosarcoma were structurally similar to those in mice, but rather larger (average diameter, 99 mμ). Spherical virus particles occurred in leukemic cats which were morphologically like the C-type particles found in mice. In cats, particles were found budding from cell membranes; their average diameter was 100-115 mμ.

Leukemic guinea pigs harbored spherical, doughnut-shaped virus particles with electron-lucent centers; particles had nucleoids and were found in perinuclear cisternae in the spleen, lymph nodes, and bone marrow. Guinea pig particles seemed to bud from membranes of the endoplasmic reticulum. Mouse, rat, and cat leukemia virus particles were generally present in larger numbers than in guinea pig virus particles.

1 ENVELOPE ANTIGEN RELATIONSHIPS AMONG THREE HAMSTER-SPECIFIC SARCOMA VIRUSES AND A HAMSTER-SPECIFIC HELPER VIRUS. (E.) Kelloff, G. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), R. Huebner, N. H. Chang, Y. K. Lee and R. V. Gilden. *Int J Cancer* 9(1):19-26, 1970.

Hamster embryo fibroblasts were inoculated with dilutions of one of 3 hamster-specific sarcoma viruses [m-MSV(GLV)(O-H), m-MSV(O-H) or ki-MSV(O-H)] or non-sarcomagenic virus (HaLV), and interference tests were conducted by infecting the resulting cultures with 50-70 focus-forming units of virus; antisera neutralization tests were also performed. The purpose was to determine the immunological relationships among the 4 virus types. The 4 viruses shared at least 1 envelope antigen responsible for neutralization reactions. Specific interference for the sarcoma viruses was obtained in cultures infected with non-sarcomagenic virus. The tested viruses were easily distinguishable from murine C-type viruses in neutralization assays.

2 IMMUNOLOGICAL IDENTITY OF THE GROUP-SPECIFIC ANTIGEN OF HAMSTER-SPECIFIC C-TYPE VIRUSES AND AN INDIGENOUS HAMSTER VIRUS. (E.) Kelloff,

G. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), R. J. Huebner, S. Oroszlan, R. Toni and R. V. Gilden. *J Gen Virol* 9(1):27-33, 1970.

Hamster-specific C-type viruses from chronically infected tissue cultures were used as a source of hamster-specific group specific antigen, which was purified from the infected culture supernatant after being disrupted by ether extraction; the antigen was injected in guinea pigs for the purpose of preparing antisera against it, and the antisera was subjected to immunodiffusion and complement-fixation tests. Reactions of identity were obtained in immunodiffusion tests between all virus preparations while no reactions were obtained with uninfected cells and murine C-type virus preparations. Guinea-pig antiserum to the murine C-type virus group specific antigen did not react with any of the hamster virus preparations. This pattern of specificity was maintained in complement-fixation tests. The hamster-specific sarcoma viruses originally recovered from hamster tumors induced by murine sarcoma viruses, are considered to be pseudotype sarcoma viruses possessing the antigens of the indigenous hamster C-type virus and the sarcoma gene(s) of the original tumor inducing murine viruses.

0553 SYNTHETIC DNA-RNA HYBRIDS AND RNA-RNA DUPLEXES AS TEMPLATES FOR THE POLYMERASES OF THE ONCOGENIC RNA VIRUSES. (E.) Spiegelman, S. (Inst. Cancer Res., Columbia U., New York, N.Y.), A. Burny, M. R. Das, J. Keydar, J. Schlom, M. Travnick and K. Watson. *Nature* 228(5270):430-432, 1970.

Polymerase activity of 6 oncogenic RNA viruses was studied by using synthetic polynucleotides as templates. Analysis of the responses of avian myeloblastosis virus (AMV), feline leukemia virus (FLV), Moloney sarcoma virus (MSV), Rauscher leukemia virus (RLV), mouse mammary tumor virus (MTV), and a rat mammary tumor virus (RMTV) to resident RNA templates, to exogenous DNA (from trypsinized chick embryo cells), and to a synthetic hybrid duplex (dC·rG) indicated that the hybrid directed DNA synthesis ranged from 12 times to 351 times higher than the RNA or DNA directed syntheses. Among the ribohomopolymers, only rC possessed detectable template activity (pmoles nucleotide incorporated/5 min/10 μg viral protein) for AMV-polymerase (3.8), and among deoxyribopolymers, poly dC (11.0), poly dA (1.2), and poly dI (1.2) showed template activity. Except for rC·rG, all the synthetic double-stranded RNA and DNA homopolymers stimulated some incorporation of the complementary nucleotide pairs (the polyribopolymers appeared more effective than the corresponding deoxypolymers except for rC·rG). Some of the synthetic DNA-RNA hybrid duplexes, particularly dC·rG and dI·rC (141.0 and 104.6, resp.), were the most effective templates studied.

0554 NUCLEIC ACIDS-HYBRIDIZATION STUDIES IN NORMAL AND CANCER CELLS. (E.) Valladares, Y. (Natl. Inst. Oncol., City U. Madrid, Spain), Y. Alvarez, E. Tabares and T. Pintado. *Europ J Cancer* 6(9):335-347, 1970.

Hybridization of nucleic acids from normal and cancer cells (agar column technique of Bolton and McCarthy) were investigated. The specificity of DNA-DNA hybridization was demonstrated by the complete complementarity within AV3/INO DNA and salmon-sperm DNA and the complete complementarity within AV3/INO. Complementarity of AV3/INO-human amnion cell DNA and mRNA (with isogenic DNA) reached 89% for DNA-thymidine-³H and 45.5% for mRNA-³²P; after the DNA-mRNA hybridization (44.5%) the DNA still had binding sites for sRNA (9%) and for rRNA (0.6%). Normal mouse embryo DNA with itself showed 90% complementation and cancer virus-induced mouse tumor DNA with itself showed 87% complementation, while mouse embryo DNA confronted with mouse embryo mRNA resulted in 47.2% complementation and confronted with cancer virus-induced mRNA resulted in 37.7% complementation; cancer virus-induced tumor DNA confronted with the virus-induced tumor mRNA or normal embryo mRNA resulted in 46.5% and 31.2% complementation, resp. In the various virus-cell nucleic acids systems studied, part of cancer virus-DNA hybridized with 41,000 parts of cancer virus-induced mouse tumor DNA, 111,000 parts of normal mouse DNA, 399,400 parts of normal hamster DNA, 2340 parts of TC-CV/INO cell DNA, 99,000 parts of TC-SV40/INO cell DNA, or 500,000 parts of normal human amnion DNA.

0555 DNA POLYMERASE ACTIVITY ASSOCIATED WITH RNA TUMOR VIRUSES. (E.) Hatanaka, M. (Flow Lab., Rockville, Md.), R. J. Huebner and R. V. Gilden. *Proc Nat Acad Sci* 67(1):143-147, 1970.

Suspensions of murine leukemia virus, feline sarcoma virus, hamster helper-virus, feline leukemia virus, and viper C-type virus were incubated with a reaction mixture suitable for assay of DNA polymerase activity. Some virus preparations were shaken with ether for 10 min. before incubation. All of the viruses tested stimulated the incorporation of tritiated thymidine triphosphate (³H-TTP) into acid-insoluble material, with the viper virus preparation showing the highest incorporation activity rate (12,825 acid-insoluble cpm); enzyme activity was dependent on the presence of all 4 deoxyribonucleoside triphosphates. Treatment with ether increased DNA polymerase activity with all C-type virus preparations. Ether treatment also prolonged the time of intense DNA polymerase activity, which reached a plateau after 1 hr in untreated preparations and after 2 hr in ether-treated preparations. In ether-treated preparations and untreated preparations, DNA extracted from the reactions sedimented at 2-4S. Some 15-20% of the newly synthesized DNA remained associated with the virions until subjected to SDS-phenol extraction when intact virus was the template, but the DNA synthesized by the ether-treated virus preparations had no firm association with the whole virions and sedimented to the same position in sucrose gradients before and after SDS-phenol extraction.

0556 CELLULAR SURFACE CHANGES INDUCED BY ONCOGENIC VIRUSES AND THEIR ROLE IN MALIGNANT TRANSFORMATION. (Fr.) Montagnier, L. (Fac. Sci. Orsay, France). *Bull Cancer* 57(1):13-22, 1970.

Hamster (BHK 21/13 strain) fibroblasts cultivated on agar nutrient media were used to define stages of Rous or polyoma virus-induced transformation. Cell growth during transformation stage 1a was inhibited by dextran sulfate and promoted by insulin and collagen; cells able to develop without the addition of insulin and collagen and whose growth was less sensitive to dextran sulfate were classified as transformation stage 1b. Transformation stage 2 was characterized by cell growth on agar gel in the presence of dextran sulfate and AMP; lack of growth resulted in inhibition of cell growth by minimal amounts of dextran sulfate in the case of Rous Stage 2b of transformation with polyoma virus. Stage 2 consisted of cell growth capability in the presence of dextran sulfate with no exogenous AMP required. Transition from stage 1 to stage 2 of transformation required increased amounts of exogenous serum. Surface alterations in terms of dye absorbing capacity (ruthenium red) presented thin dye absorbing layers in stage 1a and 1b; these layers were absent in stage 2 and were dependent on the presence of purine nucleotides. Enzyme activity (phosphatase C) in the presence of bivalent ions on specific surface constituents suggested that lecithin phospholipid polar groups of the plasma membrane were being protected by a superficial constituent whose biosynthesis requires exogenous purine nucleotides.

0557 DNA SYNTHESIS BY RNA-CONTAINING TUMOR VIRUSES. (E.) Scolnick, E. M. (National Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), Aaronson and G. J. Todaro. *Proc Nat Acad Sci* 67(1):1034-1041, 1970.

The occurrence of an RNA-dependent DNA polymerase and some characteristics of the polymerase reaction (kinetics, sedimentation, and activity) were studied in oncogenic and non-oncogenic RNA viruses. The *in vitro* DNA polymerase required the 4 essential deoxyribonucleoside triphosphates; the reaction was dependent on temperature (optimal activity at 37°C), and optimal DNA synthesis occurred with Triton X-100 concentration at 0.010-0.03%. Rauscher leukemia virus and Moloney leukemia virus. In a sucrose gradient virion, enzymatic activity and the DNA product that was synthesized cosedimented, suggesting that the 3 are part of a complex. In the DNA polymerase assay, the incorporation (cpm) varied greatly among individual viruses with Rauscher leukemia virus the most active (64,000 compared to its control 430 with only the 4 essential nucleotides in the reaction). Other viruses showing activity were Moloney leukemia virus (5,900 compared to its control 401), Rauscher leukemia virus grown in human cells (2,000 compared to its control 295), Kirsten sarcoma virus (1,050 compared to its control 100), and a mammary tumor virus (1,050 compared to its control 100). The non-oncogenic RNA viruses (Sendai, respiratory syncytial, Newcastle disease, lymphocytic choriomeningitis, and influenza viruses) were inactive.

0558 REVERSION OF VIRUS-TRANSFORMED CELLS TO NORMAL PHENOTYPE ACCOMPANIES RETENTION OF HYPERPLOIDY. (E.) Pollack, R. (New York U. Med. Sch.).

York), S. Wolman and A. Vogel. *Nature* 228(5275): 967-970, 1970.

chromosome number and growth control of virus-transformed mouse cell lines and their revertants were examined. The 4 established cell lines (3T3, 3T6, 3T3, and Py3T3) had similar chromosome modes (73, 74, and 70, resp.) although only 3T3 had growth control. Selected variants (F13T6, F1SV3T3, and Py3T3) exhibited increased chromosome numbers (5, 118, and a bimodal 60, 120, resp.), while the revertants (ReSV3T3 and RePy3T3) had chromosome numbers (72 and 65, resp.) close to those of the transformed parent lines. An increase in chromosome number accompanies reversion, and a decrease accompanies back reversion.

9 SEROLOGICAL STUDIES OF RAT VIRUSES IN RELATION TO TUMORS. (E.) Lum, G. S. (Dept. U. Cincinatti, O.). *Oncology* 24(5):335-343, 1970.

biological differences and differences in infectivity between 2 rat viruses, Kilham and Olivier's virus and the rat virus strain of Lum and Reiner (L-S) were investigated. Inhibition of agglutination in rat sera subjected to heating, potassium periodate and kaolin, the percentage of sera with antibodies against the viruses, and the susceptibility of rats to infection with the viruses were determined. Hemagglutination-inhibition tests in untreated sera of rats infected with the viruses were 5 and 6, resp., for rat virus and L-S virus at a 20-fold dilution of serum. These titers were not affected significantly by heating at 37°C, 56°C, or by potassium periodate treatment. Kaolin treatment, however, reduced the titers of hemagglutinin-inhibitors in all sera tested (titers of less than 1 in both rat virus- and L-S-virus infected sera at a 20-fold serum dilution, resp.). In kaolin-treated sera, serum neutralization titers were even higher than hemagglutination-inhibitor titers. Antibodies against the 2 viruses were found by hemagglutination-inhibition tests in 100% of Long-Evans strain rats, in 58% of Sprague-Dawley rats, in 25% of Wistar rats, and in 0% of Marshall rats. Seventy-eight percent of Wistar rats with either spontaneous adenomata, benign cysts, or X-ray induced tumors had antibodies against 1 or both viruses, whereas none of the sera from rats with transplanted tumors showed virus antibodies. Infectivity tests showed that antibody-free Marshall rats developed fatal infections when injected with rat virus, while L-S virus produced only 42% mortality after a longer elapsed time from injection.

10 CYTOPATHOGENIC AND TRANSFORMATIVE EFFECT OF INFECTIVE AND ONCOGENIC VIRUSES IN TISSUE CULTURE. (Rus.) Zhudina, A. I. (USSR Min. of Health, Leningrad), and O. K. Kuznetzov. *Voprosy* 16(7):47-59, 1970.

cytopathogenic and neoplastic alterations induced by infectious (vesicular stomatitis and smallpox vaccine) and oncogenic (Rous sarcoma) viruses were

compared in chick embryo cell monolayer cultures. Cell disintegration and loss of contact inhibition of motion and reproduction occurred 4 hr after infection with vesicular stomatitis virus, 1 day after smallpox vaccine and 2-12 days after Rous sarcoma virus inoculations, leading to the appearance of morphological transformation foci consisting of epithelioid (in the case of vesicular stomatitis virus) or round basophilic cells with Rous virus. These foci never reached large dimensions and degenerated 5-7 hr after infection with the vesicular stomatitis virus. The smallpox vaccine virus-induced transformation foci (morphologically intermediate between the other two) were larger and more numerous; their degeneration started 24 hr after infection. The Rous virus-induced foci were the largest and the most numerous and never degenerated. An increase in cell basophilia, an enlargement of cell nucleoli and the development of symplastic areas (this latter was more manifested in case of the smallpox vaccine virus) were a common response to all 3 viruses. Intensified mitotic activity with temporary (24 hr) cell proliferation occurred in the smallpox vaccine virus-induced transformation foci; such proliferation was unlimited in the case of Rous virus-induced transformation. The proliferation stage is most likely a forerunner of malignancy. Oncogenicity of the smallpox vaccine virus in newborn mice is reviewed.

0561 STUDIES ON FBJ VIRUS-INDUCED BONE TUMORS IN MICE. (E.) Yumoto, T. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston), W. E. Poel, T. Kodama and L. Dmochowski. *Texas Rep Biol Med* 28(1-2):145-165, 1970.

Newborn mice of strains ICR and BALB/c received i.p. injections of 0.1 ml dilute virus-induced bone tumor extract, and 8-wk-old GP strain mice were implanted s.c. with bone tumor mince induced in GP mice by tumor extract, to investigate histologically the tumorigenic activity of bone tumor-inducing virus in animals. Bone tumors of the spine, ribs and/or long bones developed in 7 of 12 GP mice; and 3 developed bone tumors. None of the BALB/c or ICR mice developed bone tumors. Transplantation of the induced bone tumors from GP mice was successful in other mice of the same origin. Comparative light and electron microscope studies carried out on the induced and transplanted bone tumors in GP and CF1 mice showed that the tumors induced in GP and CF1 mice, with few exceptions, were periosteal osteosarcomas and paraosteal tumors containing calcified and uncalcified osteoid and chondroid. Osteogenic, chondrogenic, fibrosarcomatous and undifferentiated round or spindle cell areas of proliferation were frequently observed in the same tumor, but osteolytic tumors were not seen. Budding, immature and mature type C virus particles were seen in all tumors as well as in non-tumorous organs of the tumor-bearing mice. Type C virus particles and budding from plasma membrane were seen in large numbers in long-term tissue cultures derived from the induced tumors of CF1 and GP mice. Close similarity in both

structure and virus particle content of the induced and transplanted tumors in CF1 and GP mice was found. A neoplastic response of multipotential mesenchymal cells to viral infection seems to be implicated in bone tumors induced in the present study.

- 0562 GROUP-SPECIFIC ANTIGEN EXPRESSION DURING EMBRYOGENESIS OF THE GENOME OF THE C-TYPE RNA TUMOR VIRUS: IMPLICATIONS FOR ONTOGENESIS AND ONCOGENESIS. (E.) Huebner, R. J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) G. J. Kelloff, P. S. Sarma, W. T. Lane, H. C. Turner, R. V. Gilden, S. Oroszlan, H. Meier, D. D. Myers and R. L. Peters. *Proc Nat Acad Sci* 67(1):366-376, 1970.

Mouse embryos under 12-14 days in term were tested for the presence of a group-specific antigen of the C-type RNA tumor virus; embryos of all strains tested revealed detectable titers of group-specific antigen in the liver, spleen or thymus. Younger, rather than older, embryos were likely to be antigen-positive, particularly in those strains which normally revealed little or no expression of the RNA genome postnatally. The antigens were found in embryos of low-leukemia strains, free of infectious virus. The genome of RNA tumor viruses without infectious virus expression may be vertically transmitted as part of the natural genetic apparatus of normal mouse cells. Since group-specific antigens have also been described in chick embryos and immunological tolerance to homologous group-specific antigens has been demonstrated in hamsters and cats as well as in mice and chickens, the hypothesis has been extended to include vertebrate cells in general. The high incidence and titers of the group-specific antigen suggest that the genes for RNA tumor virus may be important as gene determinants in the developing embryo, in addition to acting as determinants of carcinogenesis.

- 0563 MORPHOLOGICAL VARIATION OF A SYNCYTIAL VIRUS FROM LYMPHOSARCOMATOUS AND APPARENTLY NORMAL CATTLE. (E.) Boothe, A. D. (Natl. Anim. Dis. Lab., Ames, Iowa), M. J. Van Der Maaten and W. A. Malmquist. *Arch Ges Virusforsch* 31(3-4):373-384, 1970.

Bovine embryonic spleen cell cultures were infected with bovine syncytial virus which had been isolated from both normal cattle and cattle bearing lymphosarcomas, and infected cells were examined by electron microscopy. A double-membrane enveloped virus particle associated with the endoplasmic reticulum were found in the cytoplasm of the cells. These particles consisted of nucleocapsids measuring 35-45 mμ in diameter; 2 or more nucleocapsids were sometimes contained in the same membrane envelope. The endoplasmic-reticulum-associated viral particle had a nucleocapsid morphologically similar to that of bovine syncytial virus, and it was associated with bovine syncytial virus immunofluorescence. It occurred in the same cells and cell cultures as bovine syncytial virus, and it could not be demonstrated in cell cultures in the absence of bovine syncytial virus. On the basis of the 4 latter findings, it appears that the double membrane

enveloped, endoplasmic reticulum-associated viral particles observed were an aberrant form of bovine syncytial virus.

- 0564 INFLUENZA VIRUS AND LUNG CARCINOMA IN EXPERIMENTS. (Ger.) Staemmler, M. (Rechenberg Lab. Chem., Grunenthal GmbH., Stolberg, Germany), Foitzik and M. Heydenrich. *Z Krebsforsch* 74(3):283-294, 1970.

The effect of intranasal administration of influenza virus A, strain PR 8 in dilutions of 10^4 - 10^6 , in C57BL/6 mice was investigated. The first experimental group was infected with the virus under light ether anesthesia using a 0.1 ml suspension. The animals were dissected immediately after death and a suspension of lung tissue (with the adapted virus) was prepared for injection into another group of mice. Of the 323 animals infected, 136 died within the first 6 days; a second group of 248 mice received the virus administration without prior adaptation. Of the 571 animals thus treated, 248 survived the first 6 days, but most of the animals died within 20 days of the infection. Histological examination suggested the appearance of early changes in the alveoli predominantly of the squamous type, with the later ones showing the adenocarcinoma type cells.

- 0565 TRANSMISSION OF AN AMPHIBIAN LYMPHOSARCOMA TO AND THROUGH INSECTS. (E.) Nayar, K. K. (Dept. Zool., U. Kerala, Trivandrum, India), E. Arthur and M. Balls. *Oncology* 24(3):377, 1970.

Toads (*Xenopus laevis laevis*) were given implants of living or frozen lymphosarcoma, and extracted from the induced lymphosarcomas from spleen, liver, and kidney of the toads were implanted in cockroaches. The salivary glands of all of the toads which survived (163/174) were affected by aggregates of hemocytes. Fractions of the abnormal roach tissue which were then transferred to young mature *Xenopus* caused the development of lymphosarcomas in the toads in 30/57 cases. Infectivity appears to have been retained during passage through the insects, suggesting that insects can be used as reservoirs of infectivity for vertebrate lymphosarcomas.

- 0566 EVIDENCE FOR A DNA REPLICATIVE GENOME IN RNA-CONTAINING TUMOR VIRUSES. (E.) J. P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and A. V. Bader. *Proc Nat Acad Sci* 67(2):843-850, 1970.

The requirement for DNA synthesis in the replication of RNA tumor viruses (Rous sarcoma virus, avian leukosis virus) immediately after infection was studied in chick embryo cells using 5-bromodeoxyuridine (BrdU). Treatment of the cells with BrdU (100 μg/ml) immediately following exposure to virus resulted in a significant decrease in the number of infectious virus although general cellular pro-

RNA or RNA synthesis, mitosis, and cell growth) showed no differences from controls during the first 2 days after BrdU treatment. The physical numbers of virions (electron microscopy) were similar in BrdU-treated and untreated cultures, and no morphological differences were observed. Cell transformation was not affected by BrdU and virus-specific antigen appeared at approximately the same time (24 hr after infection) and in the same amounts (1:32 complement fixation titers⁻¹). The replicative genome of RNA-containing tumor viruses apparently contain DNA.

7 TRANSMISSION OF MOUSE NEUROBLASTOMA BY A CELL-FREE EXTRACT. (E.) Prasad, K. N. (Colorado Med. Ctr., Denver), J. Zambarnard, R. Her and M. H. VanWoert. *Nature* 228(5275): 997-1000, 1970.

Tyrosine hydroxylase enzyme activity and tumor induction by a cell-free extract (CFE) of neural tumors which originally developed in C1300 mice were investigated. CFE was prepared from putative neuroblastomas induced in mice by inoculation with tumor tissue from the original strain, and injected into mice in amounts of 0.4 ml per test mice; the tumorigenic efficacy of CFE was compared to that of tumor-transplanted neoplasms. CFE-injected mice developed palpable tumors in 18-40 days from time of injection, while mice which were given tumor transplants developed tumors in 8-10 days. All treated mice developed tissue-induced tumors, while 75% of CFE-injected mice developed tumors. Most tumors developed at the injection site (right axillary region); but the neck and intraperitoneal cavity were also affected. CFE-induced tumors were transplantable with the same efficiency as the tissue-transplantation-induced tumors. Tyrosine hydroxylase was found in similar amounts (30.5 nmoles/hr/g protein) in CFE-induced and transplantation-induced tumors, indicating that the CFE transmitted the same tumor as that which was transplanted.

8 ENZYMIC BLOCK IN THE SYNTHESIS OF GANGLIOSIDES IN DNA VIRUS-TRANSFORMED TUMORIGENIC MOUSE CELL LINES. (E.) Cumar, F. A. (Nat'l. Inst. Neurol. Dis. Stroke, Nat'l. Inst. Hlth., Bethesda, Md.), R. O. Brady, E. H. Kolodny, V. W. Parland and P. T. Mora. *Proc Nat Acad Sci* 67(2): 764-766, 1970.

Ganglioside synthesis was investigated in tumorigenic virally-transformed mouse cells to determine the reason for the decrease of gangliosides with an oligosaccharide chain larger than sialyllactose in virally transformed cells compared to parent cells or spontaneously-transforming cells. Mouse cell lines transformed by SV40 and polyoma virus were employed. Catabolism of gangliosides by enzymatic hydrolysis of sialic acid-labeled gangliosides was significantly increased in virally transformed cells, indicating that the decrease of gangliosides was not due to excessive catabolism. However, the enzyme catalyzing the transfer of *N*-acetylneuraminyl-

galactosylglucosyl ceramide was drastically reduced in virally transformed cells. These findings appear to indicate that the decrease of gangliosides in virally transformed cells is due to impaired synthesis of tri- and tetrahexosyl gangliosides in these cells, the impairment being due specifically to a block in a required step for the biosynthesis of these ganglioside homologs.

0569 ELECTRON MICROSCOPIC STUDY OF VIRUS-LIKE PARTICLES IN HUMAN LEUKEMIA AND ALLIED DISEASE. (E.) Yumoto, T. (Fac. Med. Kyushu U., Fukuoka, Japan). *Acta Haemat Jap* 32(4):578-592, 1970.

Biopsy material and plasma pellets from patients with leukemia and lymphoma conditions were studied under the electron microscope to detect virus particles in human leukemia and related conditions. Type C virus particles resembling those associated with murine leukemia were found in plasma pellets prepared from 7 of 13 leukemia or lymphoma patients. These particles were generally spherical, averaging 1800 Å in diameter; some exhibited a tail-like structure. Biological activity of these virus-like particles has not yet been demonstrated. The examination of ultra-thin sections of leukemic tissues revealed only occasional virus particles, very few in number. A virus-like particle resembling budding at the plasma membrane was observed in a biopsied lymph node specimen from a patient with Hodgkin's disease. Occasionally intracisternal and intracytoplasmic type A virus particles were also seen in leukemic cells and reticuloendothelial cells; intracytoplasmic type A particles were present only in the cytoplasm of plasma cells.

0570 VIROLOGICAL STUDIES ON HUMAN LEUKEMIA AND ALLIED DISEASES. (E.) Ito, Y. (Aichi Cancer Ctr., Nagoya, Japan). *Acta Haemat Jap* 32(4):569-577, 1970.

The possibility of a viral etiology for leukemia and allied diseases was examined in transformed "whole" human embryonic (THE) cell lines established from human embryonic cells and the cell-free supernatant of leukemic cell cultures. Three cell lines (THE-1, -2, and -3) were established, but the THE-1 (derived from an epithelioid focus) became contaminated and was abandoned, while the remaining 2 cell lines (derived from round cell foci) grew in floating clumps, exhibited typical herpes-type or Epstein-Barr virus (EB) particles and lesions in #10 chromosome (the extra chromosome in the occasionally observed trisomy of the #10 chromosome also exhibited this lesion). Attempts to establish a transformed cell line from the lymphatic tissues of patients with Hodgkin's disease have not been successful. A carrier hypothesis in which lymphoblastoid cells presumably host the EB virus either in a repressed (dormant) or functioning state has been proposed (transfer of the EB virus genome from the carrier cell to a recipient may initiate the

neoplastic process by the action of or the interaction with the transferred virus genome).

- 0571 THE INCIDENCE OF "LEUKOVIRUS" IN CULTURED HUMAN HEMATOPOIETIC CELLS. (E.) Moore, G. E. (Roswell Park Mem. Inst., Buffalo, N. Y.), H. Kitamura and J. Minowada. *J Surg Oncol* 2(4): 385-392, 1970.

Despite the difficulty of detection by electron microscopy, a herpes-like virus has been found in almost 30% of hematopoietic cell lines established from patients with leukemia, lymphoma, melanoma, and other malignancies and in approximately 70% of the cell lines derived from healthy individuals. The virus may destroy some cells in the affected cell line, but preliminary efforts to infect established non-virus-containing cell lines with the virus resulted in only 1 out of 5 takes.

- 0572 SELF-REPLICATING RNA IN LEUKEMIC CELLS. (E.) Watanabe, I. (Sch. Med. Keio U., Tokyo, Japan) and I. Haruna. *Acta Haemat Jap* 32(4):593-602, 1970.

Self-replicating RNA (viral RNA or genetic RNA) was detected in mouse and human leukemic cells by measuring RNA template activity (^3H -uridine triphosphate incorporation into the acid-insoluble fraction) on the specific RNA-dependent RNA polymerase (RNA replicase). Poliovirus-infected HeLa cells, echovirus-infected FL cells, and Friend virus leukemic cells of mice contained self-replicating RNAs. Ehrlich ascites tumor cells and human acute myeloid leukemic cells were found to contain RNA-dependent RNA polymerase and its template RNA. An ethine derivative (M1124), which is a specific inhibitor for RNA replicase of Q β phage, inhibited specifically the RNA-dependent RNA polymerase from tissues of mice with Friend disease, poliovirus-infected HeLa cells, and myeloblasts of human acute myeloid leukemia, suggesting that these polymerases are RNA replicases.

- 0573 EXCRETION OF IMMUNOGLOBULINS IN BURKITT'S LYMPHOMA. (E.) McFarlane, H. (Dept. Chem. Path., U. Ibadan, Nigeria), R. O. Barrow, V. A. Ngu and B. O. Osunkova. *Brit J Cancer* 24(2):258-265, 1970.

Urine and blood samples were collected from 17 patients with Burkitt's lymphoma, in order to identify and quantitate the immunoglobulins in their urine and sera. Gel filtration revealed IgM in the urine of 4 of the 17 patients, and in none of the control subjects. This IgM emerged from Sephadex G200 column in 2 different peaks strongly suggesting subunits of the intact molecule. The total protein excreted in the urine of Burkitt's lymphoma patients is higher than in controls (127 mg vs 90 mg) for controls, and may be due to renal involvement. Intact IgA and IgG as well as fragments of IgG were present in the urine of all Burkitt patients as well as in controls. Twelve of 16 Burkitt's lymphoma patients had reduced serum IgM (0.57 vs 1.23

mg/ml for controls), and 6 of these had reduced serum IgG.

- 0574 EBV DNA IN BIOPSIES OF BURKITT TUMOR ANAPLASTIC CARCINOMAS OF THE NASOPHARYNX. (E.) Zur Hausen, H. (Inst. Virol. U. Wurzburg, Germany), H. Schulte-Holthausen, G. Klein, W. Henle, P. Clifford and L. Santesson. *Nature* (5276):1056-1058, 1970.

Epstein Barr (EB) viral DNA in tumor cells of Burkitt's lymphoma and nasopharyngeal carcinoma were detected and quantitated by the nucleic acid hybridization technique. Cellular DNA annealed with increasing amounts of EBV ^3H -DNA permitting calculation of viral genome equivalents/cell. Burkitt tumor cells contained 2-26 genome equivalents and nasopharyngeal carcinomas contained 1-19 genome equivalents, while other tumors tested (Marek's disease, Hodgkin's disease, squamous cell carcinoma) and human KB cells, Nil-2 cells of hamster origin, cytomegalovirus-infected Wi-38 cells failed to anneal. Positive controls (an EBV carrier cell line D 75) hybridized with 17% of the input EBV ^3H -genome equivalents/cell. Studies of cellular DNA with herpes simplex virus (HSV) ^3H -DNA indicated that the positive control (DNA from HSV-infected Nil-2 cells) annealed with 17% of the input ^3H -DNA while the D 75 cells failed to anneal. Nucleic acid is regularly detected in biopsies of Burkitt's lymphomas and anaplastic carcinoma of the nasopharynx.

- 0575 VIRAL ETIOLOGY OF HUMAN MALIGNANT LYMPHOMAS. (E.) Oboshi, S. (Nat'l Cancer Ctr. Res. Inst., Tokyo, Japan). *Acta Haemat Jap* 32(4):619, 1970.

The relation of Burkitt's tumor and childhood lymphomas was discussed, and 5 continuous suspension cultures that were derived from human lymph nodes were characterized. The starry-sky appearance of Burkitt's tumor (macrophages interspersed among tumor cells) was frequently observed in children's cases of conventional lymphosarcoma and reticulum cell sarcoma but rarely seen in adult cases (suggesting a relation to childhood lymphomas in general). The characteristic primitive appearance, uniform size and maturity of Burkitt's tumor cells were also detected in 2 cases of poorly differentiated lymphosarcoma. Leukemic transformation rarely occurred in Burkitt's tumor, but once it did the disease could not be distinguished from lymphatic leukemia, indicating that these diseases may be different manifestations of the same entity. Of the 5 cell lines established, RS-2, RS-3, IM-1 contained normal lymphoreticular cells; MC-12 contained both neoplastic and normal lymphoreticular cells. The cells of RS-3 and MC-12 reacted with antibody to only 1 class of immunoglobulins (anti-IgA and anti-IgG, resp.), and RS-2 reacted with anti-IgG and anti-IgM, while RS-3 and MC-12 reacted with all 3 classes (anti-IgG, anti-IgM, and anti-IgA). The Epstein-Barr virus was detected in all 5 cell lines indirectly by immunofluorescence and in the RS-2 and MC-12 lines

tly by electron microscopy (the larger amounts of these cell lines may explain the detection in these cell lines).

6 SO-CALLED C-MARKER CHROMOSOME AND EPSTEIN-BARR VIRUS. (E.) Whang-Peng, J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), P. Ober and T. Knutsen. *J Nat Cancer Inst* 45(4): 839, 1970.

For human cell lines, 2 infected with Epstein-Barr virus and 2 already containing the virus, were subjected to cytogenetic studies to detect the presence of the "C marker" chromosome, a chromosome having a distinctive secondary constriction or chromosome gap in the long arm of 1 or both chromosome pairs; the aim was to test the specificity of marker chromosome as an indicator of present or past infection with Epstein-Barr virus. In each cell the incidence of gaps and secondary constrictions increased as the total number of chromosomal aberrations increased. Only 1-2% of the cells in lines with 20-90% Epstein-Barr virus-infected cells had the C marker chromosome, and there was no evidence that this abnormality was related to Epstein-Barr virus. Apparently, the C marker chromosome is a random gap caused perhaps by a nonspecific viral infection and not a true secondary constriction.

7 INFECTIOUS MONONUCLEOSIS: SERUM ANTIBODIES AGAINST THE EPSTEIN-BARR-VIRUS. (E.) Gsell, H. O. (Inst. Microbiol. Hyg., U. Basel, Switzerland) and B. Müller. *Klin Wschr* 19(19):1107-1110, 1970.

The presence of Epstein-Barr virus (EBV) serum antibodies and heterophilic infectious mononucleosis (IM) antibodies was investigated in 13 IM patients; they were examined within 28 days of the onset of illness and 7-96 days later. Two of these patients had heterophilic IM antibodies had no EBV antibodies; another patient had first a positive and later a negative EBV antibody test, and one patient exhibited a positive EBV test 68 days after the onset of IM, following a recurrence of IM. It was concluded that approximately 10-15% of the IM patients have no EBV antibodies and that possibly IM could not be attributed to a single etiological factor. The role of the EBV as the main etiological factor of IM is still open.

8 INCREASE IN ANTIBODY TITER AGAINST THE EBV-ASSOCIATED MEMBRANE ANTIGEN COMPLEX IN BURKITT'S LYMPHOMA AND NASOPHARYNGEAL CARCINOMA AFTER LOCAL IRRADIATION. (E.) Einhorn, N. (Karolinska Hosp., Stockholm, Sweden), G. Klein and P. Lifford. *Cancer* 26(5):1013-1021, 1970.

The effect of local irradiation (200-6500 r) on the titer of the antibody against the Epstein Barr virus-associated membrane antigen complex in Burkitt's lymphoma and nasopharyngeal carcinoma was studied by titrating the blocking activity of antibodies in the serum against a fluorescein isocyanate-conjugated reference immunoglobulin (F-

Mutua) derived from a case of Burkitt's lymphoma in long term remission. The sera from patients were tested before, at the termination of, and 6-9 weeks after local irradiation of the tumor with Burkitt's lymphoma-derived lymphoblastoid cell lines as target cells. Significant increases in the titer of membrane-reactive antibodies were observed at several serial dilution levels in sera of 2 patients with Burkitt's lymphoma and 3 patients with nasopharyngeal carcinoma but not in the sera of control patients (Hodgkin's disease, laryngeal carcinoma, and lymphosarcoma).

0579 SURFACE ANTIGENS ON LYMPHOBLASTOID CELLS DERIVED FROM NASOPHARYNGEAL CARCINOMA. (E.) De Schryver, A. (Karolinska Inst. Stockholm, Sweden), G. Klein and G. De The. *Clin Exp Immun* 7(2):161-171, 1970.

The Epstein-Barr virus-associated surface antigens of Burkitt's lymphoma and infectious mononucleosis derived lymphoblastoid cell lines were compared with the corresponding surface antigens of a lymphoblastoid cell line from a case of nasopharyngeal carcinoma for their reactivity with Epstein-Barr virus positive reference conjugates and for their blocking reactions with sera derived against the conjugates. The reactivity of the nasopharyngeal carcinoma cells correlated well with the Burkitt's lymphoma and infectious mononucleosis type cells in blocking tests with reference conjugates (r of 0.90 with Mutua-conjugate and r of 0.66 with Kipkoeh-conjugate) and r of 0.60 with unconjugated sera. The results do not support the existence of membrane expressed antigenic differences between nasopharyngeal carcinoma and Burkitt's lymphoma or infectious mononucleosis derived cell lines, although differences may exist which were not detected with these methods.

0580 SINGULARITY OF ONCOGENIC ACTIVITY OF STRAIN MC29 AVIAN LEUKOSIS VIRUSES. (E.) Beard, D. (Duke U. Med. Ctr., Durham, N. C.), J. F. Chabot, A. J. Langlois, E. A. Hillman and J. W. Beard. *Arch Geschwulstforsch* 35(4):315-325, 1970.

White leghorn chicks, 1-15 days old, were given i.p. or i.v. inoculations of avian tumor virus, strain MC29, obtained from diseased chicks or from tissue culture in order to investigate the host's oncogenic response to strain MC29 virus. Chicken response to strain MC29 virus was characterized by the formation of neoplasms derived chiefly from myeloid hematopoietic tissue, including myelocytoma, anaplastic sarcoma, and myelocytomatosis. Erythroid and lymphoid tumors were also observed. Kidney tumors included cystadenoma, and liver tumors included rifted adenoma and carcinoma. Tumors of the peritoneum, epicardium and pericardium included mesothelioma and chondroma. The liver was the preferred site for various growths varying from many nodules to general enlargement due to myelocyte infiltration. MC29 virus infection was generally not leukemogenic. MC29 responses which are unique to neoplasms caused by other leukosis or

avian tumor viruses include primary liver growth and the induction of mesotheliomas in the peritoneum or pericardium. Another singular activity of MC29 is rapid infection and massive alteration of chick embryo cells. These findings suggest an etiologic individuality for strain MC29 compared to other viral strains causing erythroblastosis or myeloblastosis.

- 0581 THE INFLUENCE OF ULTRAVIOLET-INACTIVATED SENDAI VIRUS ON MAREK'S DISEASE VIRUS INFECTION IN TISSUE CULTURE. (E.) Hlozanek, I. (Czechoslovak Acad. Sci., Prague). *J Gen Virol* 9(1):45-50, 1970.

Mixtures of Marek's disease virus (containing 23,000-46,000 plaque-forming units) and chick kidney cells were exposed to UV-inactivated Sendai virus (1000-4000 hemagglutination units) in an attempt to determine whether the inactivated Sendai virus affected the transfer of Marek's disease virus from infected to uninfected cells. The presence of UV-inactivated Sendai virus increased the transfer of Marek's disease virus from infected to uninfected chick kidney cells by as much as 50-100%. This effect was seen after incubation of infected and uninfected chick kidney cells in the presence of UV-inactivated Sendai virus at 4°; only a slight further increase in transfer of infection with subsequent incubation at 37° was seen. The close apposition of infected and uninfected cells occurring during the agglutination produced by treatment with UV-inactivated Sendai virus in the cold, rather than complete cell fusion may have been the main means by which the transfer of infection was increased by treatment with UV-inactivated Sendai virus. However, phytohemagglutinin stimulated agglutination was ineffective in transferring the infection, which indicates that this effect is specific for Sendai virus.

- 0582 ISOLATION OF A SECOND AVIAN LEUKOSIS GROUP-SPECIFIC ANTIGEN 9gs-b) FROM AVIAN MYELOBLASTOSIS VIRUS. (E.) Allen, D. W. (Massachusetts Gen. Hosp., Boston,), P. S. Sarma, H. D. Niall and R. Sauer. *Proc Nat Acad Sci* 67(2): 837-842, 1970.

The isolation of a group-specific antigen (Gs-b) from avian myeloblastosis virus is described. Avian leukosis virus from peripheral blood of leukemic chicks was treated with Tween 80 and ether, and subjected to column chromatography and carboxymethyl-cellulose chromatography. Immunological examination of the isolated antigen was conducted by gel electrophoresis, complement-fixation tests, and N- and C-terminal amino acid analysis. Chromatographic analyses of the antigen constituents of the viral protein showed that antigen gs-a was eluted at pH 5.2, whereas the known antigen gs-b was eluted at pH 6.1. The molecular wt of gs-a was about 20,000, while that of gs-b was 11,000. Complement fixation titers of the antigens at concentrations of 0.5 mg/ml were 512 for gs-a and 64 for gs-b, using anti-gs-a rabbit serum as antiserum. Leucine was the only N-terminal amino acid evident after reaction of gs-b

with ¹⁴C-dinitrofluorobenzene, while proline was the N-terminal residue of gs-a.

- 0583 STUDIES ON SINGLE FOCI OF HEMATOPOIETIC TRANSFORMED BY AVIAN MYELOBLASTOSIS VIRUS. (E.) Moscovici, C. (VA Hosp., Gainesville, FL) and M. Zanetti. *Virology* 42(1):61-67, 1970.

The cultivation of myeloblasts from single foci obtained after avian myeloblastosis virus (AMV) infection of 3 different genetic types of chick embryo yolk sac cultures is described. AMV dilutions of 10¹ yielded an average of 200 transformation foci/culture dish, and the virus dilution 10³ yielded 2 foci at most. Transformed foci were transferred to feeder cultures of Japanese quail fibroblasts, and supernatant fluids from culture foci were subjected to fluorescence and interference tests and were injected into embryonated chicken eggs to test for the presence of infectious virus; foci were found to contain viruses of group A or B. Several foci were found to be free; these nonproducer myeloblasts were infected with 4 different nontransforming avian leukosis viruses, including Rous-associated virus 7 and 2 strains of myeloblastosis-associated virus in an attempt to recover avian myeloblastosis from the nonproducing cells. Avian myeloblastosis virus could be recovered only when either strain of Rous-associated virus was added to nonproducing cultures.

- 0584 MECHANISM OF CARCINOGENESIS BY RNA VIRUSES: III. FORMATION OF RNA-DNA COMPLEX AND DUPLEX DNA MOLECULES BY THE DNA POLYMERASE(S) OF AVIAN MYELOBLASTOSIS VIRUS. (E.) F. K. (Aichi Cancer Ctr., Nagoya, Japan), J. T. J. W. Beard, D. Beard and M. Green. *Proc Nat Acad Sci* 67(3):1432-1439, 1970.

Steps in DNA synthesis by DNA polymerase of avian myeloblastosis virus (AMV) were investigated. DNA was prepared from the plasma of diseased birds. DNA polymerase activity was exposed by treatment with the nonionic detergent Nonidet P-40 (0.05%). DNA polymerase in the virus displayed a rapid synthesis of viral DNA, consisting of the formation of an RNA-DNA hybrid molecule, and duplex DNA molecules. The kinetics of deoxythymidine triphosphate incorporation into DNA were biphasic: an initial rapid reaction for 4 min at 37°C with a minimum polymerization rate of 10-20 nucleotides/sec, and a second reaction at about half the initial rate. RNA-DNA complexes were detected as early as 3 min after the initiation of DNA synthesis; DNA from template was formed after 7, 20 and 60 min of reaction. Most of the free AMV DNA formed an RNA-DNA hybrid when annealed with viral RNA. Over half the free AMV DNA product was apparently double-stranded, since it was retained on hydroxyapatite after elution with 0.12 M phosphate buffer, and was resistant to *Escherichia coli* exonuclease I. The virus or calf-thymus DNA added to unmasked AMV DNA synthesis 4-16-fold if there was no competition with RNase, and 40-130-fold if RNase treatment

ceeded the enzyme assay. A single enzyme may form the RNA-DNA hybrid and the duplex DNA product; alternatively, 2 polymerases may be present in the reaction.

55 ISOLATION OF AMINO ACID ACCEPTOR RNA FROM PURIFIED AVIAN MYELOBLASTOSIS VIRUS. (E.) Erikson, E. (U. Colorado Med. Ctr., Denver, Colo.) and R. L. Erikson. *J Molec Biol* 52(2):387-390, 1970.

The aminoacylation capacity for various amino acids was tested in the fractional RNA component of the avian myeloblastosis virus which had previously been found to have a sedimentation coefficient of 18S, and to comprise 40% of isolated viral RNA. This fractional RNA was aminoacylated by aminoacyl-transfer RNA synthetases prepared from homogenates of chick embryos. Chick embryo RNA and the myeloblast RNA had nearly equal aminoacylation capacities for amino acids tested. Viral transfer RNA had acceptor activity for the amino acids valine, proline, glycine, methionine, asparagine and arginine at levels equal to or approaching that of an equal amount of transfer RNA from chick embryo or from the source of the RNA myeloblasts. Aminoacylation figures for avian myeloblastosis virus RNA and chick embryo RNA for various amino acids showed that viral RNA accepted 27.6 μ moles of valine/ μ g RNA, while chick embryo RNA accepted 19.0 μ moles of valine/ μ g RNA, while chick embryo RNA accepted 19.0 μ moles valine/ μ g RNA. Viral RNA and chick embryo accepted 3.9 and 5.9 μ moles proline/ μ g RNA, resp. The amino acids tyrosine, isoleucine, phenylalanine, threonine, and arginine were accepted in negligible amounts by the viral RNA. Apparently, host cells and the 4S RNA found in avian myeloblastosis virus do not have the same amino acid-accepting activity.

56 VIRAL DNA-DEPENDENT DNA POLYMERASE AND THE PROPERTIES OF THYMIDINE LABELED MATERIAL IN VIRIONS OF AN ONCOGENIC RNA VIRUS. (E.) Riman, J. (Inst. Organic Chem., Biochem., Czechoslovak Acad. Sci., Prague) and G. S. Beaudreau. *Nature* 228(270):427-430, 1970.

DNA-dependent DNA polymerase activity and a thymidine labeled material that were found in the virions of avian myeloblastosis (AMV) were studied by buoyant density gradients. Polymerase activity measured by the incorporation of 3 H-deoxythymidine triphosphate into acid insoluble material) was stimulated by DNA templates (intact or denatured) from birds and mammalian cells, but the enzyme activity (pmoles incorporated) with denatured bacterial (*Streptomyces chrysomalus*) DNA (rich in guanine and cytidine) was 15 times higher (15.10) than with the avian (0.97) or mammalian (1.00) DNA and 70 times higher than the endogenous (0.22) activity. The AMV enzyme lost activity when one of the 3 deoxynucleoside triphosphates (dATP, dGTP, or dTTP) was omitted from the incubation mixture indicating that a heteropolymer is the product of synthesis. Analysis of the phenol extract from a

reaction mixture with the polymerase and template DNA (*Streptomyces chrysomalus*) on a cesium chloride gradient indicated that the DNA copy corresponded to its template. 3 H-Thymidine labeled material isolated from AMV and banded on cesium chloride gradients showed a large fraction of the DNA rich in the guanine and cytidine content and a minor component rich in adenine and thymine.

0587 COILED STRUCTURE OF THE NUCLEOCAPSID OF AVIAN MYELOBLASTOSIS VIRUS. (E.) Lacour, F. (Inst. Gustav Roussy, Villejuif, France), A. Fourcade, C. Verger and E. Delain. *J Gen Virol* 9(1):89-92, 1970.

A method for the disruption of avian myeloblastosis virus and isolation of the nucleocapsid components is described. Pellets of avian myeloblastosis virus, partially purified from leukemic chicken plasma by differential centrifugation, were suspended in distilled water containing a final concentration of 0.05% (w/v) of deoxycholate and 0.05% (w/v) of Brij 58, freshly dissolved. Electron microscopic examination of the centrifuged suspension showed that the pooled material consisted of nucleocapsids. The nucleoids had an internal granular, organized structure consisting of an annular form, a loose coil or volute, and an unrolled form with a diameter of 30-70 nm and a length of 0.5-1 μ m. The possibility that the structures observed were derived from mycoplasma was excluded by the absence of mycoplasma in both aerobic and anaerobic plasma cultures.

0588 ULTRASTRUCTURAL STUDIES OF FELINE LEUKEMIA VIRUS. (E.) Dougherty, E., III (New York St. Vetr. Coll., Ithaca) and C. G. Rickard. *J Ultrastruct Res* 32(5-6):472-476, 1970.

Seven spontaneous and 5 experimentally-induced cases of feline lymphosarcoma were examined by electron microscopy for feline leukemia virus; tissues searched for virus included adrenal glands, bone marrow, liver, lung, pancreas and ovary. C-type viral particles were found in 11 of 12 bone-marrow samples, in 6/12 lymph nodes, in 5/15 thymuses, in 3/12 intestines, in 3/12 livers, in 3/12 spleens, and in 2/12 lungs. Envelope spikes and intermediate membranes of viral particles were found in 11/12 and 4/12 of cat lymphosarcomas, resp. The envelope spikes consisted of 2 bars, parallel, crossed or V shaped; they measured 70-150 Å in length; intermediate membranes were found equidistant between the bimolecular envelope and the nucleoid. The shape and number of envelope spikes was seemingly uniform enough to suggest that they may be normal structural parts of the viral particle.

0589 SEPARATION OF RNA-DEPENDENT DNA POLYMERASE ACTIVITY FROM THE MURINE LEUKEMIA VIRION. (E.) Gerwin, B. I. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), G. J. Todaro, V. Zeve, E. M. Scolnick and S. A. Aaronson. *Nature* 228(5270):435-438, 1970.

An RNA-dependent DNA polymerase was separated from intact murine leukemia virion by detergent treatment (0.02% Triton X-100) followed by sucrose gradient sedimentation. After a 15 hr banding polymerase activity peaked in the nucleoid region, in the region associated with the whole virion, and in the lighter region of the gradient. Polymerase activity which cosedimented with untreated virus was not inhibited by anti-MSV (murine sarcoma virus) serum, but assays on the treated virus revealed the nucleoid and soluble fractions to be almost completely inhibited by the same rat anti-MSV serum. The specific activity (^3H -thymidine triphosphate incorporated/ μg protein) was 3 times higher in the nucleoid fraction than in the intact virion fraction and soluble fraction from the same gradient, indicating that the DNA polymerase was located in the nucleoid.

- 0590 ABSENCE OF ALKALINE PHOSPHATASE IN RAT THYMIC LYMPHOMA INDUCED BY MURINE LEUKEMIA VIRUS. (E.) Doell, R. G. (Stanford U. Sch. Med., Calif.) and B. J. Mathieson. *Cancer Res* 30(10):2456-2457, 1970.

Mice and rats received intrathymic injections of a murine leukemia virus followed 1 wk later by 100 rads of whole-body X-irradiation, and the resulting thymic lymphomas were sectioned and the sections tested for alkaline phosphatase activity. In mice, after latent periods of from 4.2-5 months tumor incidence ranged from 89-100%, and alkaline phosphatase activity was found in the plasma membranes of 5/11 to 18/26 of tested mice tumors (an incidence of about 60%). In rats, tumor incidence after 4 months was 100% and alkaline phosphatase activity was negligible. Whether or not alkaline phosphatase activity in thymic lymphoma cells is intimately related to the neoplastic transformation process is unclear; however, the data suggest that alkaline phosphatase activity is an incidental occurrence, not related to transformation.

- 0591 CHROMOSOMES OF THE MURINE LEUKEMIA VIRUS INDICATOR CELL LINE XC. (E.) Nelson-Rees, W. A. (U. California, Oakland). *Chromosoma* 31(1):51-60, 1970.

Karyotype analyses were performed on cells derived from tumors induced in rats by Rous sarcoma virus. Cells were hypodiploid, having 41 chromosomes and stem lines existing in the range of diploidy at 40-42 chromosomes. The longest chromosome was subtelocentric and often exhibited 2 or 3 secondary constrictions. Tumor cells had approximately 18 size-graded metacentric chromosomes and 1 pair of subtelocentric chromosomes. Unconventional chromosomes which did not resemble those ordinarily found in *Rattus norvegicus* consisted of about 7 size-graded, 2-armed chromosomes which were significantly smaller than the next largest chromosomes.

- 0592 LEUKEMOGENIC ACTIVITY OF THE RADIATION INDUCED LEUKEMIA VIRUS OF THE MOUSE. (Fr.) Duplan, J. F. (Curie Found., Paris, France), P. Monnot and P. B. Mistry. *Bull Cancer* 57(1):23-30, 1970.

The presence of a leukemogenic virus in normal mouse spleen extracts prepared from C57BL male female animals 300-500 days old was established. Acellular spleen extracts (Tyrode's solution) were injected into 31 one-month-old isogenous healthy mice (0.2 ml, i.p., once or twice) and to 28 mice the same age group exposed to whole body irradiation following inoculation (175 rad, 2-4 times at weekly intervals, starting at age 40-45 days). Irradiated animals were treated i.v. with 7×10^6 - 10^7 cells of isogenous bone marrow 4 hr before or 24 hr after the last exposure. Leukemia developed in 48% of nonirradiated, in 45% of the irradiated and in 100% of the control (nontreated) animals. Of these, 11 tumors (lymphoreticuloses) appeared in 11 out of 28 nonirradiated, spleen extract-inoculated mice, 10 out of 28 irradiated and inoculated mice. These tumors were not transplantable when inoculated or i.p. to isogenous young animals; however, 5 tumors developed in 50% of these animals 300-600 days after tumor inoculation. Irradiated animals developed transplantable lymphosarcomas of the thymus at days.

- 0593 INTRACISTERNAL A-TYPE PARTICLES IN MURINE NEOPLASIAS WITH AND WITHOUT PARAPROTODERMIC PRODUCTION. (E.) Ebbesen, P. (Inst. Tumor Virus Res., U. Copenhagen, Denmark) and M. H. Nielsen. *Acta Path Microbiol Scand* 78(3):390-394, 1970.

Tissue blocks prepared from the peripheral lymph nodes, spleen, and thymus of mice bearing immunoplasma cell neoplasias induced by subcutaneous injection of murine leukemia virus were examined electron microscopically to locate virus-like particles. A-type particles located in the cisternae of the endoplasmic reticulum and in the perinuclear space were the virus-like particles observed; these particles averaged 70 m μ in transverse diameter. They showed 2 electron-dense shells around a 30 m μ wide electron-translucent core. In most instances the particle surface was covered by a layer of granular material with moderate electron-density. A few electron-dense granules were noted in the core of some A-type particles. The A-type particles apparently were formed by inward budding from the membrane of the endoplasmic reticulum, and occurred whether or not the neoplasm produced paraproteins.

- 0594 GENETIC SUSCEPTIBILITY TO LEUKEMOGENIC INTRATHYMIC INOCULATION OF CELL-FREE SUPERNATANTS OF THE THYMUS FROM FIVE-MONTH-OLD, NONLEUKEMIC AKR MICE. (E.) Nakakuki, K. (Sch. Med. Prefect. U., Japan). *Gann* 61(4):393-396, 1970.

Cell-free supernatants from thymus preparation from 5 month-old grossly non-leukemic AKR mice were inoculated into the thymus of 10-15 day-old mice (AKR/Ms, C3Hf/Bi, C57BL, A/Jax, DBA/2, (C3Hf x C57BL)F₁, and (C57BL x ARR)F₁), in amounts ranging from 0.02-0.03 ml/mouse, for the purpose of investigating the incidence of leukemia development in tests with different inherited susceptibility to leukemia. Leukemias which developed were all thymic lymphomas with or without hepatosplenomegaly and lymph

involvement. The incidence of leukemia was 100% in mice of strain AKR, C3Hf, and (C3Hf x AKR) F_1 . However the latent period of leukemia development varied greatly in these 3 strains, with AKR and (C3Hf x AKR) F_1 strains showing short latencies (56 and 67 days, resp.), and C3Hf showing a latency ranging from 72-200 days. Mice of other strains except C57BL showed lower leukemia incidences, but in no case was the incidence insignificant, since all these strains had naturally very low incidences of spontaneous leukemias.

95 INVESTIGATION OF IMMUNIZING PROPERTIES AS WELL AS INTERFEROGENICITY OF SOME MURINE LEUKEMIA VIRUSES. (E.) Mazurenko, N. P. (Acad. Med. Sci., USSR, Moscow) and E. S. Revazova. *Arch Schwulstforsch* 35(4):308-314, 1970.

Mice were inoculated with vaccines prepared from Friend, Rauscher, and Mazurenko virus inactivated with formalin (3 doses of 0.3 ml, i.p., at weekly intervals) to determine if these viruses could produce antibodies not only to homologous virus but to the other viruses. Only in the instance of vaccination with inactivated Friend virus was immunization observed; challenge with Friend virus 3 wk after termination of vaccination resulted in only 10% mortality compared to 97% mortality in controls. Rauscher and Mazurenko inactivated viruses did not protect against homologous virus challenge, and none of the vaccines immunized against any of the other viruses, even when adjuvant was employed. However, with adjuvant, both Friend and Rauscher vaccines protected against homologous virus challenge. Vaccination of mice with combined Friend and Rauscher vaccines produced resistance to the Rauscher virus. Friend virus inactivated with formalin induced the production of interferon in mice susceptible to this virus.

96 GROUP-SPECIFIC ANTIGEN OF MURINE LEUKEMIA VIRUSES IN MICE OF LOW-LEUKEMIC STRAINS. (E.) Abelev, G. I. (N. F. Gamaleya Inst. Epidem. Microbiol., Moscow, USSR) and D. A. Elgort. *Int J Cancer* 6(2):145-152, 1970.

The presence of a group-specific antigen of murine leukemia viruses in mice of low leukemic strains, and in other mice and rats, was investigated. Mice of varying strains, leukemic mice, mouse embryos, and rats bearing Moloney rat sarcoma were used as tissue donors, and tissue cultures were exposed to rabbit monospecific anti-murine leukemia virus group-specific antigen antiserum used for detection of the antigen. An indirect immunoradiography technique was used in the analyses of the tissue cultures for antigen to permit the detection of trace amounts of antigen. Anti-murine leukemia virus group-specific antigen was found in all mouse strains, both high- and low-leukemic; AKR strain mice had the highest levels of antigen, and C57BL/6 and B10D2 had the lowest. Highest levels of antigen generally were found in spleen and thymus of embryos of C57BL/6 and BALB/c strain animals. No antigen could be found in the spleens of newborn or

adult rats; however, antigen was present in high amounts in rats with sarcomas induced by Moloney virus.

0597 PREVALENCE OF MURINE C-TYPE RNA VIRUS GROUP SPECIFIC ANTIGEN IN INBRED STRAINS OF MICE. (E.) Myers, D. D. (Jackson Lab., Bar Harbor, Me.), H. Meier and R. J. Huebner. *Life Sci* 9(18):1071-1080, 1970.

Sera from mice bearing C-type virus-induced tumors were subjected to the complement fixation test for the detection in these sera of group-specific antigen to murine C-type RNA virus. The group-specific antigen was detected in 80% of high-leukemia strains of mice (AKR/J, C58/J, SJL/J), 41% in intermediate-leukemia strains (RF/J) and 23% in low-leukemia strains (A/HeJ, A/J, BALB, CBA/J, C3HeB/FeJ, C57BL/6J, C57BL/10J, C57BR/cdJ, C57L/J, DBA/2J, SWR/J). The prevalence of antigen increased with age in most strains, and genetically related strains had a similar incidence. Apparently, endogenous-physiological factors such as age, and exogenous environmental factors can modify the patterns of virus expression, although that pattern is partially genetically determined.

0598 IMMUNOFLUORESCENT STUDY OF THE GROUP-SPECIFIC ANTIGEN OF MURINE LEUKEMIA VIRUSES. (E.) Lejneva, O. M. (N. F. Gamaleya Inst. Epidem. Microbiol., Moscow, USSR) and G. I. Abelev. *Int J Cancer* 6(2):153-159, 1970.

Monospecific antibodies to the group-specific antigen of the murine leukemia viruses were obtained using a new method in normal and malignant tissue. That the reaction was specific for murine leukemia virus antigen was confirmed by the specific inhibition of immunofluorescence after neutralization of the antibodies by partially-purified murine leukemia group-specific antigen. Indirect immunofluorescence demonstrated antibodies in Rauscher leukemic spleen cells of BALB/c mice (100% of mice tested were positive for antibodies) and in normal spleen cells of high-leukemic and some low-leukemic mice. The murine leukemia virus group-specific antigen was shown in cells of methylcholanthrene-induced sarcomas and in cells of tumors induced with polyoma virus (100% antibody positive). The murine leukemia virus group-specific antigen was not seen in III Af mouse sarcoma induced by Rous virus. In general, agar precipitation analysis of tissues gave the same results as immunofluorescence.

0599 CYTOTOXICITY *IN VITRO* OF PRELEUKAEMIC LYMPHOID CELLS ON SYNGENEIC MONOLAYERS OF EMBRYO OR THYMUS CELLS. (E.) Wahren, B. (Karolinska Inst., Stockholm, Sweden) and D. Metcalf. *Clin Exp Immun* 7(3):373-386, 1970.

The syngeneic or autoimmune reactivity of lymphoid cells from 2 high leukemic mouse strains (AKR and the C3H strain carrying Moloney virus) were tested on monolayers of syngeneic embryo and thymus target

cells *in vitro* to determine the importance of immunological reactions in the pathogenesis of leukemia. Cytotoxic reactivity was observed with lymphoid cells of AKR animals aged 3-36 wk (lesions in 16 out of 24 tests) and of C3H animals aged 3-8 wk (lesions in 10 out of 11 tests), but not in younger AKR animals (less than 3-wk-old), and low leukemic strains (C3H/BI and DBA/2 mice). Lymphoid cells from leukemic AKR mice showed reduced activity with lesions occurring in the embryo target cells in only 1 out of 6 tests. Target AKR and C3H-Moloney embryo monolayers contained little virus-induced G+ or M+ antigen, and target embryonic cells preincubated with antiserum directed against AKR G+ cells exhibited reduced cytotoxic effects. Assuming these cytotoxic reactions are genuine immunological responses, they may explain a secondary damage of virus-modified cells in neoplastic transformation by leukemia viruses; alternatively, they may indicate that AKR and C3H-Moloney mice are not completely tolerant to viral-induced antigens, explaining the long pre-leukemic period in these animals.

- 0600 EFFECT OF CONCURRENT MALARIAL INFECTION ON DEVELOPMENT OF VIRUS-INDUCED LYMPHOMA OF BALB/c MICE. (E.) Wedderburn, N. (Roy. Coll. Surg., London, England). *Lancet* 2(7683):1114-1116, 1970.

The effect of concurrent infection with *Plasmodium berghei yoelii* (Pby, 10^6 cells, i.p.) on the oncogenicity of Moloney leukemogenic virus (0.5 ml of a 20% extract, i.p.) was determined by the incidence of malignant lymphoma in host BALB/c mice. Only 1 out of 11 mice injected with the virus developed lymphoma (latent period of 20 weeks), while none of the 10 mice receiving Pby showed evidence of lymphoma after 6 months. Of the 12 mice injected with both agents within 5 min of each other, 10 showed signs of generalized lymphoma after 15-24 wk; and of the 13 mice receiving Moloney leukemogenic virus 10 days after Pby, 6 showed signs of lymphoma 15-26 wk after receiving the virus. A synergistic effect is suggested in the animals receiving Moloney leukemogenic virus with or after Pby.

- 0601 RNA SYNTHESIS IN NUCLEI ISOLATED FROM NORMAL AND FRIEND VIRUS-INFECTED MOUSE SPLEEN. (E.) Munson, B. R. (Roswell Park Mem. Inst., Springville, N. Y.), R. J. Fiel and J. L. Ambrus. *Cancer Res* 30(9):2414-2419, 1970.

RNA synthesis in the nuclei of spleen cells from normal mice and mice infected with Friend virus was assayed by measuring the amount of ^{14}C -ATP incorporated into a cold acid-insoluble residue. Nuclei from virus-infected spleen contained 2.8 times as much RNA as nuclei from normal spleen (RNA/DNA ratios of 0.627 and 0.225, resp.) Optimal reaction conditions for RNA polymerase activity at high and low ionic strengths were similar in normal and in virus-infected rat liver nuclei, except that a typically bell-shaped curve for the pH optimum was not obtained for the enzyme in the normal nuclei while the RNA polymerase activity of both normal and

Friend virus-infected nuclei was stimulated at low ionic strength, the level of activity in the spleen from virus-infected spleen cell was 4 times greater than in normal spleen cells. The differential response of RNA polymerase activity in normal spleen cells to high and low ionic strengths suggests that a factor other than the related DNA template activity is involved in the RNA polymerase activity found in metabolically stimulated tissues.

- 0602 ENHANCEMENT OF FRIEND LEUKEMIA VIRUS INFECTION IN MICE BY GUAROA VIRUS: QUANTITATION AND ACTION OF VARIOUS ONCOGENIC AND NON-ONCOGENIC VIRUSES. (E.) Spahn, G. J. (Nat'l. Inst., Nat'l. Inst. Hlth., Bethesda, Md.), W. R. L. Peters and M. A. Chirigos. *Appl Microbiol* 20(4):551-554, 1970.

The enhancement by guaroa virus of virus infection by Friend leukemia virus (FLV) was investigated in mice. Male mice from 6-8 wk old were given inoculations of guaroa virus in amounts of 4 LD₅₀ for suckling mice, followed 3 days later by infection with FLV in concentrations of 200 spleen-enlarging doses. Spleen-foci activity, spleen wt, and amount of infectious virus recoverable from plasma were markedly increased by infection with guaroa virus and FLV. Spleen in co-infected mice showed a more than 2-fold increase over mice infected with FLV only with receiving FLV at 200 spleen-enlarging doses. 74 spleen foci 7 days after infection and mice receiving both FLV and guaroa virus showing about 100 foci. Co-infected mice had mean spleen wts of 100 mg when infected with 20 spleen-enlarging doses of FLV, while mice receiving only this amount of FLV had a mean spleen wt of 100 mg. In plasma preparations of FLV alone, recoverable virus was barely detectable, whereas in co-infected mice there was a nearly 75-fold increase of infectious virus recovered. Co-infection of vesicular stomatitis virus and FLV produced a significant increase in spleen foci, but the increase did not approach that achieved with guaroa virus.

- 0603 FURTHER STUDIES ON THE BIOLOGICAL RELATIONSHIPS OF FRIEND VIRUS-INDUCED LEUKEMIC CELLS DIFFERENTIATING ALONG THE ERYTHROCYTIC LINE. (E.) Rossi, G. B. (Higher Inst. Sanit., Rome, Italy) and C. Friend. *J Cell Physiol* 76(2):171-179, 1970.

Replication and erythroid differentiation of Friend virus-induced leukemic cells were studied. Cells were injected i.v. into young mice before and after the second of 2 doses of X-radiation (950 r or 1200 rads, resp.). The forming unit (CFU) in the recipient spleens was 7-fold higher when injected before irradiation than the CFU obtained when the second radiation had been given shortly after the inoculation of cells. Serial passage of the cells from the colonies to irradiated hosts resulted in a marked increase of the CFU value, indicating that

population was capable of both self-replication and erythroid differentiation. The percentage of the inoculated cells reaching the spleen in the irradiated recipients was found to be approximately 15%. If the highest CFU value obtained from serial colony-to-colony passages is corrected by this factor, a final cloning efficiency of about 18% is demonstrated. Neither induced plethoria nor the administration of erythropoietin (1 U/mouse for 2 days) appeared to affect the spleen colony-forming ability of the leukemic cells. Erythroid differentiation is not detectable in the transplantable subcutaneous tumors which were used to initiate the tissue culture lines and which also are capable of inducing erythroid spleen clones in irradiated recipients. The theory that so-called microenvironmental factors influence the fate of stem cells with potential for differentiation may be supported by the lack of erythroid differentiation in these cells.

0604 ROLE OF RADIATION IN VIRAL LEUKEMOGENESIS. (E.) Yokoro, K. (Res. Inst. Nucl. Med. Biol., Hiroshima U., Japan) and N. Imamura. *Acta Haemat Jap* 32(4):620-628, 1970.

Male and female (Wistar/Furth) rats received 600 rads of total body X-irradiation in 4 doses of 150 rads at 5-day intervals followed by i.p. inoculation of 0.4 ml Gross leukemia virus; other rat groups received X-irradiation or virus inoculation alone. The aim was to investigate the possible synergistic action of total body X-irradiation and viral induction of leukemia in rats. Leukemia was not observed in rat groups which had received X-irradiation at 4-5 wk of age alone or in groups treated 8 wk of age with virus alone; however, the rats receiving combined treatment showed 55% leukemia induction with a latency of 77-213 days. Rats inoculated with virus alone at 2 days of age showed 100% leukemia induction. When cell-free filtrates made from lymphomas induced by the combined treatment were inoculated in newborn rats thymic lymphoma resulted in 13/14 of recipients. To test the effect of Gross virus on the immunological reactivity of the host during incubation, highly susceptible Sprague-Dawley rats were inoculated i.p. with 0.1 ml of the virus shortly after birth, and subsequently they were challenged with sheep red blood cells. Counts of plaque-forming cells in the spleen and mesenteric nodes of control rats showed that plaque-forming cells in spleen and nodes increased progressively while plaque-forming cells in virus-inoculated rats showed no increase. These results suggest that Gross virus induces in the susceptible host a state of immunological suppression well before the development of leukemia. The overall findings suggest that a synergistic action of irradiation and Gross virus is necessary for the induction of leukemia in young rats which are refractory to a single application of either agent.

0605 CELL-FREE TRANSMISSION OF MURINE MYELOID LEUKAEMIA. (E.) Tanaka, T. (Sch. Med. U. Leeds, England) and A. W. Craig. *Europ J Cancer* (4):329-333, 1970.

Liver and spleen extracts from mice having myeloid leukemia induced by radiation were centrifuged, and the resultant supernatant was injected i.v. into 1-3.5 month old mice at doses of 0.2-0.3 ml/mouse to determine if cell-free extracts prepared from leukemic organs would enhance the induction of murine myeloid leukemia. The incidence of myeloid leukemia following injection of supernatant was 38% with an average latency of 37 days. Filtration of the supernatant through Millipore filters of 0.45 or 0.8 μ porosity completely eliminated the infectivity of the supernatant; extraction of the filter with Hank's solution and inoculation of this wash into mice resulted in the development of leukemia in 2 of 6 animals. A filtrate prepared using 3.0 μ membrane filter and physiological saline was a suitable way of enhancing virus yields; 9 mice treated with such a filtrate all developed myeloid leukemia with a latency of 15-20 days. The results clearly indicate that variable numbers of virus particles were held on the filter surface or inside the filter pores, depending both on the medium used for organ extracts, and on the quality and porosity of the filters.

0606 DEMONSTRATION OF BIOLOGICAL ACTIVITY OF A MURINE LEUKEMIA VIRUS OF NEW ZEALAND BLACK MICE. (E.) Levy, J. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and T. Pincus. *Science* 170(3955):326-327, 1970.

A hamster tumor cell line transformed by Moloney sarcoma virus (10^5 cells) were cocultivated with embryo cells from BALB/c, NIH and the New Zealand Black mouse strain, in an attempt to demonstrate biological activity of murine leukemia virus in the latter cells. No focus-forming virus was released by hamster tumor cells when cocultivated with BALB/c or NIH cells or when the hamster tumor cells were infected with Rauscher murine leukemia virus; however, when Rauscher murine leukemia virus was added to cultures containing both hamster tumor cells and mouse cells, a focus-forming pseudotype virus was produced. Focus-forming virus was also produced by cocultivation of hamster tumor cells with New Zealand Black mouse cells, demonstrating the existence of murine leukemia virus in the latter cells. The titer of the New Zealand Black mouse-rescued sarcoma virus ranged from 5-100 focus-forming units/0.5 ml cocultivation fluid. The rescued virus presumably carried the New Zealand Black mouse leukemia virus coat.

0607 FREE AND MEMBRANE-BOUND POLYRIBOSOMES IN NORMAL AND RAUSCHER-VIRUS-INFECTED MOUSE SPLEEN CELLS. (E.) Burghouts, J. T. M. (Dept. Biochem, U. Nijmegen, Netherlands), A. L. H. Stols and H. Bloemendal. *Biochem J* 119(4):749-756, 1970.

The influence of Rauscher virus infection on polyribosome profiles was studied by isolating free and membrane-bound polyribosomes (in the presence of ribonuclease inhibitor to prevent degradation) and ribosomal monomers from normal and infected mouse spleens on discontinuous sucrose density

gradients. Leukemic infection increased RNA (mg RNA/mgDNA/g spleen) from both free (14.76 to 28.07) and membrane-bound polyribosomes (1.78 to 5.15) and produced an increase in spleen wt with a shift towards larger polyribosomal aggregates (electron micrographs revealed as many as 40 monomers/polyribosome). Sodium deoxycholate treatment (0.5%) of the membrane-bound polyribosomes from both normal and infected spleens before application to a continuous sucrose density gradient resulted in an increase of only 80 S particles (even in the presence of the ribonuclease inhibitor), suggesting that only the monomers are bound to membranes or that the solubilization by deoxycholate degraded the polyribosomes.

0608 AEROSOL TRANSMISSION OF RAUSCHER MURINE LEUKEMIA VIRUS. (E.) McKissick, G. E. (Vetr. Path. Lab., Merck & Co., Rahway, N.J.), R. A. Griesemer and R. L. Farrell. *J Nat Cancer Inst* 45(4):625-636, 1970.

Weanling mice were exposed to an aerosol of Rauscher murine leukemia virus (retained pulmonary dose of 2675 LD₅₀), with the result that 39.5% of aerosol-exposed mice developed leukemia during an observation period of 25 months from initial treatment. Mice in contact with aerosol-exposed cagemates also developed leukemia, indicating that horizontal transmission of Rauscher murine leukemia virus can occur. The leukemic response of the exposed mice was characterized by a diffuse neoplastic infiltration of the spleen and liver and dissemination of leukemic cells in the circulatory vascular system. These characteristics distinguished the response to Rauscher murine leukemia virus from a spontaneous, aleukemic, multifocal, splenic reticulum cell sarcoma which occurred in aged survivors. The finding that aerosols of a leukemogenic virus are infectious suggests that laboratory infection represents a potentially hazardous form of occupational exposure.

0609 HISTOPROLIFERATIVE EFFECT OF RAUSCHER LEUKEMIA VIRUS ON LYMPHATIC TISSUE: III. ALTERATIONS IN THE THYMIC-DEPENDENT AREA INDUCED BY THE PASSENGER LACTIC DEHYDROGENASE VIRUS. (E.) Snodgrass, M. J. (Oak Ridge Natl. Lab., Tenn.) and M. G. Hanna, Jr. *J Nat Cancer Inst* 45(4):741-759, 1970.

The destruction of small lymphocytes in the thymic-dependent region of lymphoid tissues of mice infected with Rauscher leukemia virus associated with a passenger lactic dehydrogenase virus (LDV) was investigated. Mice were given i.p. injections of Rauscher leukemia virus or LDV in doses of 10,000 or 10⁸ ID₅₀, resp.; spleens were subsequently removed and inspected microscopically with specific attention given to splenic lymphoid nodules. The presence and replication of LDV in the thymic-dependent area were confirmed. Morphologically typical LDV particles were localized intercellularly and in single membrane-bound vesicles of phagocytic reticular cells in the marginal zone at the earliest

intervals after inoculation with Rauscher leukemia virus and/or LDV, corresponding to the well-known events of the exponential phase of the plasma viremia. LDV particles were first seen in the thymic-dependent area, where they were associated with similar phagocytic reticular cells, 24 hr after inoculation. Complete intercellular virus particles were observed throughout the experiment, and incomplete intracellular particles were not present. The virus population in this region increased until day 2, when cellular necrosis and macrophage infiltration were at a peak. On day 4 these effects were cleared, leaving the prominent reticulum, and very few virus particles were present. Although lymphocytes of thymic origin were adversely affected, the result of LDV infection, phagocytic reticular cells in the marginal zone and thymic-dependent area appeared to be the target cell of this virus. The importance of cell-mediated immunity, which is suppressed by LDV, in the host defense against viral infection is supported by the augmented Rauscher leukemia virus-associated splenomegaly after infection with LDV. A synergistic interaction between the passenger LDV and the Rauscher-virus-induced pathogenic process may be indicated by this phenomenon.

0610 INDUCTION OF LYMPHOMA IN BALB/c MICE BY ROWNSON-PARR VIRUS (RPV). (E.) Carter, R. L. (Chester Beatty Res. Inst., London, England), F. C. Chesterman, K. E. K. Rowson, M. H. Salama, and N. Wedderburn. *Int J Cancer* 6(2):290-303, 1970.

Young adult mice received i.v. injections of 10⁶ of a 1:10 dilution of Rowson-Parr virus; in 1 experiment, animals were killed between 4-48 wk of age, and in another, animals were allowed to live out their life-spans. The oncologic response of the mice developed in 4 stages. In stage I there was initially a short-lived phase of moderate splenic enlargement and reactive hyperplasia which resolved, followed by stage 2 which was characterized by a persistent period of slight splenomegaly and low-grade non-specific reactive hyperplasia; stage III neoplasms occurred in the reticulum of the spleen and in the Malpighian follicles of the spleen and were initially confined to these structures. Later (stage IV) there was progressive replacement of splenic pulp and increasing involvement of lymph nodes, liver and thymus; some animals developed terminal leukemia. Stages III and IV occurred in 45% of all test mice; none of these animals survived for more than a year after infection. Four Rowson-Parr virus-infected mice developed lymphomas and leukemias of other histological types. No reticulum-cell neoplasms were found in the uninjected control animals. Two prominent features of the reticulum cell lymphoma associated with Rowson-Parr virus were the biphasic nature of the host response with respect to time and the lymphoma being preceded by long-sustained reactive changes; reactive and plastic changes arose sequentially in the same organ, and perhaps involved the same cell-type, phagocytic reticulum cells. The thymus is apparently involved until late in the disease course in lymphomas produced by Rowson-Parr virus.

11 MULTIPLICATION OF ADENOVIRUS IN HETERO-KARYOCYTES PRODUCED BY FUSION OF INFECTED PERMISSIVE AND NONPERMISSIVE CELLS. (E.) Weber, J. H. U. Sherbrooke, Quebec, Canada) and S. Mak. *Virology* 42(2):540-543, 1970.

The effect of fusion of permissive and non-permissive cells with inactivated Sendai virus on adenovirus 12 multiplication was investigated. In the first of a series of 4 experiments, BHK₂₁ hamster cells (non-permissive) were pretreated with ³H-thymidine, infected with adenovirus 12 (5 plaque-forming units/cell) and fused with human cells (HEp₂). Neither nuclear inclusion bodies nor virus-antigen were found in the nuclei of the human cells in significant amounts; however tumor antigen was found in 44-51% of the unfused hamster cells. In another experiment the virus-infected heterokaryocytes were disrupted by sonication, and the resulting suspension was assayed for virus capable of inducing tumor antigen in human cells; human cell nuclei resident with an infected hamster cell nucleus positive for tumor antigen yielded less than 0.005 plaque-forming units/cell, whereas human cell nuclei containing adenovirus-induced inclusion bodies produced 25 plaque-forming units/cell. Infectious virus was recovered from polycaryocytes formed from the fusion of adenovirus 12-infected and non-infected HEp₂ cells and from heterokaryocytes formed from the fusion of non-infected BHK₂₁ and infected HEp₂. The presence of HEp₂ cytoplasm or nucleus at the time of infection appears to be necessary for the expression of the viral genome, and it seems that no infectious virus can be recovered from adenovirus 12-infected BHK₂₁ cells even by early fusion with HEp₂ cells.

12 STIMULATORY AND INHIBITORY EFFECTS OF ADENOVIRUS AND SV40 ON VARIOUS VIRUS-RECEPTOR SYSTEMS. (E.) Berman, L. D. (Boston City Hospital) and C. Chany. *Arch Ges Virusforsch* 30(2-3): 23-216, 1970.

Cultures of rat, mouse, chicken embryo fibroblast, and hamster cells were infected with adenoviruses or SV40 (0.1 ml of virus) and the infected cultures were subsequently superinfected with vesicular stomatitis virus (VSV), encephalomyocarditis virus or vaccinia virus in order to study changes in superinfectibility brought about by acute adenovirus or SV40 infection. Infection with these viruses caused marked inhibition of superinfection with VSV, encephalomyocarditis virus, or vaccinia virus, with inhibition most marked with adenovirus infection of mouse cells, where a transitory phase of stimulation was frequently demonstrated immediately after adenovirus infection and where inhibition of superinfection reached 100%. The inhibitory phase usually commenced 2-6 hr after infection and depended on infection with intact virions; the inhibitory substance cosedimented with the virions, was completely inactivated by heating at 56°C for 1/2-1 hr but was unaffected by UV-irradiation (2.6-2.8 x 10⁶ ergs/mm²) and crystalline trypsin (1000 µg/ml). Binding of virus by antiserum did not prevent the inhibition, and inhibition could not be explained

by differences in adsorption, interferon production, chromosome breakage, or the effect of soluble capsid antigens. In contrast to acute adenovirus infection, in which the challenge virus was inhibited, mouse cells showed increased sensitivity to VSV after transformation with SV40.

0613 STRUCTURAL PROTEINS OF ADENOVIRUSES: IV. SEQUENTIAL DEGRADATION OF THE ADENOVIRUS TYPE 2 VIRION. (E.) Prage, L. (Dept. Microbiol., Uppsala U., Sweden), U. Pettersson, S. Höglund, K. Lonberg-Holm and L. Philipson. *Virology* 42(2): 341-358, 1970.

Methods were designed for disintegrating the adenovirus type 2 virion in order to investigate the structural units of the highly purified virus. Degradation procedures included dialysis against Tris-maleate buffers, freezing and thawing, and dialysis with pyridine. Dialysis against Tris-maleate buffers in the pH range 6.0-6.6 resulted in a loss of infectivity and in a quantitative release of pentons from the virions. At room temperature, these pentonless virions rapidly also released 5 or 6 hexons original penton unit. The remainder of the capsid was further disintegrated by repeated freezing and thawing, which released hexons in a non-aggregated form and also a precipitated DNA-protein complex. Two major protein components could be extracted from the latter with mineral acids. Amino acid analysis of these internal DNA complexed proteins revealed that they were highly basic, with an arginine content of 19%. Three or more low-molecular weight antigens distinct from hexon, penton base, fiber, and basic core proteins were also released during this procedure. Pyridine at a concentration of 10% degraded virions by a different pattern; hexons originating from the faces of the adenovirus icosahedron were preserved in groups of 9. Peripentonal hexons, fibers, degraded vertex capsomers, and low molecular weight antigens were also released. Eight or more antigenically distinct proteins were distinguished as components of the virion; the internal core of the virus, which was retained in a suspended state contained 15% of the total virion protein.

0614 PARTIAL CHARACTERIZATION OF THE COMPLEMENTARY SITES INVOLVED IN THE REACTION BETWEEN ADENOVIRUS TYPE 7 AND ERYTHROCYTE RECEPTORS. (E.) Neurath, A. R. (Wyeth Lab., Philadelphia, Pa.), R. W. Hartzell and B. A. Rubin. *Virology* 42(3):789-793, 1970.

The sites of interaction of adenovirus type 7 and rhesus monkey RBC were partially characterized by *in vitro* incubation with selective enzymes and chemicals. The adsorption of virus to RBC and the hemagglutination by dodecans were independent of pH, indicating that the α-amino groups (α-NH₃⁺) were not essential to the interaction; since carboxypeptidase B (12.5 µg/ml) and leucine aminopeptidase (110 µg/ml) failed to affect the adsorption to RBC, the terminal amino acid residues of the polypeptides were also not necessary to the ad-

VIRAL CARCINOGENESIS

sorption process. Studies with 2,3-butanedione (a reagent that selectively modifies the arginine residues in proteins) showed that the adsorption and hemagglutination abilities of the virus were destroyed in its presence, although addition of the butanedione to already adsorbed adenovirus did not release the virus from the RBC; this suggests that the reagent-sensitive groups are part of the binding site of the virus to cell receptors. RBC treated with 1-cyclohexyl-3-(2-morpholinoethyl)-carbodiimide metho-*p*-toluenesulfonate (CMC, a reagent that selectively modifies carboxyl groups in proteins) exhibited diminished adsorption capacities to adenovirus (although influenza virus remained agglutinable, indicating that neuraminic acid residues were not altered). RBC already adsorbed to adenovirus were released with CMC treatment, suggesting that the adsorbed virus did not protect the cell receptor sites. The reversible interaction of adenovirus type 7 with RBC receptors apparently requires nonterminal arginine residues in the virus and β - or α -carboxylic acid residues in the RBC membrane protein.

- 0615 TRANSFORMATION OF HAMSTER CELLS BY VARIANTS OF PARA-ADENOVIRUS 7 ABLE TO INDUCE SV40 TUMOR ANTIGEN IN THE CYTOPLASM. (E.) Duff, R. (Milton S. Hershey Med. Ctr., Pennsylvania St. U., Hershey), F. Rapp and J. S. Butel. *Virology* 42(1): 273-275, 1970.

Cultures of hamster embryo fibroblast cells were exposed to 1 of 3 strains of cytoplasmic hybrid virus (1cT, 2cT, 3cT) SV40 (PARA) and adenovirus type 7 hybrid (SP2) in order to investigate the transformation of the cells by these virus strains (1 ml of virus-containing fluid was adsorbed in 8×10^5 cells). Virus strain 2cT transformed fibroblasts at a frequency 3-6 times greater than the transformation frequency of the other strains (7.0 focus-forming units/plate examined); however, none of the strains transformed cells at a frequency equal to that of the parental SP2 stock of hybrid virus (which transformed at a rate of 10.25-36.25 focus-forming units/plate examined). Fibroblasts transformed by hybrid virus contained nuclear SV40 tumor antigen. A transformed focus of fibroblast was grown as a cell line, and its oncogenic potential was tested by injecting transformed cells s.c. into hamsters; tumors were induced in 6/17 of the hamsters injected.

- 0616 SPECIFIC ANTITUMOR IMMUNITY INDUCED WITH ADENOVIRUS SA7(C8)-INFECTED CELLS IN HAMSTERS. (Rus.) Babakova, S. B. (P. A. Hertsen Res. Inst. Oncol., Moscow, USSR). *Vop Onkol* 16(6):69-73, 1970.

Specific antitumor immunity in hamsters was induced under 3 sets of experimental conditions: I) by i.v. inoculation of adenovirus type SA7(C8)-induced tumor cells (1 ml of a suspension containing 10^6 cells twice and 10^7 cells once at 7 day intervals); II) i.v. inoculation of freeze-thawed tumor

cells (frozen at -70°C and thawed at room temperature) or ^{60}Co -irradiated tumor cells (5000 rad 36.5 min, single dose) once or 3 times as above and III) i.v. inoculation of adenovirus type SA7(C8)-contaminated embryonic fibroblastic cell cultures (1 ml of suspension containing 5×10^6 cells for 3 times). Antitumor immunity was tested by challenge with a s.c. transplant of a tumor producing amount of SA7 or SV-40 virus induced tumor cells. Specific antitumor immunity was obtained by inoculation with SA7(C8) adenovirus-transformed cells, with irradiated tumor cells and with virus-contaminated cell tissue cultures; no such immunity was produced by freeze-thawed tumor cells. The data seem to indicate the presence of a specific virus-induced transplantation antigen within transformed or contaminated cells.

- 0617 INTERACTIONS BETWEEN SENSITIZED LYMPHOCYTES AND ADENOVIRUS-12-INDUCED TUMOR CELLS. (E.) McDougall, P. T. (Baylor Coll. Med. Houston, Tex.), G. L. Van Hoosier, Jr. and J. Trentin. *Tex Rep Biol Med* 28(1-2):75-86, 1970.

Hamsters were administered increasing sensitive doses of 4-6 i.p. injections of cells derived from adenovirus type 12 tumors, or of cell suspensions prepared from primary or transplant hamster tumors induced by adenovirus type 12; thereafter, sensitized hamsters were killed, and spleen cell preparations were made to determine whether spleen lymphoid cells from immunized animals exert a detrimental effect on the growth of adenovirus-12 induced tumor cells in newborn hamsters. The growth of tumor cells was inhibited when inoculated together with spleen cells from immunized animals, shown by a decreased percentage of tumor take, by a delay in time of appearance of tumors subsequent to inoculation. Of 9 animals inoculated with only tumor cells and 2 animals inoculated with tumor cells plus normal spleen cells, all developed tumors in 20-25 days; of 8 animals inoculated with tumor cells plus immune spleen cells, only 3 developed tumors within 20-25 days and after 8 weeks one other hamster also developed tumors. No antitumor activity of sensitized spleen cells against adenovirus-induced hamster tumors was observed *in vitro*.

- 0618 IMMUNOLOGICAL ANALYSIS OF HAMSTER SARCOMA INDUCED BY ADENOVIRUS TYPE 12. (Rus.) Bashkaev, I. S. (P. A. Herzen Res. Inst. Oncol., Moscow, USSR), A. I. Ageenko and E. Sh. Vardosanidze. *Vop Onkol* 16(7):60-61, 1970.

Immunodiffusion methods revealed 3 distinct precipitin arcs for antigens contained in adenovirus-12-induced hamster sarcoma: 1 arc was in the region of fast α_1 -globulin and 2 arcs were in the region of γ -globulins. The antigens of the first arc and one of the γ -globulin regions were serologically identical to the normal lung tumor antigens; the other antigen of the γ -globulin region was a specific sarcoma tissue antigen. The arcs noticed in the β -globulin region were

identified. The difference between the normal lung tissue antigen and the antigen of the sarcoma tissue seemed to be a quantitative rather than a qualitative one, possibly associated with the activation of certain parts of the cell gene during virus-induced tumorigenic transformation.

- 0619 MORPHOLOGICAL CONFIRMATION OF THE HERPES NATURE OF A CARCINOGENIC VIRUS OF PRIMATES (HERPES SAIMIRI). (E.) Morgan, D. G. (U. Bristol Med. Sch., England), M. A. Epstein, B. G. Achong and J. V. Melendez. *Nature* 228(5267):170-172, 1970.

Confluent owl monkey kidney cell cultures were infected with sufficient virus tentatively designated *herpes saimiri* to produce moderately widespread cytopathic change; infected cells were prepared for electron microscope examination in order to classify the virus definitively. All the infected cultures contained profuse virus particles of herpes-type morphology. In thin sections immature hexagonal particles, either empty or with central ring-shaped or dense nucleoids and of about 108 nm diameter, were seen in both nuclei and cytoplasm. Mature particles with an additional enveloping membrane measured 140 nm across and lay in the perinuclear space, in cytoplasmic spaces or close outside the cell surface. Morphologically, *Herpes saimiri* appears to be a member of the herpesvirus group.

- 0620 CELLULAR CHANGES OF NORMAL HUMAN CERVICAL EPITHELIUM INFECTED *IN VITRO* WITH HERPESVIRUS HOMINIS, TYPE TWO (HERPES SIMPLEX). (E.) Albanks, G. D. (Rush Med. Coll., Chicago, Ill.), J. A. Campbell and L. A. Kaufmann. *Acta Cytol* 14(4):538-543, 1970.

Cellular changes of normal human cervical epithelium were observed with time lapse cinematography after infection *in vitro* with herpesvirus hominis, type two (herpes simplex) obtained from lesions of a patient with genital herpes. The first changes observed (after 6-8 hr) in the infected cells were clumping of nuclear chromatin at the nuclear membrane, disappearance of the nucleoli, and an increase in the density of the cytoplasm. Then certain cells showed a cytoplasmic decrease and slowing movements of the cell membrane and cytoplasmic organelles, and finally fused into a multinucleated giant cell (polykaryosome). The similarity of these changes with those observed in Papanicolaou smears from patients with genital herpes suggests that the smear technique can be used for diagnosis of genital herpes and for investigation of a possible correlation between these infections and cervical cancer.

- 0621 CHARACTERIZATION OF THE DNA OF HERPESVIRUSES ASSOCIATED WITH LUCKE ADENOCARCINOMA OF THE FROG AND BURKITT LYMPHOMA OF MAN. (E.) Wagner, E. K. (Dept. Microbiol., U. Chicago, Ill.), B. Roizman, T. Savage, P. G. Spear, M. Izell, F. E. Durr and D. Sypowicz. *Virology* 42(1):257-261, 1970.

DNA was extracted from herpesvirus preparations obtained from a Lucke adenocarcinoma of the frog and Epstein-Barr virus. The frog virus was found in both nuclear and cytoplasmic cellular fractions, appeared to possess 162 capsomeres, and had DNA with a buoyant density of 1.703 g/cm³. DNA purified from human Burkitt's lymphoma herpesvirus showed 3 density pools of 1.716 g/cm³, 1.716 g/cm³ in 2 different centrifuge bands, and 1.695 g/cm³ in 2 centrifuge bands. Approximately 1/3 of the DNA from Burkitt's tumor virus had a density characteristic of human cell DNA and is assumed to be of host origin; the other 2/3 of the DNA had a density of 1.716-1.718 g/cm³ which corresponds to 57-58 mole% of guanine and cytosine and appears to be of viral origin.

- 0622 HERPETIC INCLUSIONS IN THE ENDOMETRIUM. (E.) Goldman, R. L. (Community Hosp., North Hollywood, Cal.). *Obstet Gynec* 36(4):603-605, 1970.

A 29 yr-old woman presenting with probable missed abortion showed evidence of herpesvirus infection of the endometrium. The association of the infection with apparent abortion suggests that infection of the placenta may have resulted from a prior infection of the endometrium. In view of the increasing evidence for a correlation between carcinoma of the cervix and herpesvirus infection, the finding of herpesvirus infection in still another potential site of neoplasia is noteworthy.

- 0623 IMMUNOFLUORESCENT DETECTION OF HERPESVIRUS ANTIGENS IN EXFOLIATED CELLS FROM THE HUMAN CERVICAL CARCINOMA. (E.) Royston, I. (Stanford U. Hosp., Calif.) and L. Aurelian. *Proc Nat Acad Sci* 67(1):204-212, 1970.

Direct and indirect immunofluorescent examination was performed on exfoliated cells from patients with squamous carcinoma of the cervix; exfoliated dyskaryotic cells from patients with invasive and preinvasive cervical carcinoma were found to contain antigens related to those found in cells infected with herpes simplex virus, type 2. Normal squamous cells from the same subjects and from controls without the disease, as well as cells from mammary carcinoma and endometrial carcinoma did not react with anti-herpesvirus subtype 2 serum. No reaction with the exfoliated cells was demonstrated by antisera to adenovirus type 18 or by *Mycoplasma orale*.

- 0624 HERPESVIRUS-TYPE-2 ANTIBODIES AND CARCINOMA OF THE CERVIX. (E.) Rawls, W. E. (Baylor Coll. Med., Houston, Tex.), K. Iwamoto, E. Adam, J. L. Melnick. *Lancet* 2(7683):1142-1143, 1970.

The incidence of antibodies to venereally transmitted herpes virus type 2 in women with invasive cervical cancer and with cervical carcinoma *in situ*

was investigated. Ninety-six patients and 42 control subjects from New Zealand were examined; 31% of the patients with invasive cervical cancer and 32% of the patients with carcinoma *in situ* were found to have virus antibodies in their sera, as opposed to 23% of controls. These findings conflict with reported incidences of 78-100% antibody-positive invasive cervical carcinoma cases reported in other studies. The data suggest differences in the rate of progression from *in situ* carcinoma to invasive carcinoma, and the variations are perhaps associated with differing sexual practices in the tested populations.

- 0625 NASOPHARYNGEAL CARCINOMA (NPC): I. TYPES OF CULTURES DERIVED FROM TUMOR BIOPSIES AND NON-TUMOROUS TISSUES OF CHINESE PATIENTS WITH SPECIAL REFERENCE TO LYMPHOBLASTOID TRANSFORMATION. (E.) De-The, G. (Ctr. Internat. Res. Cancer, Lyon, France), H. C. Ho, H. C. Kwan, C. Desgranges and M. C. Favre. *Int J Cancer* 6(2): 189-206, 1970.

Cell cultures obtained from biopsy specimens of Chinese nasopharyngeal carcinomata were of 4 types: 26% of biopsies produced epithelial growth of short duration (4-12 wk) and of limited extent around the explants; 70% of cultured biopsies produced early lymphocytic production which lasted from 1-3 wk; 76% of cultures produced fibroblastic cultures, either as primary or secondary to the epithelial growth; 28% of cultures exhibited lymphoblastoid transformation resulting in the establishment of long-term, free-floating cell-lines. Most of these latter lines were independent; however, a few were intermittently dependent on the presence of fibroblasts during crises. Biopsy specimens from head and neck tumors other than nasopharyngeal cancer, from hypertrophied and inflamed tonsils removed from children, and from apparently tumor-free nasopharyngeal mucosa gave rise to a similar spectrum of cultures, including the establishment of long-term lymphoblastoid cultures. In 3 out of 4 cases which underwent transformation, the Henle titer of the corresponding sera was low. The various lines thus obtained exhibited the presence of a herpes-type virus. The establishment of permanent lymphoblastoid lines was probably due to the presence, in the original material, of a herpes-type virus with transforming properties. Although there is no evidence to support the hypothesis of a direct causal relationship between herpes-type virus and nasopharyngeal cancer, an indirect causal relationship may exist between them, whereby the virus acts in synergy with environmental carcinogens.

- 0626 ISOLATION AND PROPAGATION OF A VIRUS FROM A SPONTANEOUS MAMMARY CARCINOMA OF A RHESUS MONKEY. (E.) Jensen, E. M. (John L. Smith Mem. Cancer Res., Maywood, N.J.), I. Zelljadt, H. C. Chopra and M. M. Mason. *Cancer Res* 30(9):2388-2393, 1970.

A virus which was detected in a spontaneous mammary carcinoma of a rhesus monkey was isolated, and prop-

agated in various tissue cultures for the purpose of preliminary characterization. The virus particles were morphologically similar to known oncogenic RNA-type viruses. Initial isolation was effected by cocultivation of tumor tissues with monkey embryo cell cultures; however, it was later found that the virus was transmissible as a cell-free filtrate. The virus was approximately 100 mμ in diameter and had a buoyant density between 1.14 and 1.16. Preliminary host range studies showed that the virus replicated in rhesus monkey mixed embryo, embryo lung, chimpanzee lung, and human mixed embryo cell cultures, and in an established human leukocyte culture. The virus did not replicate when introduced into baboon or chimpanzee leukocyte cultures, hamster kidney, mouse bone marrow, or rhesus or African green monkey kidney cells.

- 0627 GENETIC TRANSMISSION OF VIRUSES THAT INDUCE MAMMARY TUMOR IN MICE. (E.) Bentvelzen, J. (Organization Hlth. Res., TNO, Rijswijk, Netherlands), J. H. Daams, P. Hageman and J. Calafat. *Proc Natl Acad Sci* 67(1):377-384, 1970.

Three strains of untreated mice (Gr, C3Hf and BALB/c) and 2 strains of mice pretreated with irradiation (urethane 020 and C57BL) were infected with mammary tumor virus to investigate the genetic transmission of these viruses. In general, the viruses were transmitted vertically by the gametes of the mouse strain in which they naturally occurred. The virus was present in every cell, although often in an incomplete form. If a mammary tumor virus was introduced into a different mouse strain, only milk-borne transmission occurred, after which the virus was found in a limited number of tissues. Mammary tumor viruses may be transmitted as genetic factors of the host strain to which they belong. A repressor, produced by a regulator gene, appears to control the rate of release of such a genetically transferred virus. Repression can be abrogated by a carcinogenic treatment. The repressor would interfere with the replication of a superinfecting mammary tumor virus.

- 0628 MAMMARY TUMORIGENESIS IN SPLENECTOMIZED MICE. (E.) Squartini, F. (U. Pisa Med. Sch., Italy) and G. B. Bolis. *Texas Rep Biol Med* 28(1-2):115-121, 1970.

Female mice of BALB/cf(C3H) and RIII strains were subjected to splenectomy, thymectomy, both operations, or no operation to investigate the effect of splenectomy on mammary tumorigenesis in mice carrying spontaneous mammary tumor virus infection. In BALB/cf(C3H) females, neonatal splenectomy decreased both the incidence and age of onset of mammary tumors from 82% to 52%, and by an average of 102 days, resp. Thymectomy decreased the incidence of mammary tumors (46%) and increased the age of onset by an average of 130 days; splenectomy of previously thymectomized females partially suppressed the effect of thymectomy and restored the pattern of tumor development to that seen in intact controls. No significant effect was noted on mammary tumor

nesis in RIII mice undergoing splenectomy alone associated with thymectomy.

- 29 MAMMARY-TUMOR VIRUS ACTIVITY IN BRAIN AND LIVER OF GR STRAIN MICE. (E.)
ntvelzen, P. (Netherlands Cancer Inst., Amsterdam) and J. H. Daams. *Europ J Cancer* 6(9):273-276, 1970.

11-free extracts of liver and brain of mice (GR strain) carrying mammary tumors induced by mammary tumor virus were injected i.p. into young BALB/c mice (0.5 ml/mouse), and blood from tumor-bearing mice was similarly injected into test mice (0.1 ml/mouse), to investigate the incidence of tumors in injected mice of various strains. Only 1 out of 81 inbred-bred mice of the BALB/c strain developed a mammary tumor before attaining 1 yr-of-age in control animals, but extracts from livers and brains induced 35 and 29% mammary tumors, resp., in these mice. Brain and liver extracts from other mouse strains which carry mammary tumor virus (C3H strain, BALB/cfC3H strain, and BALB/cfGR strain) caused no tumors. Whole blood of mammary tumor virus-carrying mouse strains BALB/cfC3H and BALB/cfGR induced mammary tumors in recipient mice (tumor incidence 75-90%), while blood from virus-carrying strain mice caused only 25% tumor incidence. Liver, brain and blood of virus-carrying GR mice appears to contain a biologically active form of the mouse mammary tumor virus.

- 30 VIRUS PARTICLES IN A TRANSPLANTABLE RAT MAMMARY TUMOR OF SPONTANEOUS ORIGIN. (E.)
opra, H. C. (John L. Smith Mem. Cancer Res., Wywood, N. J.), A. E. Bogden, I. Zelljadt and E. M. Jensen. *Europ J Cancer* 6(9):287-290, 1970.

Male rats were implanted with grafts from a transplantable adenocarcinoma derived from a spontaneous mammary fibroadenoma; graft slices (10 x 10 x 1 mm) were implanted s.c. in the supra-scapular and/or supra-sacral regions, and an electron microscopic search for virus particles was undertaken in the resultant tumors. C-type virus particles measuring 50 mμ were observed. When virus particles were propagated in tissue culture, the cells replicated C-type particles at a greater frequency than the original tumor cells had. Sucrose-density gradient centrifugation of the particles from tumor as well as from tissue culture yielded a large number of virus particles at a buoyant density of 1.14-1.18 g/cm³.

- 31 STRAIN C3H-A^{VY}fB MICE: NINETY PERCENT INCIDENCE OF MAMMARY TUMORS TRANSMITTED EITHER PARENT. (E.) Vlahakis, G. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), W. E. Ston and G. H. Smith. *Science* 170(3954):185-187, 1970.

After nursing and hybridization experiments were performed with strain C3H-A^{VY}fB mice, which are highly susceptible to mammary tumors (incidence approaching 90% by 15 months-of-age), to determine

whether this susceptibility is transmitted in milk via a mammary tumor virus, or in factors transmitted at conception. Reciprocal matings were effected between the susceptible strain of mice, and a strain having a low incidence of mammary tumors. In addition, low-incidence mice were nursed by high-incidence females, to investigate the possibility of milk transmission of a mammary tumor viral agent. The result of reciprocal hybridization between susceptible C3H-A^{VY}fB mice and less susceptible mice gave no evidence of a maternally transmitted agent implicated as the cause of a high incidence of mammary tumors in the former strain; there was a high tumor incidence in both reciprocal groups (highest incidence in the F₁ generation, 96.3%, lowest, 57.9%). There was no evidence of a mammary tumor virus transmitted to unsusceptible mice in the milk of susceptible nursers; tumor incidence in unsusceptible mice so nursed was only 7.7%. It may be that the factor responsible for a high incidence of mammary tumor in C3H-A^{VY}fB mice is the A^{VY} gene, which may increase the virulence or transmissibility of a variety of mammary tumor virus transmitted vertically by either parent.

- 0632 PRESENCE OF A, B AND C VIRUS-LIKE PARTICLES IN ORGANS OF R111/Dm/Se MICE. (It.)
Bucciarelli, E. (Dept. Res. Cancer, U. Perugia, Italy), G. B. Bolis and F. Squartini. *Lav. Anat. Pat. Perugia* 30(2):57-72, 1970.

Electron microscopic investigations of the distribution of viral particles were made in various organs (mammary gland, epididymis, spleen, thymus, bone marrow and lymph nodes) of R111/Dm/Se female and male mice in the following conditions: one 15-month-old virgin female; two 8-month-old lactating females (3rd pregnancy); 7 multiparous females; one 14-month-old leukemic female; and 6 normal males (8-15 month-old). Four types of viral particles were observed: intracisternal A-type particles, C-type particles (leukemia virus), cytoplasmic A-type particles and B-type particles (MTV). The intracisternal A-type particles were present in most of the organs of normal male, normal and leukemic or mammary gland tumor-bearing female mice; larger amounts were found in the thymus, spleen, marrow and lymph nodes of normal males and leukemic females. C-type particles occurred frequently but never in large amounts in the thymus, spleen and lymph nodes of the leukemic virgin female, the normal males, and the tumor-bearing females as well as in the nipples of lactating females. The cytoplasmic A-type particles were found in the lactating nipples, the mammary gland tumors and the epididymal tissues and were constantly associated with B-type particles in the epithelial cells of these tissues. The presence of cytoplasmic A particles in the thymus, spleen and lymph nodes suggested a possible direct replication of MTV in the lymphopoietic organs; this hypothesis was supported by the bud-like accumulations of these particles in the spleen and lymph nodes of mammary gland tumor-bearing animals, resembling the early stages of development of the B particles.

- 0633 STUDIES ON DDD MOUSE WITH SPECIAL REFERENCE TO MAMMARY GLAND TUMORS. (E.) Matsuzawa, A. (Inst. Med. Sci. U. Tokyo, Japan), T. Yamamoto and K. Suzuki. *Jap J Exp Med* 40(3):159-181, 1970.

The incidence of mammary tumors in virgin mice of the DDD strain, the association of viruses with these tumors, and the tumor-bearing status of pregnant and multiparous mice were studied together with other factors implicated in mammary tumorigenesis. Mammary tumors reached maximum development in virgin mice at the age of 6 months, and atrophic changes in these tumors coincided with decreases in the hormone-producing components of the ovaries. Mammary hyperplastic nodules (averaging 2 in number) were found in virgins above 9 months of age with nodules becoming abundant by 15 months. Hyperplastic nodules could be induced by hormonal stimulation (estrogen + deoxycorticosterone) in 5-wk-old mice. Mammary plaques were rare; however, the mice were found to harbor mammary tumor virus and to transmit it to offspring via breast milk. Mammary tumors and neoplasms of reticular tissue occurred at a mean age of 16.4 months in 34.4% of 67 virgin mice. In 2 force-bred strains mammary tumors developed at an incidence of 71.5 and 90%. Mammary tumor virus appeared to be weakly oncogenic in DDD strain mice but strongly oncogenic in strain BALB/cJms mice. All mammary tumors developed were adenocarcinomas.

- 0634 MECHANISM OF CARCINOGENESIS BY RNA TUMOR VIRUSES: I. AN RNA-DEPENDENT DNA POLYMERASE IN MURINE SARCOMA VIRUSES. (E.) Green, M. (St. Louis U. Sch. Med., Mo.), M. Rokutanda, K. Fujinaga, R. K. Rey, H. Rokutanda and C. Gurgo. *Proc Nat Acad Sci* 67(1):385-393, 1970.

Two murine sarcoma viruses were isolated from virus-infected mice and subjected to DNA polymerase assay procedures, with the result that an active and stable DNA polymerase was identified. Treatment of virus preparations with a nonionic detergent (0.01% Nonidet P-40) was necessary for the detection of enzyme activity. The incorporation of labeled thymidine triphosphate required all 4 deoxyribonucleoside triphosphates and either Mg or Mn ion. Enzyme activity was proportional to virus concentration and was linear with time up to 90 min. The pH optimum for the enzyme was 8.1, and maximal activity was seen at 37°C. The reduction in polymerase activity upon treatment of murine sarcoma virus with RNase, and the absence of detectable amounts of DNA in the virus suggested that the template was RNA. All 4 deoxyribonucleoside triphosphates were incorporated into an acid-insoluble product which was stable in alkali destroyed by DNase, sedimented in alkaline sucrose gradients with a sedimentation coefficient of 7 S, and banded in isopycnic CsCl gradients with a mean buoyant density of 1.700. These findings indicate that the product of the enzyme is DNA.

- 0635 IMMUNITY TO MURINE SARCOMA VIRUS (MSV)-INDUCED TUMORS DEMONSTRATED BY *IN VIVO* ELIMINATION OF ⁵¹CHROMIUM LABELED TUMOR CELLS. Burstein, N. A. (Massachusetts Gen. Hosp., Boston). *Europ J Clin Biol Res* 15(8):873-875, 1970.

Immunity to murine sarcoma virus (MSV)-induced tumors (⁵¹chromium-labeled) in female mice pretreated with Moloney leukemogenic virus (MLV) or a Rauscher pseudotype murine sarcoma virus [MSV(RLV)], Rauscher leukemogenic virus (RLV), or irradiated XM-1 tumor cells was studied by determining the ⁵¹chromium label in the spleens. Treatment of mice with MSV(MLV), or irradiated XM-1 tumor cells prior to challenge with the ⁵¹chromium-labeled tumor cells decreased the radioactivity in the spleen to 67-74% of the nonimmunized control value, while RLV or MSV(RLV) pretreatment did not alter the radioactivity retention. The decreased retention of radioactivity by the spleen paralleled the resistance to tumor cell transplantation suggests this method as an *in vivo* rapid screening technique.

- 0636 CONTROL OF MULTIPLICATION OF UNINFECTED MOUSE EMBRYO FIBROBLASTS AND MOUSE EMBRYO FIBROBLASTS CONVERTED BY INFECTION WITH MURINE SARCOMA VIRUS (HARVEY). (E.) Kotler, M. (Hadasa Sch. Hebrew U. Jerusalem, Israel). *Cancer Res* 30(10):2493-2496, 1970.

Cultures of mouse embryo fibroblasts were infected with murine sarcoma virus (MSV, 5 X 10⁵ focus forming units/ml cells) in order to observe the effect on cell multiplication of virus infection. Cells were treated with calf serum in amounts of 0 or 2% in a modified Eagle's medium. Starting 3 days after infection, the medium was changed daily and every second day some cells were harvested, and the relative population densities were determined. The uninfected cells multiplied to a limited extent in medium containing 0 or 0.5% serum. However, in medium containing 2%, the uninfected and MSV-infected cells multiplied at the same rate, and in medium containing 0.5% calf serum, the murine sarcoma-infected cells multiplied at a higher rate than the uninfected fibroblasts. Apparently, the cells formed by MSV produced some factor or factors which inhibits cell multiplication.

- 0637 MOLONEY STRAIN MURINE SARCOMA VIRUS (MSV-M)-INDUCED TRANSPLANTABLE OSTEOGENIC SARCOMA IN OSBORNE/MENDEL RATS. (It.) Ribbaudi, P. (Dept. Res. Cancer, U. Perugia, Italy). *Laboratory Pathology* 30(2):101-112, 1970.

Inoculation of Moloney Leukemia virus (MLV) at birth) to homozygous Osborne/Mendel rats followed by intracerebral inoculation of murine sarcoma virus (MSV-M), 10 days later, induced spinal osteosarcomas with pulmonary metastases as

the autopsy of a 273 day-old rat. The presence of large amounts of giant polynuclear cells at the peripheral regions of the neoplasm seemed to indicate the transformation effects of the viral agents inhibited on osteoclasts. Cell fragments of such neoplasms exhibited rapid growth *in vitro* with the formation of multilayer foci within 3-4 days after passage. Intraperitoneal inoculation of sarcomatous cells to 4-14 day-old syngeneic rats led to the rapid development of tumors and death within 2 months after inoculation. Acellular extracts from tumor tissue cultures and sarcomatous fragments from the first generation of transplants, inoculated into newborn BALB/c mice, produced no tumors 95 days after inoculation.

8 NONPRODUCER CLONES OF MURINE SARCOMA VIRUS TRANSFORMED BALB/3T3 CELLS. (E.)

Johnson, S. A. (Natl. Cancer Inst., Natl. Inst. Health, Bethesda, Md.) and W. P. Rowe. *Virology* 42(1):9-19, 1970.

Cultures of mouse embryo cells (BALB/c) were inoculated with murine sarcoma virus (2×10^5 virus-containing cells/culture dish), and 5 days later cultures were assayed for murine sarcoma virus. One of 20 foci selected at limiting dilution of murine sarcoma virus solution, 18 released both murine sarcoma virus and murine leukemia virus. Two focus-derived lines, however, showed no physical or biological evidence of virus production and contained evidence of antigens of the murine sarcoma-leukemia complex. These lines had altered properties in tissue culture and *in vivo* and were morphologically indistinguishable from virus-releasing murine sarcoma virus-transformed mouse lines. The addition of helper murine leukemia virus resulted in the rescue of the murine sarcoma virus genome from the host range and neutralization characteristics of the murine leukemia virus used to rescue. These findings indicate that virus production and release is not necessary for the maintenance of the transformed state in mouse cells and may suggest that murine sarcoma virus is capable of initiating transformation without murine leukemia virus. The sarcoma genome could be passed from parent to daughter cell for more than 100 generations in the nonproducer lines, in the absence of any detectable virus expression.

9 INHIBITION OF ONCOGENICITY OF MURINE SARCOMA VIRUS (HARVEY) IN MICE BY INTERFERON. (E.)

Man, L. D. (Boston City Hosp., Mass.). *Nature* 228(5265):1349-1350, 1970.

2-week old mice received i.p. injections of 0.1 ml of Harvey strain murine sarcoma virus, and, in some cases, a subsequent course of interferon injections (2 ml for 30 days), to test the effect of interferon administration on tumorigenesis. Interferon treatment produced a marked delay in mortality, with treated mice surviving for 20 wk postinfection (controls not treated with interferon died within 7 days

after infection with the virus.) Autopsy of treated and untreated mice revealed the erythroblastic splenomegaly and discrete peritoneal sarcomata characteristic of disease produced by Harvey murine sarcoma virus.

0640 THE REPRODUCTIVE AND CELL-TRANSFORMING CAPACITIES OF AVIAN SARCOMA VIRUS B77: INACTIVATION WITH UV LIGHT. (E.) Toyoshima, K. (Res. Inst. Microbial Dis., U. Osaka, Japan), R. R. Friis and P. K. Vogt. *Virology* 42(1):163-170, 1970.

A strain of avian sarcoma virus (Bratislava 77) was isolated from a virus-producing rat cell line subjected to UV irradiation to investigate the ability of UV-irradiated viruses to reproduce and to transform cells. Following UV-irradiation, 2 classes of radiation-damaged survivor virus particles were detected. The ability to release free virus from foci formed by UV-irradiated survivors was also impaired even in the presence of an avian leukosis virus helper. During 5-8 transfers of foci from these survivors a gradual disappearance of transformed cells from the culture was observed, indicating that there may have been a reversion to normal cell morphology due to death of transformed cells. The second class of particles could not transform cells, but produced pseudotypes with a strain of Rous sarcoma virus, interfered with avian sarcoma viruses of subgroup C, and was antigenically identical to the original strain of irradiated virus.

0641 LIGHT INACTIVATION OF FOCUS FORMATION BY CHICKEN EMBRYO FIBROBLASTS INFECTED WITH AVIAN SARCOMA VIRUS IN THE PRESENCE OF 5-BROMODEOXYURIDINE. (E.) Boettiger, D. (McArdle Lab., U. Wisconsin, Madison) and H. M. Temin. *Nature* 228(5272):622-624, 1970.

The effect of visible light on focus formation by chicken embryo fibroblasts (stationary cultures) infected with avian sarcoma virus (B77 or Schmidt-Ruppin) in the presence of 5-bromodeoxyuridine (5BUdR, 2-500 $\mu\text{g}/\text{ml}$) was studied after replating on a feeder layer of rat cells (resistant to infection). Cells infected with 8×10^4 focus forming units (f.f.u.)/cell and exposed to visible light (30 min) in the presence of 5BUdR exhibited an inactivation of focus formation to 5% of the control level (^3H -5BUdR studies showed that only 1% of the incorporated 5BUdR was associated with RNA, suggesting that sensitization to this reagent is a direct result of DNA incorporation). Autoradiographic and cell counting studies showed that the inactivation of focus formation was not a result of cell death or differences in plating efficiencies; focus production in cells infected at 3 f.f.u./cell was more resistant to the inactivation by light (31% survival of foci) than in cells infected at 0.15 f.f.u./cell (6% survival), suggesting that the new DNA is transcribed from viral genes (the increase in viral genes increased the number of copies of the new DNA which increased the resistance to light inactivation).

- 0642 THE INDUCTION OF TUMORS WITH ROUS SARCOMA VIRUS IN MICROTUS AGRESTIS: A PRELIMINARY NOTE. (E.) Smith, C. A. (Imp. Cancer Res. Fund., London, England) and R. J. C. Harris. *Arch Geschwulstforsch* 35(4):299-307, 1970.

Rous sarcoma virus in a 50% mince prepared from chick sarcoma was inoculated s.c. in amounts of 10^5 plaque-forming units in newborn field voles, and induction of tumors was observed after 8 months. Tumor induction appeared to be dependent on the amount of inoculum received, with 51 sarcomas induced in voles receiving 0.05 ml of inoculum, and 64 sarcomas induced in voles receiving 0.1 ml of inoculum. Half of the 41% of the animals which did not develop progressively growing tumors initially developed palpable tumors which then regressed. Cell-free virus rarely induced sarcomata. Seven tumors tested were not virus-producing but 2 of these were virogenic when passaged in association with chick cells. The sarcomas grew poorly in tissue culture and not at all as primary culture in soft-agar, but embryo fibroblast grew well *in vitro*.

- 0643 ROUS SARCOMA VIRUS-INDUCED CHANGES IN URIDINE AND UMP METABOLISM IN CHICK CHORIOALLANTOIC MEMBRANE. (E.) Dodge, W. H. (U. Mississippi Med. Ctr., Jackson), P. A. Morse, Jr. and G. A. Gentry. *Biochim Biophys Acta* 217(1):199-201, 1970.

A strain of Rous sarcoma virus (Fujinami) was inoculated into chick chorioallantoic membrane (10^4 tumor forming units/membrane specimen), and the uridine and/or UMP kinase reactions were investigated 7 days postinfection in the tissue homogenate supernatant. Uridine and UMP kinase were increased in virus infected tissue; a 36-fold increase in phosphorylation rate with the infected supernatant was noted when uridine was the reaction substrate and a 10-fold increase in the infected supernatant when UMP was the reaction substrate. Assay of UMP phosphatase activity revealed no significant difference between the normal supernatant and the infected supernatant fractions, but a 3-fold increase of uridine phosphorylase was found. The increased phosphorylation of uridine and UMP obtained with the infected supernatant fraction appears to be due to increased UMP kinase and uridine kinase and not to a decreased activity of the catabolic enzymes.

- 0644 OVERGROWTH-STIMULATING ACTIVITY OF DISRUPTED CHICK EMBRYO CELLS AND CELLS INFECTED WITH ROUS SARCOMA VIRUS. (E.) Rubin, H. (Dept. Molec. Biol., U. California, Berkeley). *Proc Nat Acad Sci* 67(3):1256-1263, 1970.

The ability of sonically disrupted embryo cells and cells which had been infected with Rous sarcoma virus to stimulate growth of cultured cells was investigated. Sparse (3×10^5 cells/60 mm dish) and dense (3×10^6 cells/60 mm dish) cultures of chick embryo cells were exposed to sonicates of cells from normal crowded cultures or of cells infected

with Rous sarcoma virus. Sonically disrupted cells caused a 6-fold rise in DNA synthesis and cell multiplication (as measured by ^3H -methylthymidine incorporation) when added to the medium of population density-inhibited cultures, but had little effect on the growth rate of sparse cultures. Sonicates from density-inhibited chick embryo cultures had much overgrowth-stimulating activity as did sonicates from actively growing cells. Sonicates of cells infected with Rous sarcoma virus showed a 10-fold increase in overgrowth-stimulating activity 3 days after infection. The activity in Rous sarcoma sonicates returned to near normal amounts at 7 days (^3H -methylthymidine cpm of 9550 and 11,400 for uninfected and infected cells, resp.) concurrently with the appearance of a high content of overgrowth-stimulating activity in the medium. The active overgrowth-stimulating material is nondialyzable. Apparently, rapid growth can be stimulated in density-inhibited cells by the release of some latent overgrowth-stimulating material which is released by sonication.

- 0645 SYNTHESIS OF RNA IN NORMAL AND ROUS SARCOMA VIRUS-INFECTED CELLS: EFFECT OF BROMODEOXYURIDINE. (E.) Levinson, W. E. (U. California Med. Ctr., San Francisco), J. M. Bishop, N. Quintrell, J. Jackson and L. Fanshier. *Virology* 42(1):221-224, 1970.

Gel electrophoresis was employed to examine RNA synthesis in normal and Rous sarcoma virus-infected chick embryo fibroblast tissue cultures which had been treated with bromodeoxyuridine in an attempt to inhibit host RNA synthesis while permitting viral RNA synthesis to proceed unaffected. While the rate of RNA synthesis in virus-infected cells was not affected by exposure to bromodeoxyuridine, normal cell RNA synthesis was reduced by 75% after a 48 hr exposure. Apparently, resistance to bromodeoxyuridine was induced specifically by Rous sarcoma virus. No change in virus replication was observed to follow bromodeoxyuridine treatment; the compound was added to cells 18 hr after infection; when bromodeoxyuridine was added 12 hr after infection, however, the yield of virus was reduced by a factor of 5. Neither infection of cells with Rous sarcoma virus, nor treatment with bromodeoxyuridine had a detectable effect on the rate of cellular RNA synthesis.

- 0646 THE LOW MOLECULAR WEIGHT RNAs OF ROUS SARCOMA VIRUS: I. THE 4 S RNA. (E.) Bishop, J. M. (U. California Sch. Med., San Francisco), W. E. Levinson, N. Quintrell, D. Sullivan, L. Fanshier and J. Jackson. *Virology* 42(1):182-195, 1970.

RNA extracted from purified Rous sarcoma virus was subjected to chromatography on methylated kieselguhr, resulting in the isolation of 4 categories of intravirion RNA including a large component of 4 S RNA, a discrete 7 S component, small quantities of 18 and 28 S RNA, and the 70 S RNA viral genome. The 4 S RNAs of the virus and host cell had identical electrophoretic mobility.

n 10% polyacrylamide gels and were methylated to the same extent. However, significant differences in nucleotide compositions were detectable. The virus apparently did not contain RNA corresponding to any of the other low molecular weight species of cellular RNA. The data were in accord with previous suggestions that RNA tumor viruses contain RNA acquired from the host cell during assembly; but they also suggested at least minor differences in composition between the cellular and viral 4 S RNA populations. That the viral 4 S RNA is not simply a contaminant derived from cellular debris is one conclusion prompted by reconstruction experiment results.

0647 A DNA-DEPENDENT DNA POLYMERASE AND A DNA ENDONUCLEASE IN VIRIONS OF ROUS SARCOMA VIRUS. (E.) Mizutani, S. (McArdle Lab., U. Wisconsin, Madison), D. Boettger and H. M. Temin. *Nature* 228(5270):424-427, 1970.

DNA-dependent DNA polymerase and a DNA endonuclease were identified in Schmidt-Ruppin Rous sarcoma virus by sucrose, cesium chloride, and cesium sulfate gradient analyses. A pronase digested reaction mixture (from a standard polymerase assay) produced a broad peak of 5-16 S material on a sucrose gradient, a peak with a density (g cm^{-3}) of 1.71 on a cesium chloride gradient, and a peak with a density of 1.42 on a cesium sulfate gradient, indicating that the product of the polymerase reaction was short double-stranded DNA (present as early as 1 min after the start of the reaction). Poly dA:dT was more effective as template (5.4-5.95 moles of labeled substrate incorporated) than poly T (0.45-0.47), poly dA (4.3-4.9), or poly rA:dT (0.4-1.85), suggesting that the enzyme preferred an ordered DNA-like structure as template; the better activity (pmoles ^3H -dTTP incorporated) with native *Escherichia coli* or calf thymus DNA (32.2 and 23, resp.) compared to the corresponding denatured DNA (20.2 and 13.2, resp.) confirms that double-stranded template was preferred. Incubation of the whole virion with labeled T7 DNA and subsequent analysis of the T7 DNA on a sucrose gradient revealed the presence of an endonuclease and suggested the possibility of a ligase system in the virion.

0648 DNA POLYMERASES OF ROUS SARCOMA VIRUS: DELINEATION OF TWO REACTIONS WITH ACTINOMYCIN. (E.) McDonnell, J. P. (Dept. Microbiol., U. California, San Francisco), A. C. Garapin, W. E. Levinson, N. Quintrell, L. Fanshier and J. M. Bishop. *Nature* 228(5270):433-435, 1970.

The response of polymerase from Rous sarcoma virus to actinomycin D was used to determine the presence of RNA-dependent and DNA-dependent DNA polymerases. High concentrations of actinomycin D (50 $\mu\text{g/ml}$) inhibited polymerase activity by 55%, and pretreatment of the polymerase mixture with ribonuclease produced a 66% inhibition; the residual DNA synthesis unaffected by actinomycin suggested that polymerase was able to use fragmented RNA as template. Equilibrium density gradients indicated that 2 classes of DNA resulted from

the polymerase reaction: one band was a complex between nascent DNA and viral RNA and was unaffected by the antibiotic; the second was a double-stranded DNA and was inhibited by actinomycin. Repeated sucrose density gradient centrifugations have demonstrated that the actinomycin-sensitive component was an integral part of the virion-associated polymerase and not merely an artifact.

0649 A MUTANT OF ROUS SARCOMA VIRUS (TYPE O) CAUSING FUSIFORM CELL TRANSFORMATION. (E.) Yoshii, S. (Nagoya U. Sch. Med., Japan) and P. K. Vogt. *Proc Soc Exp Biol Med* 135(2):297-301, 1970.

Chick embryo fibroblasts were infected with a virus derived from Rous associated virus which produced some foci with fusiform cell morphology, and this fusiform-transforming virus was subsequently isolated. The fusiform-transforming virus had the envelope properties of a strain of Rous sarcoma virus which causes round cell transformation and had an identical host range producing infections in chicken cells, in Japanese quail cells, and in pheasant cells. Three serum antigens which neutralize the infectivity of the round cell-transforming Rous sarcoma virus also neutralized the infectivity of the fusiform-transforming virus strain at the same titers required for round cell-transforming virus neutralization. Apparently, the fusiform-transforming and round-cell transforming viruses are mutants of the same virus.

0650 ROUS SARCOMA RECURRENCE AND ROUS SARCOMA VIRUS GROWTH IN CHICKEN MUSCLE. (E.) Dinowitz, M. (U. Arizona Sch. Med., Tucson) and H. Rabin. *Int J Cancer* 6(2):160-171, 1970.

Chickens which had been infected with Rous sarcoma virus (RSV), and in which the ensuing tumors had regressed, were re-inoculated with Rous-associated virus at the point of tumor regression (10^5 focus-forming units inoculated) to investigate the mechanism of tumor recurrence. Tumors recurred in one-third of those chickens that received 3 bi-weekly Rous-associated virus injections and in 1 chicken that received only a single Rous-associated virus injection. The tumors re-appeared from 6 to 19 wk after regression of the original tumors and within 4 wk of the last Rous-associated virus challenge. RSV was recovered from cultures of a recurring tumor as well as from a wing that developed subcutaneous blistering following Rous-associated virus inoculations. RSV was also obtained from 40% of "recovered" wing muscles explanted in tissue culture up to 3 months after regression. In addition, RSV was isolated from a tumor that recurred in one of 12 recovered chickens inoculated with Freund's adjuvant. In an attempt to determine if ageing of muscle contributed to resistance to infection and suppression of tumor recurrence, wings of 5-wk-old and 12-wk-old chickens were infected with RSV and Rous-associated virus, or Rous-associated virus alone. RSV and Rous-associated virus were recovered from most muscles explanted 48 hr or more after RSV infection of 5-wk-old chickens. However, when muscles from 12-wk-old

chickens were explanted 4 days after infection, little RSV was recovered, although most of the Rous-associated virus-infected wings produced Rous-associated virus in culture. This suggests that Rous-associated virus growth in older muscles is probably not the limiting factor in RSV growth. It is possible that RSV survived in the muscles of the immune chickens for a prolonged period after tumor regression, and that tumor recurrence was induced by inflammation and recruitment of new susceptible cells by the re-inoculated Rous-associated virus.

- 0651 COMPLEMENTARITY BETWEEN ROUS SARCOMA VIRUS (RSV) RNA AND THE *IN VITRO*-SYNTHESIZED DNA OF THE VIRUS ASSOCIATED DNA POLYMERASE. (E.) Duesberg, P. H. (Dept. Molec. Biol., U. California, Berkeley) and E. Canaani. *Virology* 42(3):783-788, 1970.

The complementarity between an *in vitro* synthesized ^3H -DNA of the Rous Sarcoma virus (RSV)-associated DNA polymerase and Schmidt-Ruppin (SR)-RSV RNA was determined by measuring the buoyant density in cesium sulfate before and after hybridization. ^3H -DNA hybridized with relatively large fragments of viral RNA, and after digestion with RNase the ^3H -DNA was resolved into 2 components with 60-70% at a density of 1.54 g/ml, indicating the amount of 60-70 S SR-RSV RNA hybridizable to ^3H -DNA (the 4 S component of SR-RSV RNA also contained RNA complementary to ^3H -DNA). At saturating concentrations of viral RNA, not more than 50-70% of the DNA hybridized to viral RNA to form DNA-RNA hybrids (the remaining DNA may have the same base sequence as the viral RNA or may have a completely different sequence), while with an excess of the viral RNA up to 75% of the RNA was transcribed to DNA.

- 0652 SARCOMA BLOCKADE *IN VIVO*: RABIES-ROUS SYSTEM IN CHICKENS. (E.) Desai, S. M. (Haffkine Inst., Bombay, India). *Nature* 228(5270):460-461, 1970.

The *in vivo* blockade of Rous sarcoma virus (RSV), determined by the absence of tumor for 21 days and the absence of plasma anti-RSV neutralizing antibody, by a vaccine strain of rabies virus (Semple vaccine) was studied in White Leghorn chickens. The chickens were highly susceptible to RSV (only 2% resistant), but rabies virus (titer of $10^{6.5}$ to $10^{7.2}$ for adult mouse $\text{LD}_{50}/0.03$ ml) given at the same time as RSV or 48 hr later increased the percentage of tumor-free chicks (22% and 44%, resp.) while rabies virus given 24 hr before RSV exhibited no blockade and given 24 hr after RSV exhibited a reduced effect (14%). Increasing the RSV dilution produced a graded increase in the percentage of tumor-free chicks, and the transient nature of the blockade became apparent when tumor-blocked chicks rechallenged with RSV after 30-49 days developed tumors. Anti-RSV neutralizing antibody was not found in tumor-blocked chicks suggesting that Rous associated viruses (RAV-4 and RAV-5) are also blocked.

- 0653 BRAIN TUMORS INDUCED WITH ROUS SARCOMA VIRUS, SCHMIDT-RUPPIN STRAIN: II. R TUMOR SPECIFIC TRANSPLANTATION ANTIGEN IN SUBCUTANEOUSLY PASSAGED MOUSE BRAIN TUMORS. (E.) Kumanishi, T. (Brain Res. Inst., Niigata U., Japan) and T. Yamamoto. *Jap J Exp Med* 40(2):79-86, 1970.

The existence of a Rous tumor specific transplantation antigen was shown in subcutaneously passaged brain tumors (2nd to 10th subcutaneous transplantation generations) which originally had been induced in adult mice with Rous chicken sarcoma cells produced by the Schmidt-Ruppin strain virus. All 4 of the passaged brain tumors studied (C3H-passaged early brain tumor, DDD-passaged early brain tumor, DDD-passaged delayed brain tumor, and CDF₁-passaged delayed brain tumor) exhibited the antigen; all cross-reacted with each other and with 2 lines of long-term passaged (more than 60 transplant generations) ascites sarcoma (SR-C3H/He and SR-DDC₁ ascites sarcoma) which originally had been induced in the subcutaneous region after neonatal inoculation of the same virus. In the immunized animals the tumors developed later, and the sizes of the tumors were always below the range observed in the control animals; the frequency of tumor take was also reduced, and the animals exhibited isograft resistance after 90-270 days of immunization. Mouse brain tumors apparently contain virus-induced tumor specific transplantation antigen which is common to all tumors produced by the same virus but not to chemically induced tumors (methylcholanthrene induced tumors could not be suppressed by simultaneous pretreatment with the Rous virus).

- 0654 FURTHER STUDIES ON TUMOUR-PRODUCING CAPABILITY IN ADULT MICE BY EMBRYONIC TISSUE CULTURES EXPOSED TO A VIRUS AND GRAFTED BEFORE ESTABLISHMENT OF MORPHOLOGIC TRANSFORMATION. (E.) Kryukova, I. N. (Acad. Med. Sci., Moscow, USSR), B. Obukh, T. I. Biryulina and O. V. Babkova. *Cancer* 6(2):275-282, 1970.

Rous sarcoma virus (Carr-Zilber strain) was used to infect embryonic tissue cultures derived from strains A, C3H-H2P, AKR, C57BL/Sn, CC57W, C127, B10.D2, and BALB/c and the infected cells were inoculated into syngeneic ($3-5 \times 10^6$ cells/mouse) to test the oncogenic properties of these cell implants. Mice of strains A, C3H-H2P, AKR, C57BL/Sn, and CC57W developed tumors with an incidence of 100% after latency periods of 4-12 wk. Only 2 of 10 CC57BR mice developed tumors, and no mice of strains B10.D2 or BALB/c developed tumors. However, infected cells originating from resistant mouse strains inoculated into F₁ hybrid mice produced crossing resistant and susceptible mouse strains caused tumors which consisted of cells of the resistant parental strain. Resistance to tumor induction of the 3 strains mentioned above was mediated by the strong immune reaction against the cells introduced. Tumor-production by infected untransformed cells was also seen with the Carr-Zilber strain in hamsters, with the Schmidt-Ruppin strain of Rous sarcoma virus in mice, and with

strain in hamsters but not in mice. No tumors are produced by inoculating mice with syngeneic embryonic tissue culture exposed to a neurotropic strain of influenza A viruses, or SV40.

0655 ANTIGENS OR ROUS VIRUS PARTICLES IN THE VIRUS-FREE TUMORS INDUCED IN ADULT RATS: FACTORS OF CELL AND HUMORAL IMMUNITY. (Rus.)

Uznetsova, N. N. (Acad. Med. Sci. USSR), V. Ya. Nevlyagin and T. I. Biryulina. *Biull Eksp Biol* 70(9):66-69, 1970.

Primary so called "virus-free" tumors, induced in adult Wistar rats by the Schmidt-Ruppin strain of Rous sarcoma virus, were examined for the presence of antigens to Rous virus particles. About 10% of rat Rous tumors had the antigens of virus particles, detected by the fluorescent antibody test. In 17% of the animals tested, the sera had group-specific antibodies detected by the complement fixation fluorescent test. Virus-neutralizing antibodies in the sera of rats were not discovered. About 50% of rats had the cellular immune activity against transplantation antigens of its own "virus-free" tumors. No humoral cytotoxic antibodies could be detected in the sera of rats with Rous tumors; nor was there any correlation of a cellular immune reaction with the presence of group-specific antibodies or antigens of virus particles in these tumors.

0656 CELLULAR IMMUNITY TO ROUS SARCOMA IN TUMOR-BEARING CHICKENS. (E.) Sjogren, H. O.

Dept. Med. Microbiol. Path., U. Lund, Sweden) and Jonsson. *Cancer Res* 30(9):2434-2437, 1970.

Thymus cells of Schmidt-Ruppin Rous virus (RSV-SR)-inoculated chickens bearing Rous sarcomas were tested *in vitro* for colony inhibition (method of Hellström) against the RSV-SR sarcoma cells. The thymus cells from 7 of the 8 RSV-SR inoculated chickens reduced colony formation of the plated Rous sarcoma cells by 20-48% when compared with thymocytes from untreated chickens (even thymocytes from the RSV-SR-treated chickens that had been stored frozen for 3 months maintained their inhibitory activity); thymus cells from the RSV-SR-treated chickens showed no colony inhibition in NIA control tumor, YAA-RC2 sarcoma, or A12B8 adenovirus type 12 tumor, demonstrating the specificity of the inhibitory effect.

0657 NUCLEIC ACID SYNTHESIS DURING THE FOCUS FORMATION BY SHOPE FIBROMA VIRUS ON GREEN MONKEY KIDNEY CELLS. (E.) Takehara, M. (Kobe Sch. Med., Japan). *Arch Ges Virusforsch* 31(3-4):303-312, 1970.

Focus formation and nucleic acid synthesis were studied in African green monkey kidney cells (AGMK) infected with Shope fibroma virus. The AGMK cell cultures were infected with 1-10 plaque-forming U of Shope fibroma virus, and infected and uninfected cultures were labeled with ^3H -thymidine (10 μC /culture bottle). Focus formation was observed as

localized piling up of cells at 3-5 days after viral infection. The number of foci increased in proportion to the size of the Shope fibroma virus inoculum 50 and 160 foci/culture bottle at 2 and 3 virus doses/culture, resp. In the Shope fibroma virus-AGMK cell system, however, the growth rate of virus was comparatively low and no apparent cytopathic effect was demonstrated as a result of virus infection. The incorporation of ^3H -thymidine into the nuclear fraction of infected cells was suppressed early in the cycle of virus replication (from 4 to 0.7 cpm/ μg DNA $\times 10^{-4}$ in 20 hr after virus infection) and before focus formation. On the other hand, the rate of DNA synthesis increased markedly in the infected cytoplasm (from 4 to 9.8 cpm/ μg DNA $\times 10^{-4}$ in 30 hr after viral infection). Accompanying the induction of viral DNA synthesis was a gradual increase in cytoplasmic RNA synthesis.

0658 *IN VITRO* CULTIVATION AND ANTIGENICITY OF COTTONTAIL RABBIT PAPILLOMA CELLS INDUCED BY THE SHOPE PAPILLOMA VIRUS. (E.) Ishimoto, A.

(Aichi Cancer Ctr., Nagoya, Japan), S. Oota, I. Kimura, T. Miyake and Y. Ito. *Cancer Res* 30(10):2598-2605, 1970.

Three cell lines of cottontail rabbit papilloma cells were cultured *in vitro* from cutaneous papillomas induced in rabbits by Shope papilloma virus, and another cell line was established from the skin of a normal rabbit; cytologic properties and antigenicity of these cultures were observed. All 4 cell lines consisted for the most part of spindle-shaped and polygonal cells. Cells from tumor tissue grew at a much faster rate than did cells of the normal rabbit skin, the cell counts on the 8th day of harvest for papillomatous and normal tissue being 340,000 and 110,000, resp. The viral antigen specific for Shope papilloma virus was demonstrated in the cytoplasm of cultured tumor cells by immunofluorescent staining. However, under electron microscopic observation, Shope papilloma virions were not detectable in the cytoplasm or nuclei. On the other hand, tumor-specific T-antigen and surface antigen were clearly demonstrated in the nuclei and on the cell membrane of the tumor cells, resp. These tumor cells were inoculated into domestic rabbits to examine whether the cells retain capacity to produce infectious Shope papilloma virus; no papillomatous growth or tumor development was observed at the site of inoculation in any of these rabbits.

0659 SUSCEPTIBILITY OF HUMAN CELL STRAINS TO TRANSFORMATION BY SIMIAN VIRUS 40 AND SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID. (E.) Aaronson, S. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Virol* 6(4):470-475, 1970.

Early stages in simian virus (SV40) infection were examined to try to elucidate the step or steps responsible for the marked differences in susceptibility of human fibroblasts to transformation by SV40. Human fibroblast cell cultures from patients with genetic diseases, Fanconi's anemia, and Down's syndrome were exposed to SV40 and SV40 DNA. Tumor

antigen induction by SV40 and SV40 DNA was studied in transformation-susceptible, transformation-resistant, and normal cells, with the result that whole virus produced more tumor antigens in susceptible and normal cell types than did SV40 DNA (e.g., 22.0 and 2.1% of tumor antigen-containing cells were produced in susceptible and normal cells, resp., by SV40 DNA). However, in resistant cells SV40 DNA produced more tumor antigen-containing cells than did whole SV40 (e.g., 0.4 and 0.2% tumor antigen containing cells produced by SV40 DNA and SV40, resp.) The most transformation-susceptible cells infected with whole virus exhibited a level of transformation 1800 times in excess of the level exhibited by the most transformation-resistant cells; however, when cells were infected with SV40 DNA, susceptible and resistant cells showed no difference in transformation level. The elimination of the differences in transformation frequency with whole virus among cell strains by SV40 DNA suggests that the relative resistance of most cell strains to transformation is determined at an early step in infection.

- 0660 ANALYSIS OF SV40-INDUCED TRANSFORMATION OF HAMSTER KIDNEY TISSUE *IN VITRO*: VII. INDUCTION OF SV40 VIRUS FROM TRANSFORMED HAMSTER CELL CLONES BY VARIOUS AGENTS. (E.) Rothschild, H. (Harvard Med. Sch., Boston, Mass.) and P. H. Black. *Virology* 42(1):251-256, 1970.

Hamster kidney cell lines transformed by SV40 were exposed to various chemical and physical agents to investigate the yield of infectious virus induced from the hamster cell clones. One inducible line of cells (I_gAP1) was tested with the agents mitomycin C, acriflavine, 5-bromodeoxyuridine, caffeine and UV- and X-irradiation. Although all these agents except acriflavine were able to induce infectious virus from the cell clone, mitomycin C (2 µg/ml) induced the highest yield of virus. The dose of inducing agent and the amount of infectious virus produced were not always proportionally related. No combination of agents was more effective in inducing virus production than each agent used singly.

- 0661 SPECIFIC AGGREGATION OF SV40-TRANSFORMED CELLS BY ORNITHINE, LEUCINE COPOLYMERS. (E.) Duksin, D. (Weizmann Inst. Sci., Rehovot, Israel), E. Katchalski, and L. Sachs. *Proc Nat Acad Sci* 67(1):185-192, 1970.

A copolymer of L-ornithine and L-leucine was added to suspensions of a wide variety of normal and virally and nonvirally-transformed mammalian cells to investigate the agglutinating effect of this peptide on these cells. The basic copolymer studied rapidly agglutinated normal and transformed cells in the absence of serum, while in the presence of 10% calf serum, agglutination was inhibited. This copolymer and those of ornithine and valine and arginine and leucine produced, in the presence of serum, a specific aggregation of simian virus 40-transformed cells cultured for about 24 hr after addition of the peptide. The rapid agglutination and

SV40-specific aggregation could not be inhibited by a variety of individual amino acids or carbohydrates. The specific aggregation could be detected in suspensions of SV40-transformed and other cells, and was not prevented by X-irradiating the cells with 10⁵ r. Aggregation of the SV40-transformed cells was inhibited by acidic polyamino acids provided these were added not later than about 5 hr after addition of the basic copolymer. The results indicate that the basic copolymer, in the presence of serum, produces aggregation in SV40-transformed cells, presumably in the surface membrane, that causes the cells to aggregate. In addition to the aggregation of cells transformed by SV40, cells transformed by adenovirus 12, which do not contain detectable SV40-specific nuclear antigens, were also aggregated by the basic copolymer in the presence of serum. Apparently, SV40-induced changes in the surface membranes of cells transformed by adenovirus type 12 can be detected by the thine-leucine copolymer.

- 0662 THE EFFECT OF ACTINOMYCIN D ON DNA SYNTHESIS IN SV40 INFECTED EXPONENTIALLY GROWING AND STATIONARY CELLS. (Ger.) Fischer, H. (German Cancer Res. Ctr. Heidelberg, Germany). *K. Munk. Z Krebsforsch* 74(4):390-395, 1970.

The effect of actinomycin D (Ac-D) on DNA synthesis in SV40-infected *Cercopithecus* monkey renal cells was investigated by means of immunofluorescence, autoradiography in exponentially growing and stationary cell cultures. Inhibition of DNA synthesis was observed 25 hr after viral infection in the untreated exponentially growing cell cultures; then DNA synthesis resumed. A 30 min treatment with Ac-D (1 µg/ml) 2½-3 hr following SV40 infection of the renal cells led to a 10 hr inhibition of DNA synthesis followed by renewed synthetic processes; 30 hr after infection the number of labeled cells in the Ac-D-treated cultures was the same as that occurring at 45 hr after infection in the nontreated cultures. A decrease of DNA synthesis was noticed 10 hr after viral infection in untreated stationary cell cultures. Ac-D treatment 2½-3 hr after infection induced a further DNA synthesis 15 hr after infection, following a trend similar to that of untreated cells. The enhanced effects of Ac-D on the inhibition and renewal of DNA synthesis in the exponentially growing SV40-infected cells indicate a possible competition between the viral and cellular processes, as observed in the stationary cultures.

- 0663 ENHANCEMENT OF VIRAL TRANSFORMATION BY ULTRA-VIOLET LIGHT. (E.) Lytle, C. (Bureau Radiol. Hlth., Rockville, Md.), K. B. Hellman and N. C. Telles. *Int J Radiat Biol* 297-300, 1970.

The effect of UV irradiation in varying doses on cell susceptibility to transformation by SV40 was investigated. A line of mouse cells BALB/3T3 given UV irradiation in doses ranging from 13 to 130 erg/mm² of cell culture and then infected with virus. The colony-forming ability of the infected cells decreased with increasing UV dose. Total

colony-forming units after 136 erg/mm² UV numbered 1.3×10^5 ; after 544 ergs/mm², total colony-forming units numbered 1.0×10^3 . The appropriate figures for transformed colony units after 136 and 544 ergs/mm² UV were 4.4×10^3 and 1.6×10^2 , resp. Apparently, the fraction of surviving colonies which are transformed increases with UV dose. The UV target for transformation enhancement was apparently smaller than the target for inactivation of colony-forming ability for these cells. The findings seem to indicate that UV radiation is capable of enhancing viral tumorigenesis.

0664 EFFECT OF PROLONGED CULTIVATION OF SV40-TRANSFORMED MOUSE CELLS IN BROMODEOXYURIDINE OR PRETREATMENT WITH MITOMYCIN C ON RESCUE OF SV40. (E.) Dubbs, D. R. (Baylor Coll. Med., Houston, Tex.) and S. Kit. *Int J Cancer* 6(2):223-233, 1970.

The genetic effect of prolonged culturing of primary mouse kidney cells transformed by UV-irradiated SV40 (mKS-U cell lines) with 5-bromodeoxyuridine (10 µg/ml) and the effect of mitomycin C pretreatment (1 µg/ml for 20 hr) on rescue of SV40 were determined. Four of the cell lines grown with 5-bromodeoxyuridine became deficient in thymidine kinase activity [mKS-U3(BU), mKS-U5(BU), mKS-U13(BU), and mKS-U18(BU)] while mKS-U1(BU) and mKS-U2(BU) retained thymidine kinase activity. The thymidine kinase-deficient lines were unable to grow in a medium with hypoxanthine, aminopterin, thymidine, and glycine because of their inability to use the exogenous thymidine as a source of thymidylate when aminopterin blocked the *de novo* synthesis. The bouyant densities in cesium chloride of DNA from the thymidine kinase-deficient lines were normal (1.703 g cm^{-3}) compared to the heavier DNA isolated from the cell lines grown in 5-bromodeoxyuridine which maintained thymidine kinase activity (1.722 g cm^{-3}). The SV40 T antigen was maintained in all the cell lines even after prolonged cultivation with 5-bromodeoxyuridine. Rescue of SV40 from the mKS-U(BU) lines by fusion with CV-1 cells (African green monkey kidney cells) in the presence of UV-Sendai virus after serial passage in 5-bromodeoxyuridine was not altered in the average or good yielder transformed lines, although 2 poor yielders (mKS-U1 and mKS-U3) produced medium-sized and clear infectious plaques after 5-bromodeoxyuridine passage. No SV40 could be rescued from rare or non-yielder lines after serial passage. Pretreatment with mitomycin C before fusion with CV-1 cells did not affect the yield from the good yielder (mKS-U13) and did not permit SV40 rescue from rare or non-yielder lines.

0665 CHROMOSOMES OF SV40 TRANSFORMED HUMAN AMNION CELLS AFTER MYCOPLASMA INFECTION. (E.) Fogh, J. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), H. Fogh and M. Dowling. *Proc Soc Exp Biol Med* 135(2):206-211, 1970.

Primary cultures of human amnion cells were infected concurrently with SV40 and the HT strain of mycoplasma in order to investigate the modifications in chromosome numbers and the frequencies of chromosome

abnormalities related to the presence of mycoplasma in the virus-transformed cultures. Chromosome numbers in cells infected with SV40 had changed to the hypertriploid-hypotetraploid range when examined 145 days after infection; numbers in cells infected with both virus and mycoplasma generally remained in the diploid range up to 207 days post-infection at which time about 50% of cells were in the hypertriploid-hypotetraploid range. In the virus-infected group, there was a gradual reduction in the numbers of chromosomes after the 145th day post-infection, and chromosome abnormalities were generally more frequent than in cells infected with both virus and mycoplasma; the frequency of abnormalities increased with elapsed time post-infection. From 183-242 days post-infection, 96% of virus-infected cells showed di- and polycentric chromosomes, as compared to 77% of virus-and mycoplasma-infected cells. Acentric chromosome fragments occurred in 33 and 13%, resp., of virus-infected and virus- and mycoplasma-infected cells. Percentages of minute chromosomes in the 2 infection groups were 47 and 31%, resp. After mycoplasma elimination, chromosome numbers and aberrations were not reversed, but the occurrence of large telocentric chromosomes was more frequent.

0666 TEMPERATURE-SENSITIVE SIMIAN VIRUS 40 MUTANT DEFECTIVE IN A LATE FUNCTION. (E.)

Kit, S. (Baylor Coll. Med. Houston, Tex.), S. Tokuno, K. Nakajima, D. Trkula and D. R. Dubbs. *J Virol* 6(3):286-294, 1970.

A cell-line of monkey kidney cells was infected with a strain of SV40 (infection multiplicity of 5 plaque-forming units/cell in a 0.2 ml volume) and then treated with the mutagen nitrosoguanidine in doses of 100 µg/ml culture for the purpose of isolating a SV40 mutant which replicated at differing rates in differing temperature conditions. Replication of virus, designated tsTNG-1, at the nonpermissive temperature (38.7°C) was 3,000-fold less than at the permissive temperature (33.5°C). Plaque formation by the mutant strain's DNA on kidney cell culture monolayers occurred normally at 33.5°C but was grossly inhibited at 38.7°C. The time at which virus replication was blocked at 38.7°C was determined by temperature-shift experiments. In shift-up experiments, cultures infected for various times at 33.5°C were shifted to 38.7°C. In shift-down experiments, cultures infected for various times at 38.7°C were shifted to 33.5°C. All cultures were harvested at 96 hr postinfection. No virus growth occurred when the shift-up occurred before 40 hr postinfection. Maximum virus yields were obtained at 96 hr postinfection when the shift-down occurred at 66 hr, but only 15% of the maximum yield was obtained when the shift-down occurred at 76 postinfection. These results indicate that tsTNG-1 contains a conditional lethal mutation in a late viral gene function. The mutant synthesized tumor antigen, viral capsid antigens, and viral DNA, and induced thymidine kinase activity at either 33.5 or 38.7°C. The properties of the viral DNA synthesized in mutant-infected kidney cell culture cells at 33.5° or 38.7°C were very similar to those

of SV40 DNA made in parental virus-infected cells, as determined by nitrocellulose column chromatography, cesium-chloride-ethidium bromide equilibrium centrifugation, and by velocity centrifugation in neutral sucrose gradients. Mutant tsTNG-1 enhanced cellular DNA synthesis in primary cultures of mouse kidney cells at 33.5° and 38.7°C and also transformed mouse kidney cultures at 36.5°C. After fusion with susceptible monkey kidney cell cultures and incubation at 38.7°C, the mutant could not be recovered from a clonal line of transformed cells; however, after incubation at 33.5°C, recovery was possible.

- 0667 EFFECT OF LOSS OF THYMIDINE KINASE ACTIVITY ON THE TUMORIGENICITY OF CLONES OF SV40-TRANSFORMED HAMSTER CELLS. (E.) Rothschild, H. (Massachusetts Gen. Hosp., Boston) and P. H. Black. *Proc Nat Acad Sci* 67(2):1042-1049, 1970.

Characteristics of cells (derived from transplantable SV40-transformed hamster kidney cells) deficient in thymidine kinase (TK⁻) were studied. Wild type cells (TK⁺) incorporated 100 times as much ³H-thymidine (11.0-23.0 x 10³ cpm/10⁶ cells). TK⁺ cells had a large variation in chromosome number (53-114 chromosomes) while TK⁻ cells (T8 BU 1-1) had relatively constant modal numbers (52-54 chromosomes). Tumors initiated by TK⁺ cells appeared in 95% of the animals 2-8 wk after inoculation, while only 1 tumor was observed in hamsters inoculated with TK⁻ cells by the 8th wk. Cells harvested from tumors induced with TK⁻ cells and revertant cell lines (spontaneous or chemically mutated) obtained from TK⁻ cells showed thymidine kinase activity to be intermediate between that of the wild type and the enzyme-deficient cell lines. The thymidine kinase salvage pathway enzyme may play a rate-limiting role in tumorigenesis.

- 0668 EFFECT OF ULTRAVIOLET IRRADIATION ON THE SURVIVAL OF SIMIAN VIRUS 40 FUNCTIONS IN HUMAN AND MOUSE CELLS. (E.) Aaronson, S. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Virol* 6(4):393-399, 1970.

The effect of UV irradiation on viral functions, including transformation ability, tumor-antigen production, and virus-antigen production was investigated; mouse and human cells were exposed to SV40 which had received 24 ergs/mm² culture of UV at wavelengths of 253.7 nm for varying periods of time (5-20 min). Transformation appeared to be less UV-sensitive than either tumor- or virus-antigen when all functions were compared in the same cell. However, the time course of both tumor- and virus-antigen appearance was delayed with UV-irradiated virus, so that the survival curves of these functions changed with time. Mouse and human cells which were transformed by UV-SV40 all contained SV40 antigen. Infectious virus could be recovered from many more transformants than would be expected from the infectivity in African green monkey kidney cells of the irradiated virus. Apparently, UV-damaged SV40 can be reactivated by human and mouse cells.

- 0669 ANTIGENIC STUDY OF UNFERTILIZED MOUSE CROSS REACTIVITY WITH SV40-INDUCED ANTIGENS. (E.) Baranska, W. (Wistar Inst. Anat. Biol., Philadelphia, Pa.), P. Koldovsky and H. Koprowski. *Proc Nat Acad Sci* 67(1):193-199, 1970.

The antigenic properties of a mammalian ovum at earliest stage of development were studied by preparing an anti-egg serum from guinea pigs immunized with unfertilized eggs from virgin C57BL/6. This serum was introduced into preparations of eggs obtained from allogeneic and syngeneic mice, rat eggs, lymph node cells, methylcholanthrene-induced tumor cells, normal mouse embryo cells from syngeneic or allogeneic mice, and SV40-transformed mouse embryo cells. Cytotoxicity and immunofluorescence tests showed that the anti-egg serum was cytotoxic for eggs of mice syngeneic and allogeneic with the donors of the immunizing eggs but not cytotoxic for rat eggs, lymph node cells, methylcholanthrene-induced tumor cells, or normal mouse embryo cells. However, anti-egg serum was cytotoxic for SV40-transformed mouse embryo cells. This cross reactivity between the SV40-transformed cells and mouse eggs was further supported by the elimination of cytotoxicity of the anti-egg serum for mouse eggs after absorption with SV40 transformed cells. Viral transformation may have altered the structure of the embryo cell surface in such a way as to make it sensitive to the anti-egg serum.

- 0670 INDUCTION OF SV40 TRANSPLANTATION ANTIGEN (TrAg) DURING THE LYTIC CYCLE. (E.) Girardi, A. J. (Wistar Inst. Anat. Biol., Philadelphia, Pa.), and V. Defendi. *Virology* 46:688-698, 1970.

The induction of SV40 transplanted antigen (TrAg) in vaccinated hamsters and the inhibition of TrAg production by various agents was investigated. Hamsters were inoculated with a tumor-inducing dose of SV40 (0.2 ml) at birth, and were subsequently given a vaccination injection of SV40-infected African green monkey kidney cells (AGMK) in doses of 10^{7.2} plaque-forming units during the latent period of tumor-induction. The appearance of SV40 TrAg was blocked by (cycloheximide, 20 µg/ml), or by a level of actinomycin D (5 µg/ml) that inhibits early and late viral functions. Antigen induction was not blocked by inhibitors of DNA synthesis (fluorodeoxyuridine, 25 µg/ml) or by a level of actinomycin D (0.5 µg/ml) that ordinarily permits expression of early viral functions. When virus matured in the infected cells in the absence of chemical inhibitors, or after drug withdrawal, yield of infectious virus was not sufficiently high to account for the development of tumor resistance in the hamsters. The ability of infectious SV40 to induce tumor resistance in hamsters was related to the quantity of tumor-inducing virus given to born hamsters: animals given large amounts of virus at birth were refractory toward immunization by even high levels of infectious virus. However, SV40-infected AGMK cells effected immunization of these animals.

- 0671 QUANTITATIVE ASPECTS OF IMMUNIZATION AGAINST PRIMARY SV40-INDUCED TUMORS. (E.) Kaliev, J. (Acad. Med. Sci. USSR, Moscow). *Neoplasma* 17(4):373-376, 1970.

The interruption of SV40-induced carcinogenesis by immunization of infected animals with the same virus during the latent period was studied quantitatively. SV40 preparations were injected s.c. in newborn hamsters in amounts ranging from 1.7×10^6 - 1.7×10^7 tissue culture infectious dose (TCID) of virus; after 3 wk, 50% of hamsters were immunized by i.p. injection 1.2×10^8 TCID of SV40. In a related experiment, newborn hamsters were infected s.c. with 1.5×10^6 TCID of SV40, and subsequently immunized with varying amounts of the virus. Immunization during the latent period before tumor appearance after initial infection significantly inhibited tumor development, with animals receiving the higher infectious dose of virus developing a higher percentage of tumors than animals receiving lower doses of virus (tumor induction of 21% and 10% for high and low dose hamsters, resp.) Mean latent periods before tumor appearance were markedly longer in immunized hamsters than in nonimmunized controls (178 and 115 days for immunized and non-immunized hamsters receiving 1.7×10^7 TCID of virus, resp.) In the second experiment, hamsters receiving immunizing doses of virus developed tumors in 3.3% and 26.7% of cases when injected with 1.2×10^8 and 1.2×10^7 TCID of immunizing viruses, resp., and in 74.4% of cases when no immunizing dose of virus was administered.

- 0672 INVESTIGATIONS ON THE HISTOGENESIS OF LEUKOSIS INDUCED BY SYRIAN HAMSTER PAPOVA VIRUS. (Ger.) Fey, F. (German Acad. Sci., Berlin), T. Schramm, E. Bender and M. Rudolph. *Arch Geschwulstforsch* 36(1):10-18, 1970.

Following the inoculation of hamster papova virus, the induced leukoses of tumor type occur mainly in the liver and thymus. Leukoses with typical enlargement of the lymph nodes and leukotic tumors of the mesentery are less frequent. The histogenesis of leukosis induced by this virus was investigated in the newborn hamster by s.c. injections of 0.2 ml by means of histochemical enzyme reactions. The first pathological change following the inoculation occurred in 4 days showing an atrophy of the thymus, and this change was observed in all the experimental animals until the 18th day after inoculation. Histologically there was a gradual decrease of lymphocytes in the cortical area. Pyknotic lymphocytes and phagocytes were abundant, and the extremely atrophied thymus consisted almost exclusively of reticular cells. A direct virus action upon the livers of newborn hamsters may be related to the fact that as long as 5 days after birth there are areas in the liver of myeloid and erythrocyte formation. It is postulated that the leukocytic tumors become manifest in the vascular areas when infiltration sets in.

- 0673 BEHAVIOR OF TISSUE CULTURE CELLS INFECTED WITH POLYOMA VIRUS. (E.) Dulbecco, R. (Salk Inst. Biol. Stud., San Diego, Calif.). *Proc Nat Acad Sci* 67(3):1214-1220, 1970.

Induction of movement, cell survival, mitotic rates, growth parameters, and cell morphology of tissue culture cells (3T3 and BALB/c-3T3 lines) infected with the oncogenic polyoma virus or its temperature-sensitive mutant (Ts-a) were studied. In medium containing 0.15% horse serum the induction of movement across a wound (produced with a glass rod) occurred simultaneously with the induction of DNA synthesis. Infection with Ts-a protected the cells from death at suboptimal serum concentrations, but there was no difference in cell survival between polyoma virus- or mock-infected cultures. Mitosis decreased in mock-infected cells after 20 hr but persisted in Ts-a-infected cultures. The wound serum requirement and topoinhibition of the mock-infected cells were decreased in polyoma virus-infected and Ts-a-infected cells (60-90%). The flat, round-shaped cells of serum-starved 3T3 or BALB/c-3T3 cultures became thick and elongated after infection, similar to changes that occur in cell transformation.

- 0674 THE SYNTHESIS AND BREAKDOWN OF NUCLEIC ACIDS IN MAMMALIAN CELLS TRANSFORMED BY ONCOGENIC VIRUSES: I. PURIFICATION AND PROPERTIES OF AN ENDONUCLEASE FROM BABY HAMSTER KIDNEY CELLS TRANSFORMED BY POLYOMA VIRUS. (E.) Koh, J. K. (U. Maryland Sch. Med., Baltimore), A. Waddell and H. V. Aposhian. *J Biol Chem* 245(18):4698-4707, 1970.

An endonuclease from a continuous line of baby hamster kidney cells transformed by polyoma virus (BKH21 C13/PyH3) was purified 1000-fold (DEAE-cellulose, phosphocellulose, and hydroxylapatite column chromatography) and characterized. The enzyme (molecular weight of 76,000) hydrolyzed heat-denatured DNA, RNA, and homopolynucleotides; native DNA was not affected. The enzyme appears to prefer polynucleotides which lack ordered structures as substrates, and evidence suggests that the DNase and RNase reside in the same protein. The optimum pH was between 8.7 and 9.5, and Mg^{++} (0.4-0.8 mM) or Mn^{++} (0.04 mM) was required for enzyme activity, while sodium or potassium chloride (10 mM) inhibited the activity by approximately 50%. The products of the hydrolysis of polyadenylate or polydeoxythymidylate were 5'-phosphate-terminated oligonucleotides. A similar enzyme appears to be present in normal baby hamster kidney cells.

- 0675 TRANSFORMATION OF HUMAN CELLS BY POLYOMA AND ROUS SARCOMA VIRUSES MEDIATED BY INACTIVATED SENDAI VIRUS. (E.) Shevliaghyn, V. J. (Gama-leya Inst. Epidem. Microbiol., Moscow, USSR) and N. V. Karazas. *Int J Cancer* 6(2):234-244, 1970.

Transformation of embryonic human fibroblasts was accomplished by polyoma and Rous sarcoma viruses in

the presence of inactivated Sendai virus. Treatment of the human cells with inactivated Sendai virus (hemagglutination titer of 1:40,000) followed by polyoma virus produced a stable transformed cell line, P-2, and treatment with Rous sarcoma virus followed by the inactivated Sendai virus produced a stable transformed cell line, 23. Both transformed cell lines differed morphologically from normal cells and had karyological abnormalities (decreased numbers of chromosomes in groups A and B and increased numbers in group C as well as some marker chromosomes) but contained human chromosome sets. The cell lines P-2 and 23 were able to grow in suspension and produced tumors in the cheek pouches and brains of hamsters, and factors were found in the media of both cell lines that were capable of transforming mouse and human cells.

- 0676 POLYOMA "TUMOR ANTIGEN": AN ACTIVATOR OF CHROMOSOME REPLICATION? (E.) Weil, R. (Inst. Molec. Biol., U. Geneva, Switzerland) and J. Kara. *Proc Nat Acad Sci* 67(2):1011-1017, 1970.

The time and temperature relation between the appearance of T-antigen and the activation of the cellular DNA-synthesizing apparatus was studied by immunofluorescence in contact-inhibited mouse kidney tissue culture cells infected with polyoma virus. The events of the polyoma lytic cycle were essentially the same at 37 C and 27 C although they proceeded at a slower rate at the lower temperature. At 37 C T-antigen was detected in 80-100% of the infected cells after 16-20 hr, and the lag between the appearance of T-antigen and the onset of polyoma-induced DNA synthesis varied from 2-8 hr. At 27 C T-antigen was detected after 50-60 hr, and the lag between the appearance of T-antigen and the onset of DNA synthesis varied from 15-20 hr to more than 3 days. Polyoma-infected cultures incubated at 27 C and transferred to 37 C for a 1 hr incubation before the onset of polyoma-induced DNA synthesis had no more DNA-synthesizing cells than mock-infected cells: when infected cells were transferred to 37 C for more than 3 hr the numbers of DNA-synthesizing cells increased with time. When these cells were transferred to 37 C after the onset of polyoma-induced DNA synthesis, the number of DNA-synthesizing cells increased by a factor of 1.5-2. The early period (time between the adsorption of polyoma virus and the appearance of T-antigen) was increased from 12 hr at 37 C to 30 hr at 27 C, and infected cells incubated at 37 C for 12 hr before transfer to 27 C exhibited polyoma-induced synthesis within 30 hr after infection. However, the kinetics of the increase in DNA-synthesizing cells was similar to cells that had been kept at 27 C throughout suggesting that a "psychrosensitive (time and temperature dependent) event(s) begins only after the early period.

- 0677 POLYOMA VIRUS-TRANSFORMED CELLS; THEIR AGING AND VIRUS GENERATION *IN VITRO*. (It.) Pitzurra, M. (Inst. Microbiol. Hyg., U. Perugia, Italy) and F. Bistoni. *Boll Soc Ital Biol Sper* 46(5):215-218, 1970.

Culture media of a B-line of polyoma virus-transformed cells (69th passage, B69,) consisting of Medium 199 and 10% calf serum were used after 33 days of incubation to test the capability of transformed cells to generate viruses. The medium was added to primary cultures of mouse embryo tissues (0.2 ml of B69) and inoculated into 14 day-old hamsters (0.2 ml B69 i.p. to 8 animals which were sacrificed 62 days later). Control hemagglutination activity was determined with immune anti-polyoma serum obtained from adult male hamsters which were inoculated at birth with 0.4 ml of polyoma virus stock suspension containing 10^8 oncogenic U/ml twice at 20 day intervals and a pool of serum with a hemagglutination titer of 1/12,800 in 0.2 ml was obtained 10 days after the second inoculation. Cytopathic effects occurred 9 days after infection in embryo cultures, and hemagglutination activity appeared in the culture medium supernatant 8 days after B69 inoculation; both effects were transmissible in the culture medium supernatant to similar primary tissue cultures. Tumors occurred in 6 of 8 hamsters 2 months after inoculation. Hemagglutination activity of B69 was completely inhibited by hamster antipolyoma immune serum. B-line cells that were transformed by virus polyoma *in vivo* are apparently able to produce hemagglutinative and infective virus after 30 days of *in vitro* cultivation.

- 0678 INTERFERON-SENSITIVITY OF THE ENHANCED INCORPORATION OF THYMIDINE INTO CELLULAR DNA INDUCED BY POLYOMA VIRUS. (E.) Dulbecco, R. (Salk Inst. Biol. Stud., San Diego, Calif.) and Johnson. *Virology* 42(2):368-374, 1970.

The effect of large doses (100 and 200 U/ml) of purified interferon (produced in L-929 cells with Newcastle Disease virus) on the induction of cellular and viral DNA synthesis by polyoma virus and its Ts-a mutant in 3T3 cells was studied. Interferon (100 U/ml) inhibited ^3H -thymidine incorporation into both viral (64-73% inhibition) and cellular (40-75%) DNA in polyoma-infected cells to similar extent; as it also inhibited label incorporation into cellular (56-62%) DNA in Ts-a-infected cells. ^3H -Thymidine incorporation was also slightly inhibited by interferon in uninfected cells (13%) but this was probably caused by the high doses of interferon used and by its high degree of purity.

- 0679 RESTORATION OF NORMAL GROWTH BY COVERING OF AGGLUTININ SITES ON TUMOR CELL SURFACES. (E.) Burger, M. M. (Dept. Biol. Sci., Princeton U., N. J.) and K. D. Noonan. *Nature* 228(5271):515, 1970.

The efficacy of covering agglutinin sites on virus-transformed cells for restoring normal growth-inhibition patterns to those cells was investigated. Polyoma virus-induced tumor cells (Py3T3) were incubated with trypsinized concanavalin A, and agglutination assays were performed. Preincubation with trypsinized concanavalin A radically increased the amount of agglutinin necessary to bring about

agglutination of cells, with untreated transformed cells requiring 250 µg/ml agglutinin, and normal and concanavalin A-treated cells requiring less than 1500 µg/ml agglutinin. The higher the density of cells in culture treated with concanavalin A, the earlier the onset of growth inhibition occurred, suggesting that the inhibiting effect of concanavalin A covering induced a genuine contact-inhibition effect, rather than a simple prevention of cell growth *per se*. Apparently it is the absence of the layer covering the agglutination site, and not the exposure of the agglutinin receptor layer, which accounts for the loss of contact inhibition of growth in virally-transformed cells.

0 ABSENCE OF A CELL MEMBRANE ALTERATION FUNCTION IN NON-TRANSFORMING MUTANTS OF POLYOMA VIRUS. (E.) Benjamin, T. L. (Publ. Hlth. Res. Inst. New York, N.Y.) and M. M. Burger. *Proc Nat Acad Sci* 67(2):929-934, 1970.

The ability of polyoma virus infection to expose an agglutinin-binding site on the membrane of cells was investigated. Normal mouse cells cultured with or without germ agglutinin were infected with polyoma virus (5-10 plaque-forming units/cell), and the agglutination was observed. Although oncogenic viruses expose the agglutination site on the cell membranes, non-transforming polyoma virus mutants do not (infection of normal mouse cells with these mutants produced 0% agglutination). In transforming wild-type polyoma virus infection, however, did expose the agglutination-site, producing 10-15% agglutination. Inhibitors of DNA synthesis, such as thymidine and 5-fluorodeoxyuride-5'-P, blocked the exposure of the agglutinin-binding site by wild type polyoma virus, but this blockage was reversed when conditions allowing DNA synthesis were restored. The findings suggest that the agglutinable state of the cell membrane is important in the loss of regulation of cell growth associated with carcinogenesis.

1 HOST RANGE MUTANTS OF POLYOMA VIRUS. (E.) Benjamin, T. L. (Publ. Hlth. Res. Inst., New York, N.Y.). *Proc Nat Acad Sci* 67(1):394-399, 1970.

The 3T3 line of Swiss mouse embryo fibroblast was used as the normal line from which a line of polyoma-transformed virus-free cells was isolated which was fully susceptible to lytic infection by polyoma virus. This line was used to select virus mutants which had lost most or all of their ability to grow like the untransformed parental line while retaining the ability to grow in the transformed derivative; mutagens used were hydroxylamine (incubation of cells with 0.4M soln at pH 7.0 at 45° for 90 min) and N-methyl-N'-nitro-N-nitrosoguanidine (314 µg/ml for 33 hr starting at the 17th hr of infection). The virus mutants with the desired properties were isolated (NG-18, NG-23, HA-33 and NG59). These virus mutants were also defective in their ability to transform cells of rat or hamster origin. The cell extracts from the mutants had the same host

range as the whole virus, indicating that the mutants were blocked at some intracellular step which is necessary both for transformation in rat or hamster cells, and for the completion of virus development in mouse cells.

0682 ENHANCED ONCOGENESIS ASSOCIATED WITH LYMPHOID CELL LYSIS FROM VIRUS INFECTION AND ANTITHYMOCYTE SERA TREATMENTS. (E.) Minton, J. P. (Dept. Surg., Ohio St. U., Columbus), M. C. Dodd, M. M. Al-falluji, and M. Allietta. *Curr Topics Surg Res* 2:239-246, 1970.

The effects of antithymocyte serum on oncogenesis induced in mouse spleens by polyoma virus was investigated. Newborn mice (DBA/2J) were given injections of 2×10^5 TCID₅₀/0.5 ml polyoma virus, with or without associated i.p. injections of antithymocyte serum (ATS) (0.1 ml). Mice from all experimental groups were killed and their spleens were prepared for light and electron microscopic examination. Of 81 mice receiving ATS and virus, all but 14 died, and all of the 14 survivors developed tumors by 6 months postinfection. Mice which received ATS and virus early in life developed tumors sooner than mice treated later in life. None of the mice receiving ATS alone, virus alone, rabbit serum, or no treatment showed enhanced tumor development. On splenic examination, mice which had received 4 or more ATS injections had markedly enlarged spleens (spleen wt 600 mg average) compared to normal mice (180 mg), and mice receiving virus had depressed spleen wt (110 mg). After 4 injections of ATS, lymphoid follicles had lost their normal morphological pattern and presented the appearance of diffuse masses of transformed "blastoid" cells. These cells showed a marked increase in cytoplasm and in polyribosome formations. The ATS treatments may have been responsible for the blastoid transformation of splenic lymphoid cells; the loss of immune competence brought about by the ATS may have permitted the enhanced growth of tumors.

0683 DNA AND GENE THERAPY: UNCOATING OF POLYOMA PSEUDOVIRUS IN MOUSE EMBRYO CELLS. (E.) Osterman, J. V. (U. Maryland Sch. Med., Baltimore), A. Waddell and H. V. Aposhian. *Proc Nat Acad Sci* 67(1):37-40, 1970.

Mouse embryo cell cultures were infected with polyoma virus, with the result that pseudovirions and polyoma virions were produced. The polyoma pseudovirions consisted of host DNA fragments encapsidated by polyoma virus-coat protein; they were adsorbed and uncoated by the mouse embryo cells. Ninety min after infection, 75% of the virions had been adsorbed and 6% of the adsorbed virions were uncoated. Pancreatic DNase converted the uncoated pseudovirus DNA from an acid-insoluble to an acid-soluble form, indicating that the pseudovirus had been uncoated. The cellular site of pseudovirus uncoating is unknown.

- 0684 RAPID CONCENTRATION AND PURIFICATION OF POLYOMA VIRUS AND SV40 WITH POLYETHYLENE GLYCOL. (E.) Friedmann, T. (Salk Inst. Biol. Stud., San Diego, Calif.) and M. Haas. *Virology* 42(1):248-250, 1970.

Baby mouse kidney cells were infected with polyoma virus (large plaque variants) at an input multiplicity of 10 plaque-forming units/cell, and confluent BSC-1 cells were infected with SV40 at an input multiplicity of 2 plaque-forming units/cell. The infected cells were precipitated with polyethylene glycol in a single-phase precipitation; the virus pellets were further purified by band sedimentation in CsCl. Both viruses were recovered quantitatively and retained infectivity. Results showed that the oncogenic polyoma and SV40 viruses can be concentrated and purified rapidly by polyethylene glycol precipitation, and that such a recovery method may be more effective than methods previously employed.

- 0685 INHIBITION OF POLYOMA-VIRUS ONCOGENESIS IN RATS BY POLYRIBOINOSINIC-RIBOCYTIDYLIC ACID. (E.) Vandeputte, M. (Rega Inst., U. Leuven, Belgium), S. K. Datta, A. Billiau and P. De Somer. *Europ J Cancer* 6(4):323-327, 1970.

Rats were inoculated with polyoma virus in association with an i.p. injection of polyriboinosinic-polyribocytidylic acid to investigate the inhibition of tumorigenesis by this compound. Polyriboinosinic-polyribocytidylic acid (100-300 µg dose, total of 0.96-1.36 mg) significantly reduced the incidence of tumors in virus-infected rats (62-72%) compared to controls (91%); this protective effect was observed not only when polyriboinosinic-polyribocytidylic acid was given before and immediately after the virus inoculation also when polyriboinosinic-polyribocytidylic acid treatment was started 7-21 days after inoculation. This finding indicates that mechanisms other than an interferon antiviral mechanism are responsible for the protective effect. Polyriboinosinic-polyribocytidylic acid did not seem to exert a direct antitumor effect on transplantable polyoma tumors in the rat, indicating that an increase of the immunologic response in the host was responsible for the compound's inhibitory action on polyoma oncogenesis.

- 0686 COMPARATIVE STUDY OF CHROMOSOME ABERRATION IN CELL CULTURES INDUCED BY TUMORIGENIC NON-TUMORIGENIC ADENOVIRUSES. (E.) Zapsepina, (Mechnikov Res. Inst. Virol. Epidem., Odessa, A. G. Stopchanskaya, G. I. Oleinik, N. I. Lys and E. I. Gaidar. *Acta Virol* 14(5):411, 1970.

- 691 ENHANCEMENT OF TUMOR INDUCTION IN MICE BY LONG TERM IMMUNOSUPPRESSION. (E.) Mandel, A. (Case Western Reserve U. Sch. Med., Cleveland, Ohio) and J. J. De Cosse. *Surg Forum* 21:129-131, 1970.

The effect of antithymocyte serum upon the induction of plasmacytomas by Bayol F, a petroleum by-product, was investigated. Young adult mice were given 3 i.p. injections of 0.5 ml of Bayol F at monthly intervals in association with the chronic or acute administration of antithymocyte serum. Mice chronically treated with antithymocyte serum developed plasmacytomas as early as 2 months after Bayol F treatment, and 70% of mice had tumors at 6 months. This effect was not seen in control mice, in mice acutely treated with antithymocyte serum, or in mice immunosuppressed with azathioprine, cyclophosphamide or 250 r of X-ray. Possibly the increased rate of tumorigenesis observed with antithymocyte serum was caused by the alteration of a tumor surveillance mechanism in the host which, in concert with the immunosuppressive effect proper, resulted in an increased rate of oncogenesis.

- 692 DEVELOPMENT OF SEVERE CERVICAL DYSPLASIA UNDER TREATMENT WITH AZATHIOPRINE (IMURAN). (E.) Schramm, G. (Prof. Reis Private Hosp., Munich, Germany). *Acta Cytol* 14(8):507-509, 1970.

The association of the development of severe cervical dysplasia with azathioprine (Imuran) treatment is presented in the case history of a woman who developed dysplasia while under Imuran treatment for autoimmune hepatitis. When the patient (after being on and off Imuran over a 10 month period) underwent a therapeutic abortion at 2 months into pregnancy, only necrotic tissue was found instead of the fetus, and an histological examination 6 months later revealed an advanced borderline lesion or carcinoma *in situ*. A cold knife conization and curettage was performed and the patient recovered without difficulty. Azathioprine treatment was maintained despite the histological findings to prevent progression of the hepatitis, but regular cervical and vaginal smears were scheduled to maintain check for possible recurring cancer.

- 693 CERVICAL DYSPLASIA AND CANCER DEVELOPING IN WOMEN ON IMMUNOSUPPRESSION THERAPY FOR RENAL TRANSPLANTATION. (E.) Kay, S. (Med. Coll. Virginia, Richmond), W. J. Frable and D. M. Hume. *Cancer* 26(5):1048-1052, 1970.

The possibility of an association between cervical dysplastic changes and immunosuppressive therapy for renal transplantation was explored in 28 transplant patients. Patients were aged 11-46 yr, and all had received a minimum of 600 rads to the transplanted kidney, and were maintained on azathioprine and prednisone. Three patients showed cellular abnormalities on Papanicolaou smears. One patient showed mild dysplasia in only 1 smear, but

the other 2 have shown persistent atypia and 1 of the 2 developed *in situ* epithelioma proven by cervical conization. Definite proof that the cervical changes are due to immunosuppressive therapy is lacking; nevertheless, routine screening for cervical dysplasia should be carried out in connection with all transplant operations.

- 0694 LYMPHOSARCOMA IN SIBLINGS, ASSOCIATED WITH CYTOGENIC ABNORMALITIES, IMMUNE DEFICIENCY, AND ABNORMAL ERYTHROPOIESIS. (E.) Freeman, A. I. (Roswell Park Mem. Inst., Buffalo, N. Y.), L. F. Sinks and M. M. Cohen. *J Pediat* 77(6):996-1003, 1970.

A 12-yr-old boy whose sister had died with generalized lymphosarcoma was found to have a lymphosarcoma in the oropharynx. Chromosome studies of a 72-hr peripheral leucocyte microculture showed a group A chromosome which had been replaced by 2 large fragments. Immunological studies showed markedly subnormal circulating levels of IgG, IgA and IgM, and a defect in cellular immunity; hematological findings included ineffective erythropoiesis with low-grade anemia, megaloblastic changes, and multinucleated erythroblasts. The propositus' sister had been similar in physical appearance to the boy, and had had a defect in the thymic-dependent system. Although the symptom constellation exhibited by the propositus and his sister resembles that of Bloom's syndrome, it appears that the reported case represents a new disease entity.

- 0695 SPONTANEOUS DEVELOPMENT OF MAMMARY ADENOCARCINOMA FOLLOWING PROLONGED IMMUNOSUPPRESSION IN THE DOG. (E.) Joseph, W. L. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), F. Melewicz and D. L. Morton. *Cancer Res* 30(10):2606-2608, 1970.

A female mongrel dog being tested for cutaneous hypersensitivity to 2,4-dinitrochlorobenzene underwent immunosuppressive therapy with azathioprine (4 mg/kg/day) for 41 days; the dog developed adenocarcinomas in 2 breasts which were noticed 31 days after initiation of treatment. Simple mastectomy was performed on both breasts and 3½ months later when the dog died, autopsy revealed breast tumors with metastasis to the lung. The case provides further evidence of the association of immunological incompetence and neoplasms.

- 0696 THE EFFECT OF PREDNISOLONE ON RNA- AND DNA-SYNTHESIS IN PHYTOHEMAGGLUTININ-STIMULATED LYMPHOCYTES. (Ger.) Drings, P. (Med. U. Clin. Heidelberg, Germany), E. Fölsch and J. Drews. *Z Ges Exp Med* 153(1):35-50, 1970.

The possibility that prednisolone exercises a preferential inhibitory action upon a ribosomal RNA precursor was investigated. Lymphocyte cultures were taken from healthy patients (without blood dyscrasias) and incubated in a chromosome medium

containing phytohemagglutinin (PHA). Prednisolone hemisuccinate introduced into the culture at a concentration of 30 µg/ml caused a significant inhibition of ³H-thymidine (DNA precursor) incorporation, and the degree of this inhibition was dependent upon the time of introduction of the steroid into the culture medium and the duration of the reaction. Also, directly following PHA stimulation, ³H-uridine incorporation was inhibited. The decrease of RNA synthesis caused by prednisolone was attributed to a decrease in the formation of RNA ribosomal precursor. The fact that the formation of ribosomal RNA in PHA-stimulated lymphocytes was inhibited by prednisolone does not indicate that this mechanism is the only one underlying the catabolic or anabolic effect of prednisolone on lymphocytes.

- 0697 NUCLEAR AND CYTOPLASMIC PROTEIN ACCUMULATION IN PHA-STIMULATED HUMAN LYMPHOCYTES DURING BLASTOGENESIS. (E.) Soren, L. (Karolinska Inst., Stockholm, Sweden). *Exp Cell Res* 59(2):244-248, 1970.

Human lymphocyte cultures were subjected to phytohemagglutinin stimulation, and the increase in nuclear and cytoplasmic mass during blastogenesis was measured by microinterferometry for the purpose of determining nuclear and cytoplasmic protein accumulation in phytohemagglutinin stimulated cells. Both nuclear and cytoplasmic mass increased many-fold during blastogenesis, the increase of cytoplasmic mass being relatively greater than that of nuclear mass; the mean ratio of nuclear mass to cytoplasmic mass for lymphocyte populations before phytohemagglutinin stimulation and 24, 48 and 96 hr after stimulation decreased from 2.9 to 1.7. A considerable part of nuclear mass accumulation occurred before the initiation of DNA synthesis. This is different to nuclear mass increase in tissue cultured cells in logarithmic phase of growth, in which nuclear mass increases parallel to DNA synthesis. However, the mass accumulation after initiation of DNA synthesis is probably related to the increased DNA content of the transformed cell and is similar to accumulation occurring in tissue cultured cells in the logarithmic phase of growth.

- 0698 LYMPHOCYTE TRANSFORMATION IN MEGALOBlastic ANAEMIA: MORPHOLOGY AND DNA SYNTHESIS. (E.) Das, K. C. (Roy. Postgrad Med. Sch., London, England) and A. V. Hoffbrand. *Brit J Haemat* 19(4):459-468, 1970.

The morphology and DNA synthesis of phytohemagglutinin (PHA) transformed lymphocytes from 7 patients with megaloblastic anemia due to deficiency of vitamin B₁₂ or folate were compared to similarly transformed lymphocytes from normal subjects. The mean transformation (78%) was similar for both groups, but the transformed lymphocytes from the patients with megaloblastic anemia were larger with

an increased cytoplasmic-nuclear ratio and a more finely reticulated chromatin pattern. Total DNA content (µg/culture) of the transformed cells was the same in both groups (79.5-84.7), but ³H-thymidine incorporation (cpm/ µg DNA) was significantly higher in the anemic group (5067) than in the controls (2050). In normal transformed lymphocytes deoxyuridine (10⁻¹ µM) reduced ³H-thymidine incorporation to less than 10% of the control value in megaloblastic anemia-transformed lymphocytes; deoxyuridine only reduced incorporation to 65-10% of control values (with 1 culture reduced to 20% of the control). Vitamin B₁₂ (500 ng/culture) partially restored the blocking effect (55-60% inhibition), and folic acid (22 ng/culture) and folic acid (20 ng/culture) completely restored the blocking effect of deoxyuridine (11-19% inhibition).

- 0699 EFFECTS OF ADRIAMYCIN ON HUMAN LYMPHOCYTES STIMULATED WITH PHA *IN VITRO*. (E.)

Massimo, L. (G. Gasslini Dept. Pediat., U. Genoa, Italy), F. Dagna-Bricarelli and A. Fossati-Guglielmoni. *Rev Europ Etud Clin Biol* 15(7):779, 1970.

The effect of adriamycin, an antitumor antibiotic on normal human lymphocytes which were stimulated with phytohemagglutinin *in vitro* was investigated. Lymphocytes from normal donors were cultured with phytohemagglutinin; adriamycin was added in amounts of 0.05-5 µg/ml, and blastogenesis and cytogenetic changes were assayed at different concentrations of adriamycin. Adriamycin inhibited transformation of lymphocytes to blast cells at all concentrations with inhibition approaching 100% as adriamycin concentration approached 3.0 µg/ml. Giant blast cells (50-70µ), basophilic cytoplasm and pyknotic cells began to appear at adriamycin doses of 0.05-0.1 µg/ml. Chromosome aberrations such as breaks, fragments, chromatid exchanges, dicentric rings, aneuploidy and polyploidy were observed even at the lowest concentrations of adriamycin. The mutagenic effect of adriamycin may account for the inhibition of blastogenesis, cellular gigantism and hyperploidy; this effect is the most evident action of the agent on phytohemagglutinin-stimulated lymphocytes.

- 0700 EFFECT OF HAEMATOPOIETIC HUMORAL FACTORS ON PHA-TRANSFORMED LYMPHOCYTES: INHIBITION OF DNA SYNTHESIS IN PHA-STIMULATED LYMPHOCYTE CULTURE AND THE ROLE OF FACTORS CONTROLLING ERYTHROPOIESIS. (E.) Doklen, A. (Frederic Joliot-Curie Natl. Res. Radiobiol. Radiohyg., Budapest, Hungary), V. Varteres and L. Varga. *Haematologia* 4(2):201, 1970.

The effect of hematopoietic humoral factors on lymphocyte cultures stimulated with phytohemagglutinin (PHA) was studied. Lymphocyte cultures were prepared from the blood of normal rabbits and were cultured with PHA for 24-96 hr, and hematopoiesis was assayed by measuring Fe⁵⁹ incorporation by lymphocytes. Cells displaying the morphological characteristics of polychromatic and orthochromatic

ormoblasts were found in the PHA-transformed 72 hr and 96 hr cultures. These cultures also exhibited reticulocytes in different maturation phases. In all PHA-stimulated cultures, heme-synthesis proceeded as measured by Fe^{59} incorporation into hemoglobin, whereas in control cultures, heme-synthesis was not as appreciable. The addition to the cultures of anemic rabbit serum considerably (56-227%) increased Fe^{59} -incorporation into hemoglobin, whereas hypertransfused serum reduced Fe^{59} -incorporation in all cases. Both these humoral factors are known to stimulate or inhibit erythropoiesis, and both had their respective effects when added to cultures 24 hr after the addition of PHA. When added to cultures simultaneously with PHA, however, these humoral factors failed to interfere with heme-synthesis. Peripheral mononuclear cells cultured without PHA apparently did not synthesize heme, and were insensitive to the erythropoietic effect. Mononuclear cells pretreated with PHA, however, began to synthesize heme and became responsive to erythropoietic factors. It was not clear whether all mononuclear cells were responsive in these ways to PHA stimulation.

0701 STUDIES OF FOLATE UPTAKE BY PHYTOHEMAGGLUTININ-STIMULATED LYMPHOCYTES. (E.)
as, K. C. (Roy. Postgrad. Med. Sch., London, England) and A. V. Hoffbrand. *Brit J Haemat* 19(2): 203-221, 1970.

The incorporation of folates by peripheral human blood lymphocytes was studied in cultures stimulated with phytohemagglutinin. The rate of incorporation of tritiated folic acid and of ^{14}C -labeled 5-methyltetrahydrofolic acid by lymphocytes measured in stimulated and unstimulated cultures correlated with rates of DNA and RNA synthesis. In phytohemagglutinin-stimulated cultures, total folate incorporation measured by autoradiography and by liquid scintillation counting was far greater than the incorporation of folates in unstimulated cultures; at 30 hr of incubation, 3×10^6 stimulated lymphocytes incorporated radioactive folates at a rate of 575 cpm, while unstimulated lymphocytes incorporated folates at a rate of 150 cpm at 30 hr. Apparently, growing and dividing cells take up folates more readily than mature non-dividing cells. Temperature affected folate uptake; incorporation at 4°C was 80% less than uptake at 37°C . Folate uptake exhibited saturation kinetics and was inhibited by methotrexate in concentrations higher than 10^{-6}M . Peak rates of folate uptake occurred at 44-48 hr of culture in stimulated cells and preceded peak DNA synthesis by 24 hr, and followed peak RNA synthesis by the same amount of time. However, folate uptake did not appear to be directly related to either RNA or DNA synthesis, for actinomycin D inhibited nucleic acid synthesis without affecting folate uptake. An active transport mechanism may be involved in cellular folate uptake, but the 2 folates tested probably do not share the same uptake pathway, since folic acid did not inhibit the uptake of 5-methyltetrahydrofolic acid by stimulated cells. In addition, the uptake of the

latter compound was significantly impaired in lymphocytes from patients with untreated pernicious anemia, while folic acid uptake in these cells was normal.

0702 THE EFFECT OF CYCLIC AMP AND RELATED COMPOUNDS ON HUMAN LYMPHOCYTE TRANSFORMATION (HLT) STIMULATED BY PHYTOHEMAGGLUTININ (PHA). (E.)
Rigby, P. G. (U. Nebraska Coll. Med., Omaha) and W. L. Ryan. *Rev Europ Etud Clin Biol* 15(7):774-777, 1970.

The effect on human lymphocyte transformation *in vitro* of adenosine-3',5'-monophosphate (cyclic AMP) and related compounds was investigated in lymphocyte cultures stimulated with phytohemagglutinin and in unstimulated cultures. It was found that cyclic AMP and the related compounds 3'-AMP, 2',3'-AMP, 5'-AMP, and 2',3'-guanosine monophosphate and 3',5'-guanosine monophosphate reduced the number of normal lymphocytes in phytohemagglutinin-stimulated tissue culture, the reduction being most evident after 4 days of cultivation. At 3 mg cyclic AMP/ 3 cm^3 of culture, lymphocyte counts were reduced to 49% of control; the same dose of 5'-AMP reduced lymphocyte counts to 36% of normal. Without phytohemagglutinin, treatment with cyclic AMP and related compounds did not markedly reduce the numbers of cells, but the cell counts were invariably reduced in unstimulated cultures. In unstimulated cultures, 3 mg cyclic AMP/ 3 cm^3 of culture reduced lymphocyte counts to only 77% of normal. The role of cyclic AMP and related compounds on lymphocyte proliferation *in vivo* is not clear, although at physiological levels DNA synthesis and mitotic activity are promoted in cultures.

0703 DNA POLYMERASE AND DNA REPLICATION DURING LYMPHOCYTE TRANSFORMATION. (E.) Loeb, L. A. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.), J. L. Ewald and S. S. Agarwal. *Cancer Res* 30(10): 2514-2520, 1970.

Lymphocytes from the blood of healthy human volunteers were treated with phytohemagglutinin and ^3H -methylthymidine (50 μC), and DNA polymerase and replication activity was observed. An increase of 30- to 150-fold in DNA polymerase activity paralleled in time and magnitude the ability of the cells to synthesize DNA. An increase in DNase activity also paralleled DNA synthesis and the rise in polymerase. The activities of thymidine kinase and thymidine monophosphate kinase multiplied about 2- to 10-fold. In contrast, kinases such as deoxyguanosine monophosphate kinase and guanosine monophosphate kinase, which were present in greater activity, were not increased by phytohemagglutinin. The induction of these enzyme activities by phytohemagglutinin appears to require RNA synthesis. Actinomycin D in concentrations greater than 0.015 $\mu\text{g}/\text{ml}$ abolished the phytohemagglutinin-mediated increases in RNA and DNA synthesis, enzyme activities, and lymphocyte transformation. Smaller amounts of actinomycin (0.005 $\mu\text{g}/\text{ml}$) prevented the induction of DNA

polymerase, thymidine kinase, and thymidine monophosphate kinase, as well as the increase in RNA and DNA synthesis, but did not hinder lymphocyte transformation. Evidently, the stimulation of DNA synthesis depends on the induction of DNA polymerase. In contrast, the morphological changes associated with lymphocyte transformation do not appear to require DNA replication or the increases in enzyme activity associated with this replication.

- 0704 IMMUNOLOGICAL FACTORS IN HUMAN SARCOMAS AND MELANOMAS: A RATIONAL BASIS FOR IMMUNOTHERAPY. (E.) Morton, D. L. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), F. R. Eilber, W. L. Joseph, W. C. Wood, E. Trahan and A. S. Ketcham. *Ann Surg* 172(4):740-749, 1970.

The relationship between the clinical progress of human melanomas and sarcomas and the immune response of the patient to his tumor was investigated. Anti-melanoma antibodies were found in 67% of patients with malignant melanoma, and in 22% of normal subjects. Fewer patients with metastatic melanomas had antibodies (26%) than patients with localized melanoma (89%). All patients undergoing spontaneous regression of melanoma had unusually high anti-melanoma antibody titers. Patients with sarcoma conditions showed similar immune profiles, antibody titers increasing following surgical resection of tumors, and declining in patients with recurrent sarcomas or with pulmonary metastases. In experiments with guinea pigs, the correlation between antibody titers and malignancy was explored further. Living cells from methylcholanthrene-induced liposarcomas were injected into animals which were then immunized with mixtures of BCG and irradiated tumor cells or BCG and living tumor cells. Both treatments significantly inhibited growth of the i.m. injected liposarcoma, but the living cells were more effective inhibitors than irradiated cells. Thirty days after liposarcoma injection, 27 of 28 control guinea pigs bore tumors, while 12 of 20 animals treated with irradiated cells and BCG, and none of 20 treated with living tumor cells and BCG, bore tumors. In studies with human patients, 12 patients with malignant melanoma, skeletal and soft tissue sarcoma were given immunotherapy. All patients treated with tumor cells and BCG exhibited rising titers of anti-sarcoma antibodies, and a temporary decrease in the growth rate of pulmonary metastases was observed in 2 patients following immunotherapy. Immunotherapy using BCG and tumor cells apparently may be indicated as an adjunct treatment with surgery for melanoma and sarcoma conditions.

- 0705 *SACCHAROMYCES CEREVISIAE*, AN IMMUNOLOGICAL FACTOR IN THE INHIBITION OF SARTORELLI'S TG 180 ASCITES SARCOMA TRANSPLANTATION IN MICE. (Fr.) Vermeil, C. (Fac. Med. Nantes, France) and O. Morin. *C R Acad Sci* 271(3):378-380, 1970.

Complete protection against the peritoneal graft a TG-180 ascitic sarcoma in mice was obtained by inoculation of cycloheximide-modified *Saccharomyces cerevisiae* (Charron's strain). The yeast (200 mg) were first treated with cycloheximide (0.01% physiological solution with 2% glucose) for 1 hr at 25°C and then inoculated into a sarcoma-bearing mouse, i.p. The animal was sacrificed 1 hr later and the ascites, containing sarcoma and yeast cells, was recovered, twice frozen and thawed, and then centrifuged to partially separate yeast from the tumor cells. These yeast cells were then inoculated into 3 mice i.p. for 4 times at weekly intervals, and the treated mice along with controls were inoculated with 1000-2000 sarcoma cells each, i.p., 1 wk following the last yeast cell treatment. No tumors developed in the pretreated mice while usual sarcomatous evolution occurred in the control animals.

- 0706 PROPERTIES OF SARCOMAS INDUCED BY FERRIDEXTRAN SPOFA IN THE INBRED RAT STRAIN AVN: I. TRANSPLANTABILITY OF FEDEX-AVN TUMOURS *VIVO* AND KARYOLOGICAL AND MORPHOLOGICAL PROPERTIES OF THE CELL LINE AFTER EXPLANTATION *IN VITRO*. (E) Kren, V. (Fac. Gen. Med. Charles U., Prague, Czechoslovakia), D. Krenova and O. Stark. *Neoplasia* 17(4):329-337, 1970.

The morphology, karyotype, and transplantability of sarcomas induced in strain AVN rats by i.m. administration of Ferridextran Spofa were investigated. The tumors were spinocellular sarcomas with some expression of fibroid production; after 7 months *vivo* passaging, the tumor presented the appearance of a pleomorphic malignant mesenchymal neoplasm. Tumors were transplantable in the original rat strain, and the rate of implanted tumor growth was related to the elapsed time from induction of transplanted tumors. Tumors transplanted earliest after induction grew most slowly. Rats of the allogeneic strains BP, LEW, and WP rejected tumor transplants and produced anti-tumor hemagglutinins. Rat strains having the H-1^a positive allele sustained tumor transplants in only negligible numbers (4 of 14 H-1^a positive rats). When doses of 5×10^5 or 1×10^5 tumor cells were administered to semi-syngeneic hybrid rats the time of survival of the rats was longer than the time of survival of syngeneic rats. Karyotypically, the tumor was high polyploid with most mitoses having chromosome complements of 55-75 chromosomes. The low growth ability of the tumor on H-1^a positive and semi-syngeneic rats may be accounted for by allogeneic inhibition.

- 0707 ANTIGENIC CHANGES IN GASTRIC CANCER. Ortiz De Landazuri, M. (Fac. Med. U. Navarra, Spain) and A. Chordi. *Rev Clin Espagn* 118(5):441-446, 1970.

Immunoelectrophoretic data on gastric cancer antigens were compared to those obtained with normal gastric tissues (duodenal ulcer patients) and with antigens from embryonic tissues (less than 5 months).

of gestation). Normal gastric tissue extracts had 20 immunologically different antigens of which 7 were in common with serum, 2 were in common with other organs (thyroid) and 11 were organ-specific. The gastric cancer tissue extracts had 20 antigens of which 10 were in common with serum, 2 were in common with other organs (thyroid) and 8 were gastric cancer-specific. Complete disappearance of normal organ-specific G133, G113 and G90 antigens and considerable decrease of organ-specific G53, G46a, G46b and G46c occurred in the cancer tissue, while the number of serum antigens was increased (from 7 to 10). Common for both normal and cancer tissues were G12, G28, G85 and G100 antigens. The presence of 4 antigens, specific for cancer tissue, was ascertained in the total cancer tissue homogenate and their distribution in subcellular fractions was determined. These were designated as N46a, N46b (predominant in the soluble cytoplasmic, mitochondrial and microsomal fractions) and N28 and N80 (predominant in the total cancer tissue homogenate). A distinct precipitation band (electrophoretic mobility=46) was noticed in the total fetal tissue homogenate, which was in common with the 46b cancer tissue antigen and was designated as the carcinoembryonic 46b antigen.

0708 DIFFERENT LOCATIONS OF CARBOHYDRATE-CONTAINING SITES IN THE SURFACE MEMBRANE OF NORMAL AND TRANSFORMED MAMMALIAN CELLS. (E.) Sela, B. A. (Weizmann Inst. Sci., Rehovoth, Israel), H. Lis, N. Sharon and L. Sachs. *J Membrane Biol* 3(3): 267-279, 1970.

The action of soybean agglutinin (SBA) and its receptor site on the surface membrane were studied in normal and transformed (by polyoma virus, SV40, or adenovirus) human mouse, rat, and hamster cell lines. The transformed human, mouse, and rat cells were agglutinated by SBA (50-100 µg/ml), but the transformed hamster cells and all of the normal cell lines were not agglutinated. Normal cells became agglutinated by SBA after trypsin or pronase treatment (10 µg/ml for 5 min), but transformed hamster cells could be agglutinated only after prolonged pronase treatment (30-90 min). N-Acetyl-D-galactosamine (0.15 µmoles/ml) inhibited the agglutination by 50%, indicating that N-acetyl-D-galactosamine-like saccharides are part of the receptor sites for SBA on the surface membrane and exist in a cryptic form in normal human, mouse, and rat cells and become exposed in transformed cells (although they become less accessible in transformed hamster cells). Wheat germ agglutinin and Concanavalin A agglutinin interacted with different receptor sites (N-acetyl-D-glucosamine-like and α-D-glucopyranoside-like sites, resp.), and the sites for the different agglutinins became exposed in normal hamster cells after trypsin (1 µg/ml) treatment for 1, 3 and 5 min for wheat germ, Concanavalin A and SBA, resp.

0709 IMMUNOLOGICAL STUDIES ON YOSHIDA SARCOMA CELLS: II. CELLULAR LOCALIZATION OF HETEROLOGOUS ANTI-YOSHIDA SARCOMA CELL ANTIBODIES AND IMMUNOHEMOLYTIC ANEMIA INDUCED BY THEIR INJECTIONS

IN THE RAT. (E.) Sugiyama, H. (Fac. Med. U. Tokyo, Japan) and T. Kuroyanagi. *Japan J Exp Med* 40(3): 191-199, 1970.

The effect of absorption of heterologous anti-Yoshida sarcoma (YS) serum with YS antigens on the penetration of anti-YS cell serum into viable YS cells was investigated in immunofluorescence tests. Anti-YS serum was prepared in rabbits; the YS cell antigens fractionated for study were the nuclear fraction and the insoluble sediments of supernatants derived from centrifugation of YS cell homogenates. When viable YS cells were incubated with heterologous anti-YS serum without complement, anti-YS serum did not penetrate the viable cells, while penetration did occur in the presence of complement. The absorption of serum with supernatants of YS cells had no effect on its penetration into YS cells in the presence of complement. However, when anti-YS serum was absorbed with the insoluble sediment of YS cells or normal rat red cell membranes, penetration of serum into YS cells did not take place. These results were thought to indicate that antigens responsible for the antibody which plays the major role in anti-YS serum penetration were present in the insoluble sediment of YS cells, and that these antigens had common antigenicity with normal rat red cell membranes. The hypothesis was tested by injecting Donryu rats with 0.5 ml of anti-YS cell serum or with 0.5 ml of serum which had been absorbed with the insoluble sediment of YS cell homogenates. The former treatment, but not the latter, induced immunohemolytic anemia in the rats. Ferrokinetic studies using ⁵⁹Fe showed a prolongation of the generation cycle of nucleated erythroid cells in rats injected with anti-YS cell serum. The anemia and the prolongation of the generation cycle may have been due to incomplete antibodies present in the anti-YS cell serum.

0710 IMMUNOLOGIC AND IMMUNOTHERAPEUTIC STUDIES WITH HUMAN SARCOMAS. (E.) Eilber, F. R. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and D. L. Morton. *Surg Forum* 21:127-129, 1970.

Antisarcoma antibody titers were assayed in 35 patients with skeletal and soft tissue sarcomas to determine whether there was a correlation between antisarcoma antibody titer, delayed cutaneous hypersensitivity to the sarcoma antigens, and the clinical course of the malignant disease. A good correlation was found between antisarcoma antibody titer and the clinical course. High antibody titers (1/32 or greater) were found in patients surviving longer than 3 yr following primary treatment for sarcoma. Elevated titers were found in patients remaining tumor-free following surgery, while patients developing recurrence of tumors exhibited declining antibody titers. Immunization with 75 x 10⁶ irradiated (15,000 r) autologous tumor cells reversed the decline of circulating antibodies. Antibody activity was found to be associated with immunoglobulins of types IgG and IgM. In 7 patients having elevated antibody titers following immunization delayed cutaneous hypersensitivity to 1 x 10⁶ autologous irradiated tumor cells and ether soluble sarcoma antigen was noted.

- 0711 A COMPLEMENT BINDING REACTION TO DEMONSTRATE COMMON ANTIGEN COMPONENTS IN THE LEUKEMIA VIRUS OF VARIOUS MAMMALS. (Ger.) Schäfer, W. (Max Planck Inst. Virus Res., Tübingen, Germany), J. Lange, L. Pister, E. Seifert, F. De Noronha and F. W. Schmidt. *Z Naturforsch* 256(9):1029-1036, 1970.

The prevalence of leukemia viruses in various animal species suggests that malignancy in man could also be attributed to this virus. The antigen formation of this RNA containing complex virus is reminiscent of the influenza viruses. Serological comparison of avian leukemia virus (ALV), murine leukemia virus (MLV), feline leukemia virus (FLV) and hamster leukemia virus revealed the presence of an interspecies specific (gs-interspecies) antigen except in case of ALV. Rabbit immunization with purified MLV-gs-antigen allowed isolation of an antiserum (R-gs-serum) which precipitated specifically the MLV and FLV gs-antigens. The complement binding tests with R-gs-rabbit serum proved to be 5 times more sensitive against FLV; preliminary investigations with cattle and human material using this serum gave results which seemed to be positive.

- 0712 PRELIMINARY COMMUNICATION ON THE EVIDENCE OF ANTIBODIES AGAINST VARIOUS BLAST TYPES IN PERSONS EXPOSED TO ACUTE PEDIATRIC LEUKEMIAS. (Ger.) Ziantl, F. (U. Child. Clin., Jussuf Ibrahim, Jena, Germany), G. Aurich and W. Plenert. *Folia Haemat* 94(1):31-40, 1970.

The sera of 39 contact persons, consisting of physicians and other staff personnel who had been in contact with leukemic children, as well as the sera of the children's parents, were tested for antibodies against acute infant leukemia by immunofluorescent techniques. The target cells were taken from 3 different children with: monocytoid blasts, "paramyelo blasts", and "parablasts", resp. A positive membrane fluorescence with the 3 cell types was found among the tested contacts in varying amounts. The most frequent positive reactions were in response to the application of "parablasts". The control tests performed in subjects who had never been exposed to leukemia patients were all negative.

- 0713 BLAST CELL LEUKAEMIA ASSOCIATED WITH IgA PARAPROTEINAEMIA AND BENCE JONES PROTEIN. (E.) Thijs, L. G. (Dept. Intern. Med., Free U., Amsterdam, Netherlands), W. Hijmans, W. Leene, O. G. Muntinghe, R. N. I. Pietersz and J. E. Ploem. *Brit J Haemat* 19(4):485-492, 1970.

Blast cell leukemia associated with IgA paraproteinemia and Bence Jones protein was illustrated in the case of a 47 yr-old female patient. The patient was diagnosed as having myeloblastic leukemia, with IgA kappa paraproteinemia and with Bence Jones kappa proteins in her serum and urine. Although it appeared that two neoplastic conditions involving both the myelocytic and the plasma cellular series were in effect, electron microscopy and immunofluorescence tests revealed that the blast cells belonged to the plasma cell series. Accordingly,

the diagnosis was changed to myeloma with leukemia and this diagnosis was borne out at autopsy which revealed a typical "myeloma kidney" condition. cases of blast cell leukemia care should be taken to search for paraproteins.

- 0714 HL-A ANTIGENS ON LEUKAEMIC CELLS. (E.) Pegrum, G. D. (Charing Cross Hosp. Med. Sch., London, England), I. C. Balfour, C. A. and V. L. Middleton. *Brit J Haemat* 19(4):493-498, 1970.

The frequencies of HL-A antigens in leukemic cell lines was investigated. Antigen assays were carried out in blood from 26 patients with leukemic conditions with alloantisera which recognized 13 HL-A antigen specificities. Increased incidences of HL-A 1, HL-A 3, HL-A 7, HL-A 8 and Lc19 antigens were found, the most notable being the increase in HL-A 3 antigen frequency from 25% in normal subjects to 57% in the leukemia patients. A slight decrease in the frequency of HL-A 2 antigen was found, the frequency in normal controls being 49% and the frequency in leukemic patients being 34.5%. These findings suggest that leukemic cells either react differently to the alloantisera or that additional tumor-specific antigens are present on the cells. It is also possible that a genetic predisposition to develop leukemia characterizes people with the antigenic configurations.

- 0715 SPECIFICITIES OF γ A-MYELOMA PROTEINS. Tominaga, K. (Fac. Med. Kyushu U., Fukuoka, Japan). *Acta Haemat Jap* 33(1):85-86, 1970.

The relationship between the subclass and polypeptide chain structure was examined in 5 purified myeloma proteins with identified subclasses. The lowest protein concentrations (mg/ml) for positive reaction against γ A1- and γ A2-specific antisera were 0.23 and 15 for Gb, 0.16 and 2.5 for Hr, 0.16 for Kt, 0.23 and 1.9 for Fr, and 0.15 and 0.15 for Kw subclasses. L chain dimer dissociation was observed in Hr. Reduced γ A-myeloma protein Hr transformed more slowly than its oxidized counterpart indicating a difference from others in the polypeptide chain structure. Kw showed a slight tendency toward chain dissociation in disc electrophoresis, while L chain dissociation was seen in Fr, although the protein reacted against anti- γ A2 antiserum in relatively low concentration.

- 0716 THE MECHANISM AND SIGNIFICANCE OF PERIODIC PLOIDY-ALTERATIONS IN THE MOUSE MYELOMA MSPC-1. (E.) Moriwaki, K. (Natl. Inst. Genet., Misima, Japan) and H. T. Imai. *Acta Haemat Jap* 33(1):67-78, 1970.

The cytological mechanisms and immunological significance of the periodic ploidy changes from diploid to tetraploid in several transplantable myelomas of the mouse myeloma, MSPC-1, over a 100 day period were studied with marker chromosomes and autoradiography in BALB/c mice. Pretreatment of the cells with γ -irradiation (200 r) decreased the tumor

duction period by 2 days but did not create any significant differences in the ploidy changes. Tetraploid cells were formed from diploids through the failure of cytokinesis and the fusion of binuclei in the binucleate-cell stage, while diploidization occurred through a degeneration of the tetraploid cells (with an unexplained cytological mechanism) and a minor fraction of existing diploid cells resumed active proliferation. The growth pattern in the MSPC-1 myeloma (where the active diploid population maintained a few repressed diploids) was similar to the pattern of active plasma cells capable of producing antibody and memory cells and suggests that the mechanism of antibody formation may be approached through the cytogenetics of the maturing antibody forming cells.

- 0717 LEUCOCYTE PHENOTYPES IN HODGKIN'S DISEASE. (E.) Zervas, J. D. (Roy. Natl. Orthop. Hosp., Brockley Hill, Stanmore, Middlesex, England), I. W. Delamore and M. C. G. Israels. *Lancet* 2(7674):634-635, 1970.

Hodgkin's disease patients (27) and normal controls were typed for 8 HL-A antigens (HL-A1, HL-A2, HL-A3, HL-A5, HL-A8, LA-4, LC-17, and LC-20) and their leukocyte phenotypes were determined to investigate the occurrence of HL-A specificity associated with this disease. Hodgkin's disease patients exhibited a greater frequency of HL-A5 antigen specificity with antiserum D-66-6222VI (63%) than the controls (20%). Antiserum Kieffer, which is supposed to have HL-A5 specificity, gave 86% positive reactions with leukocytes from Hodgkin's disease patients and 90% positive tests with leukocytes of healthy patients, indicating that this antiserum is not monospecific. Antisera HL-A8 and LC-17 also showed higher positive reactions with leukocytes of Hodgkin's disease patients (37% and 33%, resp.) compared to healthy patients (25% and 16%, resp.). A correlation appears to exist between Hodgkin's disease and HL-A phenotype.

- 0718 LEUCOCYTE ANTIGENS IN HODGKIN'S DISEASE. (E.) Forbes, J. F. (Dept. Surg., U. Melbourne, Australia) and P. J. Morris. *Lancet* 2(7678):849-851, 1970.

Microlymphocytotoxic techniques using between 60-120 cytotoxic antisera were employed in testing the blood of 110 patients (in groups of 35 and 75) for the frequency of an antigen designated 4c by Amiel. An antigen previously known as 4c was found in 56% and 45%, resp., of the patients in the 2 series, compared with 25% in the normal Australian population. This difference appears to be due to an increased frequency of an included antigen, W5. Family studies have shown a normal segregation of antigen W5, but have not as yet revealed any abnormal frequency of haplotypes. The association between Hodgkin's disease and the 4c antigen may indicate that the pathogenesis of Hodgkin's disease is connected with genetic or viral factors.

- 0719 CLONAL EVOLUTION IN TWO PATIENTS WITH AUTOIMMUNE DISEASE AND LYMPHORETICULAR NEOPLASIA. (E.) Adam, M. (U. West Indies, Jamaica), M. J. Thorburn, W. N. Gibbs, S. E. H. Brooks and B. Hanchard. *Brit J Cancer* 24(2):266-276, 1970.

A 36-yr-old man and a 48-yr-old woman diagnosed as having lymphosarcoma with possible autoimmune disease and autoimmune disease with possible lymphosarcoma, resp., are described. In both cases, circulating mononuclear cells showed phytohemagglutinin responsiveness (mitotic rate of 25%). Cytogenetic studies on peripheral blood cultures from the male patient showed most of the cells had hyperdiploid complements with a modal number of 48 in 50% of the cells; with bone marrow 12% of the cells had 47-50 chromosomes. Peripheral blood cultures from the woman patient had cells of two types, a normal female diploid line (40%) and a tetraploid line (60%). Large numbers of chromosome (over 90) were observed in the latter cells. The findings appear to support the hypothesis that an abnormal clone of immunocytes may be implicated in both autoimmune disease and leukemia.

- 0720 BIOSYNTHESIS OF THE CARBOHYDRATE PORTION OF IMMUNOGLOBULINS: KINETICS OF SYNTHESIS AND SECRETION OF ^3H -LEUCINE-, ^3H -GALACTOSE- AND ^3H -MANNOSE-LABELED MYELOMA PROTEIN BY TWO PLASMA-CELL TUMORS. (E.) Melchers, F. (Max Planck Inst. Molec. Genet., Berlin, Germany). *Biochem J* 119(4):765-772, 1970.

The kinetics of incorporation of ^3H -leucine, ^3H -mannose, and ^3H -galactose into the carbohydrate portion of immunoglobulins were studied in cell suspensions of 2 myeloma plasma-cell tumors, MOPC 21 which produces and secretes IgG myeloma protein and MOPC 46 which produces and secretes a κ -type light chain with attached carbohydrate. In the first 3 hr of ^3H -leucine incorporation, approximately 23% of the total acid-precipitable radioactivity was myeloma protein, and 90% of this labeled protein synthesized within the plasma cell was secreted. More than 90% of the ^3H -galactose was incorporated into galactose residues of both intracellular and secreted protein, while ^3H -mannose was incorporated significantly (90%) into glucosamine and mannose residues of intracellular protein and into glucosamine, mannose, and fucose residues of secreted protein. Addition of some of the carbohydrate residues appears to be a stepwise process with mannose and glucosamine residues added early and fucose residues added near the final stages of secretion from the plasma cell.

- 0721 RETROGENETIC EXPRESSION: THE REAPPEARANCE OF EMBRYONAL ANTIGENS IN CANCER CELLS. (E.) Stonehill, E. H. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.) and A. Bendich. *Nature* 228(5269):370-372, 1970.

The possible universal appearance of embryonic antigens in cancer tissues was investigated. Whole

mouse (Swiss) embryo extracts were used as the immunizing antigen to prepare antisera in the rabbit, and sera were screened (agar diffusion and immunoelectrophoresis) against prepared extracts of normal embryonic, neonatal, and adult antigens and against extracts of malignant cells of 72 tumors from mice of 18 different inbred strains (viral or chemical induction, irradiation, or spontaneous malignancies). Serum against 9 day mouse embryo, after absorption with normal adult organs, reacted with extracts of all 72 tumors, and with extracts of normal embryo or normal adult skin, but not with other normal adult tissues. In the mouse, such reappearance and persistence of embryonal antigens (retrogenetic expression) in malignant cells appear to be universal phenomena. It could not be determined whether retrogenetic expression is a cause or an effect of cancerigenesis.

- 0722 LYMPHOCYTIC REACTION AROUND PRIMARY AND METASTATIC MELANOMAS. (E.) Payan, H. M. (Clarksburg VA Hosp., West Virginia U., Morgantown), E. F. Gilbert and W. H. Jacobs. *Southern Med J* 63(11):1350-1352, 1970.

Lymphocytic reactions occurring in the vicinity of primary and metastatic melanomas were investigated in 15 primary tumors and in 25 metastases. Metastatic melanomas studied involved the breast, head and neck, and upper and lower extremities. Pigmentation was present in 93% of primary tumors and in 56% of metastases, while necrosis was minimal in both primary and metastatic lesions. A definite lymphocytic infiltrate was found in and around 67% of the primary tumors, and in none of the metastases. Lymphocytic reactions in primary tumors were classified as "moderate". Eighty percent of metastases were to the lungs and lymph nodes, while 60% affected the liver, central nervous system and kidneys. The presence of a lymphoid reaction in and around primary melanomas may be an indication that an immunologic response or defense mechanism exists in the tumor-body interaction.

- 0723 HEPATITIS-ASSOCIATED ANTIGEN IN UGANDAN PATIENTS WITH HEPATOCELLULAR CARCINOMA. (E.) Vogel, C. L. (Uganda Cancer Inst., Kampala), P. P. Anthony, N. Mody and L. F. Barker. *Lancet* 2(7674):621-624, 1970.

Serum was collected from 45 Ugandan patients with hepatocellular carcinoma and 122 controls in an effort to detect the presence of hepatitis-associated antigen. Eighteen of 45 (40%) patients and 4 of 122 (3%) control patients had positive complement-fixation tests for hepatitis-associated antigen. There was a tendency for hepatitis-associated antigen-positive individuals with hepatocellular carcinoma to be α -fetoprotein positive and to have underlying cirrhosis of the "posthepatic" type. Young patients tended to be hepatitis-associated antigen-positive more frequently than old patients. The presence of the hepatitis-associated antigen in liver cancer patients suggests that the etiology and pathogenesis of hepatocellular

carcinoma in Uganda may be associated with an antecedent viral-hepatitis infection, or that hepatocarcinoma patients are more susceptible to hepatitis or to persistence of the antigen in their blood.

- 0724 AUSTRALIA ANTIGEN AND PRIMARY LIVER CANCER. (E.) Moertel, C. G. (Mayo Clin., Rochester, Minn.), G. J. Gleich and E. W. Hull. *Amer J Dig Dis* 15(11):983-985, 1970.

A study designed to determine the frequency of Australia antigen in American patients with primary liver cancer is described. Of 35 patients with liver cancer, none had detectable Australia antigen. Hepatic neoplasms included in the patient series were hepatoma, mixed hepatic carcinoma, primary hepatic hemangioendothelioma, and cholangiocellular carcinoma. Of 31 control patients with nonmalignant liver conditions 3 exhibited Australia antigen (acute hepatitis, chronic active liver disease and Laennec's cirrhosis with primary carcinoma of the bile duct). Although the population studied was without Australia antigen, the possibility of an etiologic viral factor in liver carcinoma cannot be ruled out.

- 0725 COOPERATION OF IMMUNE LYMPHOID CELLS AND MACROPHAGES IN TUMOUR IMMUNITY. (E.) Evans, R. (Chester Beatty Res. Inst., Belmont, Sutton, Surrey, England) and P. Alexander. *Nature* 228(5272):620-622, 1970.

Cells of a murine lymphoma tumor were introduced into cultures of peritoneal exudate cells and macrophages prepared from mice resistant and sensitive to the murine lymphoma. Although macrophages from non-immune mice had no effect on the growth of tumor cells, growth was completely inhibited by immune-mouse macrophages. The ratio of macrophages to tumor cells was 40:1; however, cytotoxic effects were observed with macrophage-tumor cell ratios as low as 10:1. It was also found that normal macrophages, previously non-cytotoxic, become cytotoxic towards lymphoma cells following incubation with spleen cells from immune mice. The findings suggest that the success of a host in containing a tumor depends on the co-presence of immune lymphocytes and macrophages.

- 0726 UREA-EXTRACTABLE ANTIGENS IN NORMAL EPIDERMIS AND NEOPLASTIC MOUSE EPIDERMIS. Carruthers, C. (Roswell Park Mem. Inst., Buffalo, N. Y.). *Oncology* 24(5):321-334, 1970.

The antigenic relationships between the urea-extractable proteins of mouse epidermis, papillomas and squamous-cell carcinomas (induced by 0.3% methylnitrosourea) were investigated. Antisera against normal mouse epidermis, papillomas and carcinomas were prepared in rabbits, and the relationship between these antisera and the antigens of the 3 tissues were studied by immunodiffusion in agar. Normal mouse epidermis had urea-extractable antigen (UEA) in much larger amounts than did urea extracts of papillomas and squamous-cell carcinoma. Papillomas and carcinomas have several UEA in common; papilloma and

cinoma antigens were present in normal epidermis, but in small amounts. In the immunodiffusion tests, the amount of papilloma and carcinoma UEA required in order to inhibit precipitin band formation between normal skin UEA and the normal skin antigens was, resp., 16 and 14 times as great as that of the normal skin UEA, a finding which appears to suggest that there is a change in the antigenic determinants in the UEA of benign or malignant growth, or that these tissues are deficient in epidermal UEA.

0727 TUMOR IMMUNITY PRODUCED BY THE INTRADERMAL INOCULATION OF LIVING TUMOR CELLS AND LIVING *MYCOBACTERIUM BOVIS* (STRAIN BCG). (E.) Zbar, B. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), I. Bernstein, T. Tanaka and H. J. Rapp. *Science* 170(3963):1217-1218, 1970.

The specific tumor immunity produced by inoculation of guinea pigs with living tumor cells and living *Mycobacterium bovis* (strain BCG) was observed. Guinea pigs received 1.5×10^6 cells of ascites tumor line number 10 (lethal dose of 10^5 cells) and 6×10^6 bacteria cells (which produced an initial inflammatory reaction). Immunity was tested by a subsequent (31-35 days later) injection of 10^6 tumor cells. Animals immunized in this way were capable of suppressing the intradermal growth of tumor cells in a challenge inoculation ten times greater than the lethal dose. Tumor nodule size at 8 days following challenge in immunized animals was 0 and 23 mm² in control animals. Protected animals remained tumor free for 3 months after the initiation of the experiment. Immunization with BCG alone did not impair the growth of line 10 tumor cells. Animals immunized with ascites tumor line 1 did not suppress the growth of line 10 tumor cells.

0728 TRANSFER OF TUMOR IMMUNITY WITH RIBONUCLEIC ACID. (E.) Deckers, P. J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and Y. H. Pilch. *Surg Forum* 21:124-126, 1970.

The transfer of tumor-specific immunity by isologous immune RNA within a syngeneic system and the efficacy of systemic administration of immune RNA without cells in transfer of immunity was investigated. RNA was extracted from the spleens of rats which had been immunized by growth and amputation of a syngeneic benzpyrene-induced fibrosarcoma; the RNA was incubated with normal spleen cells. Untreated rats were injected i.v. with 5×10^7 to 5×10^8 RNA-incubated spleen cells for 3 days; 24 hr following the last RNA-spleen cell injection, all animals received 10^5 tumor cells. Control rats were given tumor cells alone or tumor and spleen cells preincubated with RNA from spleens of untreated rats. In the rats receiving syngeneic spleen cells incubated with immune RNA, tumors measured about 4.8 cm³, while rats receiving tumor cells and spleen cells preincubated with RNA from spleens of untreated rats developed tumors measuring 23.8 and 13.9 cm³, resp. In another experiment, rats received 10^4 tumor cells and on the same day and on alternate days for 10 days were injected with a mix-

ture of dextran sulfate and RNA prepared from lymph nodes and spleens of immunized guinea pigs. Control groups received tumor cells alone, tumor cells with dextran sulfate and RNA extracted from lymph nodes and spleens of unimmunized guinea pigs, or tumor cells and dextran sulfate. Rats receiving immune RNA from guinea pig mixed with dextran sulfate showed inhibition of tumor development (5/20 rats developed tumors) compared with rats receiving tumor cells alone (19/21 rats developed tumors), rats receiving RNA from spleens of unimmunized guinea pigs (15/21 rats developed tumors) and rats receiving tumor cells and dextran sulfate (11/11 rats developed tumors).

0729 THE SERUM PARAPROTEIN LEVEL RELATED TO THE NUMBER OF PLASMACYTOMA-5563 CELLS IN C3H MICE. (E.) Fakhri, O. (Roy. Postgrad. Med. Sch., London, England) and J. R. Hobbs. *Brit J Cancer* 24(2):395-397, 1970.

0730 THE EFFECT OF PHYTOHEMAGGLUTININ ON BURKITT'S LYMPHOMA CELL CULTURES. (Sp.) Sanchis-Bayarri Lahoz, V. (Valencia, Spain) and V. Sanchis-Bayarri Vaillant. *Medicamenta* 54(478):87-91, 1970.

0731 AN ANTIGEN IN THE URINE OF CANCER PATIENTS: DETECTION BY IMMUNO-ELECTROPHORESIS. (Fr.) Aron, M. (Fac. Med. Strasbourg, France). *C R Acad Sci* 271(5):559-562, 1970.

- 0735 CONTRIBUTIONS TO THE HISTOGENESIS OF BASAL CELL CARCINOMA. (E.) Brody, I. (Karolinska Hosp., Stockholm, Sweden). *J Ultrastruct Res* 33(1-2):60-79, 1970.

The morphology of tumor cells from superficial basal cell carcinoma in 17 patients bearing lesions on the trunk was studied under the electron microscope. In the tumor buds of superficial basal cell carcinoma, 2 basic cell types were found: cells in which the cytoplasm forms only a small zone around the nucleus (type I), and cells in which the cytoplasm constitutes a larger proportion of the cell material (type II). The major portion of tumor bud cells was composed of cells of type I. Due to differences in nuclear and cytoplasmic opacity and density 3 subtypes of cells, termed dark, intermediate and light, were seen in both types. The nuclei differed with respect to opacity and density of the nuclear matrix. The differences in opacity and density of the cytoplasm were due to differences in the number and density of the ribosomes and in the occurrence of a fairly opaque substance between the ribosomes. The mitochondria were on the whole less numerous than in normal adult epidermis, whereas the α -cytomembranes were quite numerous and the Golgi apparatus was rather well developed. The fibrils were very few compared with those in the normal adult human epidermis. The desmosomes were considerably reduced in number, whereas the nexuses were numerous and usually of some length. Along large stretches the cells lay close together. Squamous cell foci were observed in repeated studies, and they appeared to correspond to the light cells of type II. The presence of 2 main types of cells in superficial basal cell carcinoma supports the theory of Pinkus that basal cell carcinoma originates from adult but pluripotent cells.

- 0736 THE DNA CONTENT OF ALVEOLAR MACROPHAGES AND A SO-CALLED ALVEOLAR CELL CARCINOMA. (E.) Pfitzer, P. (Inst. Path., U. Dusseldorf, Germany). *Acta Cytol* 14(8):479-485, 1970.

Sputum smears from healthy patients and from a patient with large cell carcinoma of the giant cell type affecting the lung were examined microscopically to investigate the DNA content of alveolar macrophages in the sputum. Dumbbell-shaped nuclei were frequently seen but only a few of them divided amitotically into small twin nuclei of more or less unequal size with corresponding pseudo-haploid DNA values. Tumor cells in the lung cancer patient imitated atypical alveolar macrophages with phagocytosis and vacuolated cytoplasm. The DNA content of the nuclei corresponded to 2, 3-4, 6-8, 12, 14, 20 and 22 C. In many cells identical nuclei were lying very close together, probably as a consequence of short mitotic spindles. The fusion of a varying number of such nuclei may explain DNA values such as 3, 14, 20 and 22 C. The DNA variability did not appear to be due to alterations in synthesis or necrosis.

- 0737 INFLAMMATORY PAPILLARY HYPERPLASIA OF ORAL MUCOSA: REPORT OF 341 CASES. (E.) Bhaskar, S. N. (Walter Reed Army Med. Ctr., Washington, D.C.), J. D. Beasley, III and D. E. Cutright. *J Amer Dent Ass* 81(4):949-952, 1970.

A survey of 341 cases of inflammatory papillary hyperplasia was conducted to describe the natural history of the lesion which affects the oral mucosa and occurs most often in the maxilla. The majority of cases are associated with dentures; and the average age of patients suffering from inflammatory papillary hyperplasia is 40.2 years. The lesion shows pseudoepitheliomatous hyperplasia, keratin cysts, and keratin pearls; however dyskeratosis is not shown, and malignancy does not develop. Inflammatory papillary hyperplasia may resemble mucoepidermoid tumor, for the salivary glands are involved in some cases.

- 0738 TRANSFORMATION OF FIBROBLASTS BY ALLOGENEIC AND XENOGENIC TRANSPLANTS OF DEMINERALIZED TOOTH AND BONE. (E.) Huggins, C. (Ben May Lab. Cancer Res., U. Chicago, Ill.), S. Wiseman and A. H. Reddi. *J Exp Med* 132(6):1250-1258, 1970.

Demineralized tooth and bone powder was implanted s.c. in guinea pigs, female mice, or rats to study the transformation of host tissue caused by the xenogenic implants. Osteogenesis was demonstrated by histologic study and by detection of alkaline phosphatase in transplants. Rats given 10-15 mg of coarse tooth or bone powder (from rat) developed hard calcified conglomerates of 60-150 mg 1-3 wk; alkaline phosphatase content in the transplant increased steadily for 2 wk after implantation. Implanted demineralized dentin produced cartilage in rats after 6 days, and bone after 10 days. Cartilage and bone were not observed in guinea pig connection with any of the transplants studied except with osteogenic epithelia. Demineralized mouse dentin produced large amounts of bone and cartilage in mice whereas rat dentin produced these elements in only small amounts. However, dentin produced large amounts of bone in rat host.

- 0739 STUDIES ON ENZYMES OF GLYCOLYSIS AND THE GLUCOSE SHUNT IN PRECANCEROUS RAT LIVER IN HEPATOMAS. (Ger.) Sydow, G. (German Acad. Sci. Berlin,). *Arch Geschwulstforsch* 35(4):379-383, 1970.

Enzymes participating in glycolysis were investigated in the precancerous rat liver. These included aldolase, pyruvate kinase, lactate dehydrogenase, glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase; these enzyme activities were determined in precancerous and in normal livers, as well as in primary and transplanted hepatomas. No significant differences in enzyme activities were observed between normal precancerous livers. A decrease in lactate dehydrogenase and a marked decrease in glucose-6-phosphate dehydrogenase activities were the only two notable changes.

changes in primary hepatomas. Transplanted hepatomas, however, showed marked changes in almost all parameters, with a significant increase in pyruvate kinase activity in all tested tumors; the other enzymes varied according to the tumor line. The activity of the glycolytic enzymes does not show any correlation to the tumor growth, but may be due to the loss of a specific organ function.

0740 **INTESTINAL MUCOSAL HYPERPLASIA FOLLOWING INDUCED HYPERTHYROIDISM IN THE RAT. (E.)**

Wall, A. J. (Dept. Med. U. Chicago, Ill.), W. R. J. Middleton, A. G. E. Pearse and C. C. Booth. *Virchows Arch Zellpath* 6(2):79-87, 1970.

The histological and histochemical changes which occur in the small intestine following the induction of hyperthyroidism (thyroid powder) were observed in the rat. The weight (mg/cm) of the small intestine was heavier in the hyperthyroid animal (83.2) than in the control (61.6) with a greater increase in the mucosal component (40-56) than in the muscular layer (15-20). The mucosal protein content was increased (6.11 to 7.84 mg/cm) and both villous height and total mucosal thickness were increased in the jejunum while only villous height was increased in the ileum. Height of the microvilli of the jejunal surface epithelium increased by 30% in the hyperthyroid animals. Enzyme changes were found chiefly at the brush border of the jejunal epithelium with an increase of acid phosphatase, ATP-ase, and thiamine pyrophosphatase in all 8 animals studied. Monamine oxidase activity was moderately reduced in the jejunum, ileum, and liver of the hyperthyroid rat.

0741 **CARCINOMA ON THE SITE OF COMPENSATORY HYPERPLASIA IN ADRENAL CORTEX REGENERATION.**

(Ger.) Rückert, U. (Surg. U. Heidelberg, Germany). *Chirurg* 41(9):417-419, 1970.

The underlying pathoanatomical changes in the adrenal glands leading to Cushing's syndrome, is most frequently due to a bilateral hyperplasia, which stems from a basophilic adenoma of the anterior pituitary gland. The adrenocortical carcinomas may have properties of various grades of malignancy and cell differentiation. A case is presented of a 15-yr-old boy in whom Cushing's disease developed from a bilateral hyperplasia of the adrenal cortex which was diffuse and micronodular. After subtotal bilateral adrenalectomy, there was a temporary remission under hydrocortisone replacement therapy. The remission lasted for two years after which the 17-hydroxycorticoid excretion increased to 14.0 mg/24 hr and 17-ketosteroids increased to 18.6 mg/24 hr during the subsequent 3 yr, although the therapy was discontinued. At this time surgical intervention revealed a differentiated carcinoma at the site of the subtotally resected gland. The postoperative recovery, with hormonal replacement therapy, was uneventful, but the patient died 6 months later from acute myocardial failure. Malignant degeneration in benign hyperplasia of the adrenal cortex could be avoided by bilateral total adrenalectomy.

0742 **STUDY ON THE PATHOGENESIS OF CERVICAL POLYPS. (Sp.)** Nogales Fernandez, F. (Fac. Med. Madrid, Spain) and A. Tarancon Martinez. *Acta Gynec* 21(9):659-674, 1970.

Biopsies performed on 41,000 gynecological cases (at the Dept. of Gynecology of Madrid Univ., records from January 1970) revealed 1,901 (4.6%) cervical polyps. Of these, 581 (31%) surgical samples were compared with the functional condition of the endometrium in an attempt to explore the etiological factors contributing to the occurrence of these tumors. The surgical samples revealed 44 (7.6%) proliferative normal endometria, 119 (20.5%) normal secretory endometria, 47 (8.1%) endometria with progestational insufficiency, 317 (54.6%) diffuse or cystic hyperplastic endometria, and 54 (9.3%) atrophic endometria. The high correlation between cervical polyps and glandular endometrial hyperplasia associated with progestational insufficiency (total of 63%), and the maximal age incidence between 35-56 yr suggested that hyperestrinism could be among the leading factors in the etiology of these tumors.

0743 **ENDOMETRIAL HYPERPLASIA IN YOUNG WOMEN. (E.)** Chamlian, D. L. (Armed Forces Inst. Path., Washington, D.C.) and H. B. Taylor. *Obstet Gynec* 36(5):659-666, 1970.

The pathology of endometrial hyperplasia was studied in 97 women under 36 yr old. In 24 cases, hyperplasia involved sclerocystic ovaries, an association consistent with the Stein-Leventhal syndrome. In 14 patients, initial endometrial hyperplasia progressed to adenocarcinoma in 1-14 yr after the original diagnosis; and absence of corpora lutea and albicantia were among the salient findings in these patients. In all 97 cases fertility was low, and only 26 patients conceived in the years after endometrial hyperplasia was diagnosed; only 20 of the patients who conceived carried their pregnancies to term. Thirty-seven patients continued to have menstrual irregularities from 1-30 yr after endometrial hyperplasia was diagnosed.

0744 **CERVICAL CYTOLOGY IN THE TEEN-AGE PATIENT. (E.)** Kaufman, R. H. (Baylor Coll. Med., Houston, Texas), R. E. Burmeister and H. J. Spjut. *Amer J Obstet Gynec* 108(4):515-519, 1970.

Cytological evidence of carcinoma was studied in cervicovaginal smears prepared from 10,246 women under 20 yr-of-age. Moderate dysplasia was diagnosed in 175 cases, squamous cell carcinoma *in situ* in 13; severe dysplasia was indicated in 45 smears. These findings imply that 23 of 1000 patients screened had significant dysplasia in their smears. Where conization biopsy was performed on patients in follow-up examinations (17 cases), carcinoma *in situ* was found in 4 instances, severe dysplasia in 11. In the cases of 76 patients, of whom 10 had manifested severe dysplasia, 2 follow-up smears taken after the initial diagnosis of abnormality were aberration-negative. The patients studied

were from indigent backgrounds, and 75% of them were obstetrics cases, facts which suggest that the high incidence of cervical atypia in the population studied were related to the known association of cervical carcinoma with early onset of coitus and low socioeconomic status.

- 0745 SPONTANEOUS *IN VITRO* NEOPLASTIC TRANSFORMATION OF ADULT HUMAN PROSTATIC EPITHELIUM. (E.) Fraley, E. E. (Dept. Surg., U. Minnesota, Minneapolis), S. Ecker and M. M. Vincent. *Science* 170(3957):540-542, 1970.

Studies with explants from a benign prostatic adenoma from a human patient that have had an unusually long life *in vitro*, having undergone more than 200 passages for 4 yr, are reported. The prostate gland from which the cell line was derived exhibited marked glandular hyperplasia with some areas of squamous metaplasia; however, no malignancy could be demonstrated. Cell suspension from various passages of the cell line caused solid tumors when injected into the cheek pouches of newborn hamsters which had been exposed to whole-body irradiation; tumors were composed of anaplastic epithelioid cells, and invaded surrounding connective tissue, although distant metastases did not occur. Neither mycoplasma nor viruses have been detected in cultures of the prostate cell line. This spontaneous transformation noted in cells from a benign prostatic adenoma indicate that such tissues may be pre-malignant.

- 0746 EMBRYONAL ADENOCARCINOMA IN THE PREPUBERTAL TESTIS: A CLINICOPATHOLOGIC STUDY OF 18 CASES. (E.) Young, P. G. (St. Joseph's Hosp. Lexington, Kentucky), B. M. Mount, F. W. Foote, Jr. and W. F. Whitmore. *Cancer* 26(5):1065-1075, 1970.

The treatment and histogenesis of embryonal adenocarcinoma were examined with a review of the clinicopathologic findings in 18 afflicted children. The most suggestive clinical sign was a firm non-tender testicular mass (2-12 cm) and was initially detected by the mother in 14 of the cases (78% of the cases occurred in infants under 2 years of age). Two cases in this study demonstrated that the tumor may occur in the infant and prepubertal child testis in association with teratomatous growth (previously recorded only in adult cases). The small number of cases reviewed prohibits assessment of the factors influencing survival but clinical Stage A lesions subjected to lymphadenectomy had a 75% survival rate compared to 83% without node dissection, and a Stage C case in which radical surgery was performed suggested a potential favorable effect on prognosis in selected cases. All retroperitoneal lymph nodes were negative in State A cases subjected to lymphadenectomy so that retroperitoneal lymph node dissection or irradiation may be replaced with chemotherapy. Embryonal adenocarcinoma is a testicular tumor of primordial germ cell origin which differs from the

adult embryonal carcinoma in its appearance and behavior although the histogenesis may be the same.

0750 EPIDEMIOLOGY AND DETECTION OF BRONCHIAL CARCINOMA. (Ger.) Trendelenburg, F. (Med. J. Clin. Homburg, Germany) and W. Mall. *Internist* 11(9):303-317, 1970.

Bronchial carcinoma occurs most frequently in industrial cities and has the worst prognosis among carcinomas. The 5-yr life expectancy among all the bronchial carcinomas is between 5 and 16-17%, depending upon the time of discovery, the localization, treatment (operability) and malignancy. Operability is very much dependent upon the localization (peripheral or central), but the methods for tracing the focal area are not yet satisfactory. The intensity of the exposure of the lungs to contaminants is a major factor in the formation of carcinoma, and inhalation of smoke has been shown to be noxious, particularly cigarette smoking. Other noxious substances to which people are exposed are arsenic (formerly used in insecticides), asbestos (in the construction industry), chromium (in alloys and dyes), nickel (in alloys and dyes), isopropyl alcohol (poison gas) and by-products of coal combustion. The detection of exfoliation of the malignant cells in bronchial secretion and radiological detection provide the earliest diagnosis of bronchial carcinoma. A questionnaire regarding smoking, including questions related to possible malignancy, is presented.

0751 SCREENING FOR LUNG CANCER HIGH-RISK GROUPS. (E.) Kubik, A. (Tuberc. Respiratory Dis. Res. Inst. Prague, Czechoslovakia). *Brit Med J* 2(5710):666, 1970.

Patient interviews concerning smoking habits, cough, expectoration of sputum, blood spitting and respiratory infections were conducted on male patients aged 40-64 in an attempt to identify high-risk lung cancer groups in the Kolin district, Czechoslovakia. Information on lung cancer incidence subsequent to the interviews was obtained from notification cards, death certificates and chest clinic and hospital records. The group interviewed included 52% cigarette smokers, and 61 subsequently proven lung cancer cases (an incidence of 1.41/1000/yr.) In the group of 2707 smokers who had smoked 200,000 cigarettes and over there was a 4.64/1000 annual incidence of lung cancer; in the group of 3627 smokers who had smoked less than 200,000 cigarettes, and in the group of 1487 cigarette ex-smokers, the annual incidence was 0.87, and 0.96/1000, resp. The risk for nonsmokers was less than 0.07/1000. Persons with a chronic cough were at a 5 times greater risk than non-coughers. The annual incidence of lung cancer for men with a history of sputum expectoration was 3.30/1000, and 4.39/1000 for those with worsening coughs, and 10.20/1000 for those reporting hemoptysis.

0752 OSTEOGENIC SARCOMA. (E.) Potdar, G. G. (Tata Mem. Hosp., Bombay, India). *J Postgrad Med* 16(3):142-148, 1970.

The incidence and pathology of osteogenic sarcomas were investigated in a series of 169 cases. Tumors were most frequently located around the knee joint, with the maxilla and humerus being affected in 24 cases. The average age of patients was 19.8 yr, osteogenic sarcoma being generally more common in the second decade of life than at any other time. Males were affected more often than females (104 to 65). Only 1 case in the series showed sarcoma associated with Paget's disease and in no case was there any history of radiation therapy; however, in 48 cases there was history of trauma occurring prior to the onset of symptoms. Lungs were the most frequent site of metastasis (92 cases), with skeletal and lymph node metastasis occurring less commonly. Tumors involved the bone metaphysis and adjoining portion of the diaphysis only, with the epiphysis affected only in the later stages of the disease. Microscopically, the tumors showed variable preponderance of fibrous, cartilaginous or osteoid tissue; all tumor cells formed new bone. Surgery was the treatment of choice for osteogenic sarcoma in this series; pulmonary metastasis was common following surgery or radiation therapy. (5 references).

0753 HYDATIDIFORM MOLE, INVASIVE MOLE AND CHORIOCARCINOMA IN SWEDEN 1958-1965. (E.) Ringertz, N. (Karolinska Inst., Stockholm, Sweden). *Acta Obstet Gynec Scand* 49(2):195-203, 1970.

A review was conducted of the occurrence of hydatidiform mole, invasive mole, and choriocarcinoma in Sweden from 1958-1965, which emphasized the pathology and frequency of these conditions. The case material included 631 cases of hydatidiform mole not followed by malignancy, 13 cases of invasive mole, 10 cases of choriocarcinoma following hydatidiform mole, and 14 cases of choriocarcinoma without preceding mole. Frequencies for these conditions were calculated on the number of pregnancies in Sweden during the test period. Hydatidiform mole occurred with a frequency of 1:1,560 pregnancies; invasive mole with a frequency of 1:77,000; and choriocarcinoma with a frequency of 1:41,000. In the case of both benign mole and malignant conditions, frequencies rise significantly in women at the age of 40 yr. Women who had been pregnant 3 or more times had a higher incidence of choriocarcinoma without associated mole (43%), while women with a single pregnancy had a higher incidence of mole followed by malignancy (30%). Invasive mole was defined as having villous structures within myometrial vessels. Choriocarcinoma was diagnosed only in cases showing clearly destructive myometrial invasion by chorionic elements in the absence of villous structures. The clinical course of invasive mole cases included lung metastases in 3 cases; choriocarcinoma metastasized to the lung in 13 of 24 cases, and vaginal metastases were recorded in 2 choriocarcinoma patients. Survival data indicated that all patients with invasive mole continued to live symptom-free, while 17 of 24 choriocarcinoma patients died within 5 yr.

- 0754 MALIGNANCY AND RECORDS OF CANCER PATIENTS
IN THE PROVINCE OF KURGAN. (Rus.)
Goldberg, B. I. (Reg. Oncol. Dispen., Kurgan, USSR).
Vop Onkol 16(8):76-80, 1970.

The cancer incidence in the province of Kurgan was 181 per 100,000 population according to the 1962-1966 records. Of 5435 malignancies in males 27% gastric, 20% pulmonary, 12% lip, 9% skin and 3% bladder cancers were reported; in females 25% gastric, 20% cervical, 12% skin, 6% mammary gland and 4% lung cancer had occurred. The highest incidence of cancer occurred at the age 50-59 yr, and 88% of the malignancies occurred above the age of 40. Female susceptibility to cancer was higher than males from 5-40 yr-of-age, equal to that of males at 40-49 yr and lower than males above the age of 49 yr. In the total population of the U.S.S.R., the cancer incidence in males was 70 gastric, 53 pulmonary, 30 lip, 22 skin, 7 esophagus, and 7 bladder malignancies/100,000 population; in females 43 gastric, 37 cervical, 21 skin, 11 breast, 7 pulmonary, and 5 hepatobiliary malignancies/100,000 population were recorded. Of all malignancies 1.6% occurred in children, the incidence for age 0-19 yr being 8/100,000.

- 0755 CANCER IN CHILDREN. (Fr.) Jeliu, G. (Fac.
Med. U. Montreal, Quebec, Canada). *Un
Med Canada* 99(11):2054-2057, 1970.

According to the records of the federal statistics bureau 25,432 patients died of cancer in Canada in 1963, of which 603 (2.1%) were children 1-19 yr-of-age. Cancer occupied the 2nd place (after accidents) among the main causes of child mortality. This figure was much higher in 1967 in Quebec (2.7% for the same age group) than throughout Canada. Leukemia was the most frequent (35-50%) among childhood malignancies while brain cancer incidence was highest among the solid tumors. Neuroblastoma, Wilms' tumor, soft tissue sarcoma, osteosarcoma, and lymphomas constituted 5-10% each. The major types of cancers found in children differed from those found in adults in whom epithelial malignancies were predominant.

- 0756 HODGKIN'S DISEASE IN THE FIRST DECADE OF
LIFE. (E.) Rappaport, H. (Pritzker Sch.
Med., U. Chicago, Ill.) and S. B. Strum. *Pediatrics*
46(5):748-759, 1970.

A study of 35 case reports of children with Hodgkin's disease showed that all were more than 3 yr-of-age, and the longest survival periods were 9 and 9.8 yr. Ninety-one percent of the patients were males, 94% were Caucasian and 6% (2 patients) were Black. In 30 of 31 classifiable cases, the histologic sections showed either nodular sclerosing Hodgkin's disease or Hodgkin's disease with lymphocytic predominance. Regardless of classification, a striking preponderance of mature lymphocytes in tissue sections and a scarcity of Sternberg-Reed cells were evident in most cases. The hypothesis that a particular host response characterizes Hodgkin's disease in the young is suggested by these findings.

- 0757 FREQUENCY AND AGE DISTRIBUTION OF EPSTEIN-BARR VIRUS ANTIBODIES IN FRANCE. A PRELIMINARY EPIDEMIOLOGICAL INVESTIGATION. (Fr.)
Sohier, R. (Natl. Inst. Sanit., Med. Res., Lyon, France). *Path Biol* 18(15-18):707-711, 1970.

Indirect immunofluorescence tests were performed on the sera of 279 patients hospitalized for various conditions in order to detect and titrate antibodies to the Epstein-Barr virus. The percentage of positive reactions (> 10) in relation to age suggested that between 7 and 12 months of age, 12.5% of children had acquired antibodies, and between 12 and 24 months 47.9% had acquired antibodies. The percentages increased progressively to reach between 75% and 88% between the ages of 11 and 69 years, except for the 31-40 age group which is being investigated further. Beyond the age of 60 years 92% of the reactions were positive. Antibody titer equal to or greater than 160 found in the 12.5% sera examined and in 19.5% of the positive reactions might have been due to recent infections (e.g. infectious mononucleosis).

- 0758 AN EPIDEMIOLOGICAL STUDY OF THE EPSTEIN-BARR HERPES VIRUS IN FRANCE: FREQUENCY AND AGE DISTRIBUTION OF ANTIBODIES IN THE REGION OF PARIS. (Fr.) Chuat, J. C. (Hosp. St. Louis, Paris, France), F. Lasquelle and M. Boiron. *Path Biol* 18(15-18):713-717, 1970.

Serum samples were taken from 533 children and adults in Paris between 1965-1968, and indirect immunofluorescence tests were performed on them to detect antibodies to the Epstein-Barr virus. Antibodies were found in 50% of the children by the age of 5 yr and the proportion of reactive sera rose to 2/3 in 15 yr old children. The antibody titer was determined in 168 of the sera and was generally found higher in the youngest (1-5 yr) and during the acute stage of infectious mononucleosis. A stable titer of Epstein-Barr virus antibodies was found in individuals whose sera were titrated at yearly intervals. The high incidence of high titers of Epstein-Barr virus antibodies in children below 10 yr-of-age seemed to indicate that some viral infection occurred during childhood which bore no strict relationship to infectious mononucleosis.

- 0759 POLYPS AND CARCINOMA OF THE LARGE BOWEL IN THE SOUTH AFRICAN BANTU. (E.) Bremner, G. (Baragwanath Hosp., Johannesburg, Union of South Africa) and L. V. Ackerman. *Cancer* 26(5):991-995, 1970.

The incidence of carcinoma of the large bowel and neoplastic polyps of the bowel was investigated in the Bantu population in South Africa. In this population, cancer of the large bowel was extremely rare, only 45 cases having been admitted to this African hospital in the 12-yr study period (the hospital admitted 77,997 patients in 1967-68). Adenomatous polyps were also rare, a series of 96 patients showing no instance of polyps, and a review of 14,000 autopsies revealing no mention of

adenomatous polyps. This low incidence of cancer of the large bowel is probably an environmental feature rather than a genetic trait; in contrast to the United States (which has the highest rate of cancer of the large bowel on record) the Bantu of South Africa has an extremely bulky diet. The Bantu diet depends on maize, of which the annual consumption averages 839 l. Associated with this diet is an increased frequency of defecation with the mean time of transversal of the digesta about 3 times faster in the Bantu than in whites. The bulk of the Bantu diet and the frequency of defecation may account for the low incidence of carcinoma of the large bowel and of adenomatous polyps in these people.

0760 INCIDENCE OF MALIGNANT NEOPLASMS IN FAMILIES OF PATIENTS WITH ESOPHAGEAL CANCER. (Rus.) Satpayeva, R. A. (Kazach Res. Inst. Oncol and Radiol., Alma-Ata, USSR), and G. V. Tarasova. *Vop Onkol* 16(6):3-6, 1970.

Eighty nine cases of cancer (80 of which were cancer of the esophagus) were found in the genealogy of 75 families of esophageal cancer patients. Sixty-five (81%) of these esophageal cancers occurred in direct relatives (mother, father, son, daughter, grandparents, nephews); esophageal cancer occurred in 15 husbands or wives of such patients. Among the relatives of a group of 425 patients from Kazakhstan 70 (16.5%) exhibited esophageal cancer; of the relatives of a control group of 877 subjects 75 (8.5%) were cancer patients with only 2 cases (0.2%) of familial cancer. The incidence of esophageal cancer in the families of esophageal cancer patients from the Gur'yevsk region was 42.5% and 21.6% among the control group (9 times higher than in other regions of Kazakhstan). There seemed to be an inherited predisposition towards esophageal cancer possibly due to food habits and specific way of life.

0761 GEOGRAPHIC AND SECULAR VARIATION IN MORTALITY FROM MALIGNANT DISEASE IN OKLAHOMA: 1956-1965. (E.) Assal, N. R. (U. Oklahoma Sch. Hlth., Oklahoma City) and R. D. Lindeman. *J Okla-homa St Med Ass* 63(10):469-480, 1970.

An epidemiological study of deaths from cancer of the hematopoietic system in Oklahoma from 1956-1965 was conducted. The most common hematopoietic malignancies recorded were leukemia (accounting for 1057 deaths among white males) and lymphosarcoma-reticulosarcoma (accounting for 421 deaths among white males.) Deaths from multiple myeloma had increased during the period studied (death rates increasing from 7.1 in 1956-1960 to 10.1/100,000 in 1961-1965); other malignancies showed no increase in frequency of death rates. The average age-specific death rates for all conditions showed increases with age, and there was an early peak in leukemia deaths in the under-5-yr age group. Death rates were higher for whites in all disease categories than for non-whites. Although death rates for leukemia in white males showed no correlation with

degree of urbanization of residence, death rates for white females from leukemia were higher for metropolitan residents (death rates of 6.7 and 5.9/100,000 for "metropolitan" and "non-metropolitan" residents, resp.). Leukemia deaths showed clusters in western counties of the state, while deaths from lymphoma among white females cluster in the north-east.

0762 POPULATION KINETICS OF CARCINOMA CELLS, CAPILLARY ENDOTHELIAL CELLS AND FIBROBLASTS IN A TRANSPLANTED MOUSE MAMMARY TUMOR. (E.) Tannock, I. F. (Radiobiol. Inst., TNO, Rijswijk, Netherlands). *Cancer Res* 30(10):2470-2476, 1970.

Mice received s.c. injections of 10^5 cells of mouse mammary tumors, and tumor sections were subsequently obtained and stained for the purpose of observing the kinetic parameters in populations of capillary endothelial cells, fibroblasts and parenchymal cells; parameters were estimated by thymidine labeling techniques and by autoradiography. The mean thymidine labeling index of carcinoma cells was 35%. Mitotic index, labeling index, and mean grain count per labeled cell decreased with distance of carcinoma cells from a capillary. Values for these 3 parameters decreased from 4.3, 50.0, and 40, resp., for the region near the blood vessel, to 0.6, 10.3, and 10, resp., for the region near a site of necrosis. Migration of cells from regions of rapid proliferation near blood vessels to regions of slow or nonproliferation near necrosis was observed. The median cell cycle time was 13 hr, and the growth fraction from a repeated thymidine labeling experiment was about 50%, giving a turnover time for the carcinoma cells of about 22 hr. The mean thymidine labeling indices of capillary endothelial cells and fibroblasts were 11.4 and 9.1%, resp.; the turnover times for the endothelial cells was 50-60 hr and 70-80 hr for the fibroblasts. The mean labeling index of capillary endothelial cells remained quite constant between 10 and 40 hr after a single injection of tritiated thymidine, indicating that capillary endothelial cells are not derived from a faster-proliferating precursor population. The division of endothelial cells within the capillary walls appeared to condition the extension of the capillary network in the growing tumor.

0763 CANCER CELL DISSEMINATION IN BLOOD AND METASTASIS OF WALKER'S CARCINOMA IMPLANTS. (Rus.) Sukovatykh, L. S. (Res. Inst. Oncol. BSSR Minist. Publ. Hlth., Minsk, USSR) M. Ye. Fisher, M. Yu. Makkaveyeva, S. Z. Fradkyn, A. A. Mashevskiy, B. M. El'Perin and M. P. Stankevich. *Vop Onkol* 16(6):60-63, 1970.

The dynamics of growth and development of metastases of Walker's carcinoma were studied following partial transplantation (200 mg segments) into the gastric wall of 100 Wistar male rats. The tumor diameter reached 0.6-0.7 cm at 6-7 days, 1 cm at 9 days, 2 cm at 12 days, 3 cm at 18 days and 4 cm at 24 days after transplantation. No further growth of tumor

was noticed thereafter due to partial necrosis. Initial growth occurred at muscle levels (up to the 19th day) and mucosal penetration started on the 20th day after transplantation. An enlargement of lymph nodes could be noticed along with the growth of the tumor. Hyperplasia of the paraaortal lymph nodes was observed on the 9th day, and metastases occurred on the 13th day after transplantation. Tumor nodules in the liver and metastases in the paratracheal lymph nodes appeared at 19 days and in the spleen at 20 days after transplantation. Tumor cell blood dissemination began 6 days after transplantation and tumor cell blood levels increased along with the development of metastases. The presence of tumor cells in the blood in the early stages of tumor growth seemed indicative of the generalized nature of this process and their high capacity for dissemination throughout the blood stream, which occurred prior to the development of metastases in the regional lymph nodes.

- 0764 THE HISTOPATHOLOGY OF BRONCHOGENIC CARCINOMA AND ITS RELATION TO GROWTH RATE, METASTASIS, AND PROGNOSIS. (E.) Weiss, W. (Hahnemann Med. Coll., Philadelphia, Pa.), K. R. Boucot and D. A. Cooper. *Cancer* 26(5):965-970, 1970.

The histopathology of 161 cases of proved bronchogenic carcinoma was examined by comparing the classifications assigned by a panel of 3 pathologists (using a modified World Health Organization classification) with the diagnoses of hospital pathologists. Agreement was 84% for cases classified as squamous cell carcinoma, 67% for undifferentiated carcinoma, and 78% for adenocarcinoma. Unanimity among the 3 panel pathologists occurred in only 40% of the 161 cases and was more frequent in cases where 2 or more histological sections were available for examination and where there was a lower degree of anaplasia. Although squamous cell carcinomas have a doubling time of less than 6 months and adenocarcinomas have a doubling time of more than 6 months, the 5-yr survival rates for patients with either cancer is the same (11-12%), because squamous cell carcinomas have lower metastasis rates (63%) that adenocarcinomas (100%).

769 STRAIN DIFFERENCES IN RESPONSE OF THE MOUSE MAMMARY GLAND TO HORMONES *IN VITRO*. (E.) Singh, D. V. (Michigan Cancer Found., Detroit), B. DeOme and H. A. Bern. *J Nat Cancer Inst* 45(4): 67-675, 1970.

The effect of *in vivo* pretreatment with hormones on the *in vitro* lobuloalveolar development in mouse mammary glands from different strains was tested. Female mice of 7 strains were given daily s.c. injections of 1.0 µg estradiol-17β and 1 mg of progesterone for 5, 9, and 15 days, after which mammary glands were excised and cultured with estradiol, progesterone, aldosterone, prolactin, growth hormone, and insulin, 0.001, 1.0, 1.0, 5.0, 5.0 and 0.0 µg/ml, resp. After a minimum period for pretreatment, the mammary glands were cultured in media without estradiol and progesterone. The R111 and 1st mouse strains required 5 days of pretreatment *in vivo* with estradiol and progesterone to show development *in vitro*; DBA/2, C3H, and BALB/c strains required 9 days; C57BL and A strains required 15 days. A greater length of pretreatment was correlated with the absence of the inherited hormonal influence, a hypothesis which proposes that the differences in tumor incidence in mice of various strains is related to genetically determined hormonal background. The minimal hormonal requirements *in vitro* varied with different strains. A concentration of 0.1 µg aldosterone/ml of medium was adequate for all strains except the A, which needed 1.0 µg/ml. Insulin requirements ranged from 0.5-2.5 µg/ml; prolactin and growth hormone requirements ranged from 0.1-5.0 µg/ml. There was no correlation between *in vitro* requirements for lobuloalveolar differentiation and inherited hormonal influence.

770 INCREASED INCIDENCE OF SPONTANEOUS MAMMARY TUMORS IN FEMALE RATS WITH INDUCED HYPOTHALAMIC LESIONS. (E.) Welsch, C. W. (Dept. Anat., Michigan St. U., East Lansing), H. Nagasawa and J. Sites. *Cancer Res* 30(9):2310-2313, 1970.

Unilateral electrolytic lesions were placed in the median eminence of the hypothalamus of multi-gestous mammary tumor-free rats, and a sham procedure was performed on a control group, to investigate the effect of induced hypothalamic lesions on mammary tumor incidence in rats. After 25 wk the animals were killed, the number of palpable mammary tumors was determined, and blood was withdrawn for prolactin analysis by radioimmunoassay. Mammary tumor incidence and blood prolactin levels were significantly increased in median eminence-lesioned rats (12/23, 52%; 179.8 ng/ml) in contrast to the controls (4/21, 19%; 50.9 ng/ml). These results demonstrate that disruption of the final common pathway from the hypothalamus to the anterior pituitary can significantly enhance spontaneous mammary tumorigenesis in the female rat. The role of prolactin as the principal hormonal factor in mammary oncogenesis in the rat is supported by the finding of increased blood levels of prolactin in median eminence-lesioned rats.

0771 SEROLOGY IN THE STUDY OF THE RELATIONSHIP BETWEEN *S. HAEMATOBIIUM* INFESTATION AND CANCER OF THE URINARY BLADDER. (E.) Halawani, A. (Coll. Med. U. Baghdad, Iraq), M. Al-Waidh and S. M. Said. *Brit J Urol* 42(5):580-585, 1970.

The association of schistosomiasis (*Schistosoma haematobium*) and carcinoma of the urinary bladder was investigated by means of serological tests in 52 subjects with bladder cancer in an area of Iraq which is endemic for schistosomiasis. Although 40 of the patients had a history of schistosomiasis only 6 excreted *S. haematobium* ova in the urine. Complement fixation tests and circumovum precipitin tests were performed to determine the extent of the association of schistosomal infestation with cancer of the bladder. Of 52 patients, 46 showed positive complement fixation tests, while 4 were negative and 2 gave an anti-complementary reaction. Forty-four out of 45 patients of the same series were positive for the circumovum precipitin test. All the 6 patients who passed ova in their urine were positive for both serological tests. The long duration of *S. haematobium* infestation in these cases may account for the absence of ova in the urine of the majority of patients.

0772 SYMPTOMS AND PATHOLOGY OF MULTIPLE MALIGNANCIES (163 cases). (Ger.) Becker, H. (Path. Inst. U. Graz, Germany). *Med Klin* 65(41): 1775-1781, 1970.

Multiple malignancy discovered at autopsy in 132 cases (and in 31 non autopsied cases) is described. The majority of these cases comprised males and a large group of stillborn and newborn infants. The males outnumbered the females in the 45-50 yr age bracket. Malignant neoplasm was evaluated in terms of carcinoma, sarcoma, glioma, hemoblastosis and neoplastic reticulosis. The results are tabulated according to simultaneous or sequential occurrence, localization, and succession. This multiple occurrence was usually associated with paired organs, and was due either to some endogenous tissue anomaly or subsequent to some elective exogenous damage. Patients with double malignancies do not fall into any specific age group. The patient with carcinoma does not seem to be any more susceptible to a second carcinoma (after the first was treated) than is the normal population (with the exception of carcinoma of the large intestine). The incidence of a second lesion is about 1%; the lesion is usually located near and occurs within 5 yr of the primary lesion.

0773 PLASMA GROWTH HORMONE AND HYPERTROPHIC OSTEOARTHROPATHY IN CARCINOMA OF THE BRONCHUS. (E.) Dupont, B. (U. Hosp. Copenhagen, Denmark), I. Hoyer, S. Borgeskov and J. Nerup. *Acta Med Scand* 188(1-2):25-30, 1970.

A syndrome involving hypertrophic osteoarthropathy and carcinoma of the bronchus in 3 patients is reported. The patients, 2 men and 1 woman, aged 54, 67 and 69 yr, showed edema of hands and feet

and, in 1 case, signs of acromegaly. Plasma growth hormone (HGH) assays were performed under fasting conditions and during glucose tolerance tests before and after operation on the patients' lung tumors; in 2 cases HGH levels were normal both before and after surgery, and in 1 case fasting HGH levels before surgery were elevated (20 ng/ml of plasma). In this case, elevated HGH may have resulted from autonomous secretion. It did not appear likely that hypertrophic osteoarthropathy was the result of increased production of HGH. Possibly HGH or HGH-like substances were produced by malignant lung tumors in these patients.

- 0774 GONADOTROPHIN-SECRETING BRONCHIAL CARCINOMA: ABERRANT ENDOCRINE ACTIVITY OR TROPHOBLASTIC DIFFERENTIATION? (E.) Beck, J. S. (Dept. Path., U. Aberdeen, Scotland), I. B. Porteous and J. L. Ulliot. *J Path* 101(1):59-62, 1970.

Four bronchial tumors which secreted a substance with gonadotrophin activity were studied to determine whether the tumors showed evidence of trophoblastic differentiation. Tumor tissue was stained using an indirect immunofluorescent technique which reveals human placental lactogen, a reliable indicator of trophoblastic differentiation. The primary and metastatic tumors from the patients were composed primarily of large-celled anaplastic carcinoma with marked pleomorphism and numerous tumor giant cells. Immunofluorescent staining failed to show any human placental lactogen or growth hormone in any of the tumor tissues studied. The tumors apparently were demonstrating aberrant endocrine activity, inasmuch as there was no evidence of the cellular differentiation ordinarily associated with synthesis and secretion of gonadotrophic hormones.

- 0775 METABOLIC AND BIOSYNTHETIC FEATURES OF LYMPHOCYTES FROM PATIENTS WITH DIABETES MELLITUS: SIMILARITIES TO LYMPHOCYTES IN CHRONIC LYMPHOCYTIC LEUKAEMIA. (E.) Brody, J. I. (Grad. Hosp. U. Pennsylvania, Philadelphia) and K. Merlie. *Brit J Haemat* 19(2):193-201, 1970.

Glucose metabolism and DNA synthesis was investigated in lymphocytes from patients with chronic lymphocytic leukemia and diabetes mellitus. Glucose metabolism was assayed by measuring the extent of evolution of $^{14}\text{CO}_2$ and the production of radioactive glycolytic intermediates from $1\text{-}^{14}\text{C}$ -glucose in the lymphocytes; DNA synthesis was measured by observing the incorporation by the same cells of ^{14}C -thymidine. Most diabetic lymphocytes showed depressed glucose metabolism through the direct oxidative pathway, together with depressed incorporation of labeled thymidine. Normal values for $^{14}\text{CO}_2$ evolution were $9.9 \text{ nmole of } 1\text{-}^{14}\text{C}\text{-glucose} / 1.25 \times 10^7 \text{ cells} / 3 \text{ hr}$; diabetic cells in 1 representative patient showed values of $1.9 \text{ nmole of } 1\text{-}^{14}\text{C}\text{-glucose} / 1.25 \times 10^7 \text{ cells} / 3 \text{ hr}$. Normal and diabetic cell values for thymidine incorporation were 958 and 628 cpm/ 10^7 cells, resp. In leukemic cells, glucose metabolism and thymidine incorporation were similarly depressed. In all lymphocytes assayed,

a correlative and semiquantitative relationship seen between the amount of glucose passing through the hexose monophosphate shunt (which generates NADPH) and the synthesis of DNA, a process which requires NADPH for the reduction of oxyribonucleotides to deoxyribonucleotides. The normal antigenic recognition and satisfactory initiation of the immune responses, mediated by the lymphocytes, may be based on some metabolic function, which is distributed in leukemic and diabetic conditions.

- 0776 CARCINOMA OF THE OESOPHAGUS WITH TYLOSIS (E.) Harper, P. S. (Nuffield Unit Medical Genet., U. Liverpool, England), R. M. J. Harper, A. W. Howel-Evans. *Quart J Med* 39(155):317-333, 1970.

Chromosome analysis and autopsy reports were studied in members of a family in which there is a correlation between tylosis and cancer of the esophagus; of 8 tylotic members dying since 1958, were found to have died of esophageal carcinoma; only tylotic members have exhibited esophageal carcinoma. Onset of tylosis in the family was sometimes delayed until middle age; and tylotic women were at equal risk with men of developing cancer of the esophagus. The fact that no instances of carcinoma of the esophagus occurring in children of non-tylotic parents have been recorded suggests that both carcinoma and tylosis are controlled by a single gene locus. Tylotic and non-tylotic parents showed comparable fertility, and major chromosomal abnormalities were found to a tylotic subjects.

- 0777 VITILIGO AND GASTRIC CARCINOMA. (E.) Wright, P. D. (Roy. Victoria Infirmary, Newcastle, England), C. W. Venables and R. P. R. Barber. *Brit Med J* 3(5715):148, 1970.

Anemia and vitiligo in a 46-yr-old brickyard worker were associated with gastric carcinoma. The patient presented with an enlarged nodular thyroid gland and exophthalmos together with vitiligo; surgery revealed an infiltrating carcinoma of stomach involving adjacent lymph nodes. The lesion was a moderately well-differentiated adenocarcinoma penetrating the stomach wall. The occurrence of stomach cancer in this patient with vitiligo may be more than fortuitous, given the high correlation of pernicious anemia with vitiligo and the high correlation of pernicious anemia with gastric carcinoma.

- 0778 LYMPHATICS IN MALIGNANT MELANOMA. (German) Nodl, F. (Surg. Clin. U. Saarlandes, Homburg, Germany). *Arch Klin Exp Derm* 238(2):169, 1970.

In malignant melanoma the lymphatic vessels become enlarged at an early stage in the tumor formation shortly after the primary tumor has broken through the epithelial layer, and the cell-rich infiltrates, atrophies and metastases begin to form. The a

ion that melanoma contains only one type of cell has been disproved, and specific antibodies have been found only in localized malignant melanoma. The case of a 75-yr-old patient with such melanoma is presented. Melanoma cells and micrometastases were found in the lymphatic vessels. Histological examination revealed cells which were distinguishable from the primary tumors. The hydrodynamic character of the lymph stream appears to influence the spread of the melanoma cells. The examination of the lymph is thus preferable to the blood stream for the detection of metastases.

0779 *IN VITRO* INDUCTION OF GRANULOCYTE DIFFERENTIATION IN HEMATOPOIETIC CELLS FROM LEUKEMIC AND NON-LEUKEMIC PATIENTS. (E.) Paran, M. (Weizmann Inst. Sci., Rehovot, Israel), L. Sachs, Y. Barak and P. Resnitzky. *Proc Nat Acad Sci* 67(3):1542-1549, 1970.

The conditions for the induction of granulocyte colonies from normal human bone marrow by human spleen-conditioned medium and the cloning efficiency and colony size with bone marrow and peripheral blood cells from leukemic and non-leukemic patients were determined. Human spleen-conditioned medium induced colony formation (granulocyte colonies with cells ranging from myeloblasts to mature neutrophils and granulocytes) from human and rodent (mouse and rat) bone-marrow cells, although rodent spleen-conditioned medium induced colonies only with rodent bone marrow. Bone marrow from 15 normal subjects yielded a cloning efficiency of 1 colony/ 10^3 cells seeded with an average colony size of 800 cells 14 days after seeding (subjects with bone marrow containing only 1% mature granulocytes exhibited results similar to subjects with 40%). Bone marrow from patients with acute neutrophilic myeloid leukemia had cloning efficiencies 30 times higher (1 colony/30 cells) and larger colonies (4200 cells); 1 patient with eosinophilic acute myeloid leukemia had lower cloning efficiencies (1.5 colonies/2000 cells), and 2 patients with chronic myeloid leukemia had 10- to 100-fold higher cloning efficiencies than normal subjects, and 2 gave no colonies. The cloning efficiency of peripheral blood cells from patients with acute myeloid leukemia was 350 times higher and the colony size 10 times larger than that of normal subjects. Apparently, *in vivo* failure of cell differentiation (as in the acute myeloid leukemic patients) was overcome *in vitro* by the presence of an inducer in the spleen-conditioned medium.

0780 NUTRITION AND EYE CANCER IN CATTLE. (E.) Anderson, D. E. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), L. S. Pope and D. Stephens. *J Nat Cancer Inst* 45(4):697-707, 1970.

In experiments conducted over a 20-yr period, 435 beef cattle were fed winter feed (usually consisting of cottonseed cake and oats or milo) in varying volumes, ranging from 1-2½ pounds/day in order to investigate the association between nutrition and ocular squamous-cell carcinoma. A high level of feeding compared to a low level had an important

effect on increasing lesion manifestation as well as its rate of increase with age. More animals with more advanced lesions were observed at earlier ages in the higher feeding levels than in a medium or low level. At 7-9 yr tumors had developed in 0/5, 0/10 and 2/13 cattle fed at low, medium and high volumes, resp. With the cessation of a feeding trial, the level of susceptibility decreased compared with animals remaining on trial. These decreases were more pronounced in the higher levels than in the low-feeding level. Animals fed at a high level were also heavier and larger and had a lower survival rate than those fed at a low level. The age-adjusted disposal rate for eye cancer was higher with high levels of feeding (14%) than in the low level (1.5%). Animals fed at low levels calved at a later age, and were reproductively inferior to those fed at a high level.

0781 COMPARATIVE STUDY OF RIBONUCLEOTIDE REDUCTASE ACTIVITIES IN NORMAL AND NEOPLASTIC HUMAN TISSUE. (E.) Gordon, H. L. (New England Nucl. Corp., Boston, Mass.), T. J. Bardos and J. L. Ambrus. *Res Commun Chem Path Pharmacol* 1(6):749-756, 1970.

Ribonucleotide reductase activities (method of Gordon and Fiel) were compared in cell extracts from 19 matched human neoplastic and normal tissue pairs. The tissue pairs were grouped according to the anatomical site of origin and histological type, and the neoplasms included glandular and squamous cell carcinomas, melanomas, leiomyosarcoma, rhabdomyosarcoma, and Hodgkin's disease. The ratios of specific activities (nmoles of cytidine diphosphate- $2\text{-}^{14}\text{C}$ reduced/mg protein/hr) of tumor tissue to corresponding normal tissue ranged from 1.1 to 3.2 (the ratio was 13.0 in the case of leiomyosarcoma) in 18 of the tissue pairs studied.

0782 STEROID SYNTHESIS IN A HUMAN VIRILISING ADRENAL CARCINOMA: SOME UNUSUAL FEATURES. (E.) Cameron, E. H. D. (Welsh Natl. Sch. Med., Heath, Cardiff), J. Hammerstein, D. Jones, S. Morris and K. Griffiths. *Acta Endocr* 65(1):133-147, 1970.

Steroids in a human virilising adrenal carcinoma suspected of producing large quantities of dehydroepiandrosterone (DHA) or its sulfate (DHA sulfate) were analyzed following incubation of tumor tissue slices with $1\text{-}^{14}\text{C}$ -acetate, $7\alpha\text{-}^3\text{H}$ -pregnenolone, $4\text{-}^{14}\text{C}$ -progesterone, and $4\text{-}^{14}\text{C}$ -androst-4-ene-3,17-dione by reverse radioisotope dilution techniques. The 11β -, 17α -, 21 -, and 19 -hydroxylase systems in the tumor cells were operating efficiently based on the conversion of $4\text{-}^{14}\text{C}$ -androst-4-ene-3,17-dione to its 11β -hydroxy form (55.7%) and to its 19 -hydroxy form (0.38%) and to 19 -hydroxytestosterone (0.05%), and of $4\text{-}^{14}\text{C}$ -progesterone to cortisol (23.6%) and corticosterone (5.49%). The major metabolite for both $1\text{-}^{14}\text{C}$ -acetate and $7\alpha\text{-}^3\text{H}$ -pregnenolone was DHA suggesting that the tumor secreted DHA rather than DHA sulfate. DHA- 3β -hydroxysteroid dehydrogenase/ $\Delta^5\text{-}^4$ isomerase and DHA- 3β -sulfokinase activities appeared to be low.

- 0783 REGULATION OF ACETYLCHOLINESTERASE IN NEUROBLASTOMA CELLS. (E.) Blume, A. (Nat'l. Heart Lung Inst., Nat'l. Inst. Hlth., Bethesda, Md.), F. Gilbert, S. Wilson, J. Farber, R. Rosenberg and M. Nirenberg. *Proc Nat Acad Sci* 67(2):786-792, 1970.

The activities of acetylcholinesterase (modification of the method of Reed, Goto, and Wang) and catechol-O-methyl transferase (modification of the method of Nikodejevic, Senoh, Daly, and Creveling) in mouse neuroblastoma C-1300 were investigated *in vitro*. The specific activity (nmole product/min/mg) of acetylcholinesterase (AChE) did not change during the periods of rapid cell division, but during the stationary phase of growth it increased 25-fold (7 to 150) while the amount of protein per cell doubled (0.6 to 1.2 ng). The specific activity of catechol-O-methyl transferase did not change significantly during logarithmic or stationary phases of growth. Apparently AChE activity is regulated (inversely related) by the rate of cell division (possibly dependent upon protein synthesis) in neuroblastoma.

- 0784 HISTOCHEMICAL EVALUATION OF ENZYMES IN AMELOBLASTIC TUMORS: ACANTHOMATOUS AND GRANULAR-CELL AMELOBLASTOMA. (E.) Mori, M. (Osaka U. Dent. Sch., Japan). *J Oral Surg* 28(11):825-831, 1970.

Enzyme activity was studied in various odontogenic tumors, specifically acanthomatous and granular-cell ameloblastomas. Tumor material consisted of 106 odontogenic epithelial tumors, including 102 ameloblastomas of which 19 were squamous and squamous metaplastic acanthomas and 22 were follicular tumors. No alkaline phosphatase activity was observed in acanthomatous, granular-cell ameloblastomas or common ameloblastomas. The keratinized region in acanthomatous ameloblastoma and in squamous-cell carcinoma and homologous squamous epithelium were marked by acid phosphatase activity. Excluding the keratinized sites of squamous metaplasia oxidative enzymatic patterns in tumor cells were not altered from normal. Esterase was evident in all neoplastic structures. Granular cells of ameloblastoma were characterized by high activity for acid phosphatase and β -glucuronidase, suggesting substantial lysosomal enzyme activity. Low levels of oxidative enzyme activities in granular cells were also noted. Possibly, degenerative alterations in central ameloblastic foci are responsible for the development of granular cells.

- 0785 EFFECTS OF CANCER UPON HIGH-DENSITY AND OTHER LIPOPROTEINS. (E.) Barclay, M. (Sloan-Kettering Inst. Cancer Res., Walker Lab., Rye, N. Y.), V. P. Skipski, O. Terebus-Kekish, E. M. Greene, R. J. Kaufman and C. C. Stock. *Cancer Res* 30(9):2420-2430, 1970.

The correlation between serum levels of high density lipoproteins (HDL₂ with densities less than 1.21 g/ml) and the probability of developing cancer was examined by quantitating and characterizing serum lipoprotein (quantitative ultracentrifugation and

thin layer chromatography) in normal subjects and patients with cancer. Lipoprotein quantitation (100 ml) in normal women with no family history of cancer and normal women with such histories were similar except that the latter group averaged significantly lower levels of HDL₂ (52 compared to 100) while women with primary operable breast cancer had elevated levels of very low density lipoprotein (VLDL, 103 compared to 12) and decreased levels of HDL₂ (84 compared to 120). Women with advanced operable breast cancer and with different types of cancer had elevated VLDL (103 and 84, resp.) and depressed HDL₂ (51 and 61, resp.). Normal men with family histories of cancer had higher levels of VLDL (197) and lower levels of HDL₂ (26) than men with no such histories (43 and 97, resp.); with various types of cancer also showed elevated VLDL (230) and depressed HDL₂ (23). Children with various types of cancer had lower levels of HDL₂ than normal children (65) but VLDL levels (114 and 122, resp.) were similar.

- 0786 THE GOLGI APPARATUS DURING MITOSIS IN HUMAN MELANOMA CELLS *IN VITRO*. (E.) G. G. (Temple U. Hlth. Sci. Ctr., Philadelphia) and B. R. Brinkley. *Cancer Res* 30(9):2326-2333, 1970.

A line of human melanoma cells (LeCa 19-4) was subjected to electron-microscopy to investigate ultrastructural changes affecting the Golgi apparatus of human melanoma cells *in vitro* during mitosis. In interphase, the Golgi apparatus consisted of numerous interconnected dictyosomes, each of which was composed of 4 cisternae, as a rule. Some of these cisternae had fenestrations along their lateral edges. During prophase, the membranous tubular connections between the dictyosomes were seen to break down; no fenestration of the cisternae was observed. The number and size of cisternae were reduced; the frequency of Golgi elements reached a minimum during anaphase, although some tubular and vesicular membrane elements were present at the lateral edges of single cisternae. These were considered remnants of dictyosomes. Reconstruction of dictyosomes started at the time of nuclear envelope reformation in early telophase. The increase in number of cisternae appeared to be due to apposition of smooth endoplasmic reticulum. The persistence of Golgi elements throughout mitosis was established. The presence of coated vesicles suggested that the cisternae were functional during mitosis. A relationship between Golgi elements and premelanosomes during mitosis could not be demonstrated.

- 0787 THE ZINC CONTENT OF LEUKOCYTES IN CUTANEOUS NEOPLASIA AND NON-MALIGNANT SKIN DISEASES. (Ger.) Zaun, H. (Clin. U. Saarlande Homburg, Germany) and S. Gall. *Arch Klin Exp* 238(3):285-291, 1970.

Zinc content of leukocytes was determined (semiquantitatively) in 42 patients with malignant and premalignant skin tumors and in 70 controls with

er skin conditions. A decrease of zinc content found in all patients with mycosis fungoides, external malignant neoplasia and malignant melanoma with metastases. Patients with precancerous conditions, basal cell carcinoma and acanthoma at an early stage generally exhibited normal leukocytic levels. A non-specific decrease in zinc content was noticed in some cases of nonneoplastic disorders.

8 ELEVATION OF LEUCINE AMINOPEPTIDASE IN DISSEMINATED MALIGNANT DISEASE. (E.) Phillips, R. W. (VA Hosp., Seattle, Wash.) and E. R. Child. *Cancer* 26(5):1006-1012, 1970.

The association of elevated leucine aminopeptidase activity and malignant disease was investigated in patients with malignant conditions. Leucine aminopeptidase levels were measured in serum and urine of all patients by a colorimetric method. The most consistent finding was elevation of 24-hr urine leucine aminopeptidase in patients with invasive and disseminated malignant disease. Urine leucine aminopeptidase was elevated in all 16 cases of disseminated gastrointestinal tract neoplasms (e.g., 180-1430 U/24 hr compared to normal values 50-170 U). Nineteen of 20 cases with disseminated bronchogenic carcinoma had elevated enzyme levels in the urine (e.g., 310-2650 U). All cases of disseminated cancer of the prostate and 9 cases of invasive malignancy of the genitourinary tract showed elevated leucine aminopeptidase levels. Twelve of 15 cases of various anatomic malignancies had elevated urine enzyme levels. Serum levels (versus urine levels) were consistently elevated. Seventeen patients with localized or surgically cured malignancies had normal leucine aminopeptidase values. In only 3 of 10 patients with nonmalignant disease was elevation of leucine aminopeptidase found (excluding cases of liver or pancreatic disease).

9 MICROSPECTROPHOTOMETRIC MEASUREMENTS OF DEOXYRIBONUCLEIC ACID IN HUMAN THYROID CARCINOMAS. (E.) Lindsay, S. (U. California Sch. of Med., San Francisco). *Surg Gynec Obstet* 131(5):891-913, 1970.

Microspectrophotometric methods were used to compare the nuclear DNA contents of thyroid carcinomas with those of thyroid adenomas, diffuse toxic goiters, and normal thyroids. Feulgen-stained tissue sections were prepared from tissue taken from human patients and used for microspectrophotometric histograms for analysis of DNA content. Histograms of DNA values for papillary thyroid carcinomas were significantly lower than for other tumors, primary carcinomas for DNA contents appearing at 2c or less (arbitrary units) compared with normal thyroid values tending to 4c. DNA content values for papillary carcinoma were significantly lower than values for follicular carcinomas. Papillary carcinomas showed a wide degree of aneuploidy, with hypodiploid modes evident in 3 of the 6 instances of this lesion. Microspectrophotometric measurement of DNA content may

be useful in discriminating follicular variants of papillary carcinoma from true follicular carcinoma.

0790 TRANSFER RNA SPECIES IN NORMAL AND LEUKEMIC HUMAN LYMPHOBLASTS. (E.) Gallo, R. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and S. Petska. *J Molec Biol* 52(2):195-219, 1970.

A study was undertaken to identify the transfer RNA's for every amino acid in human tissues. Isoaccepting species of transfer RNA of normal and leukemic human lymphoblasts were fractionated by reverse-phase partition column chromatography, and the aminoacyl-transfer RNA profile of normal and leukemic lymphoblasts were compared by co-chromatography using ^3H and ^{14}C for labels, and the acid-activating enzyme. Differences between the aminoacyl-transfer RNA profiles of normal and leukemic cells were determined by labeled amino acid reversal and acylation with heterologous enzymes. At least 56 species of transfer RNA were fractionated from normal and leukemic lymphoblasts, and in the case of most amino acids, aminoacyl-transfer RNA profiles for both normal and leukemic cells were similar if not identical. Small but significant differences in profiles of normal and leukemic cells were detected for the transfer RNA of leucine, serine, threonine and proline. Leucine transfer RNA of leukemic lymphoblasts showed a greater amount of ^3H disintegrated/min than did leucine transfer RNA of normal cells (10 and 5% disintegration for leukemic and normal cells, resp.). Similar differences were found for normal and leukemic serine. Leukemic threonine transfer RNA eluted at a higher salt concentration than normal threonine transfer RNA. More pronounced differences between normal and leukemic transfer RNA were exhibited by tyrosine and glutamine transfer RNA, the former showing an extra isoaccepting species found only in normal lymphoblast preparations.

0791 CORRELATION OF TRANSFER RNA METHYLASE ACTIVITY WITH GROWTH AND DIFFERENTIATION IN NORMAL AND NEOPLASTIC TISSUES. (E.) Riddick, D. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and R. C. Gallo. *Cancer Res* 30(10):2484-2492, 1970.

Nine biological systems, consisting of cultures of human and murine tissues, both normal and neoplastic, were studied to determine whether there is any correlation between RNA methylase activity and cell growth and differentiation, or neoplasia. RNA methylase activity was identical in blast cells grown in long-term tissue culture and originally derived from the peripheral blood of normal patients and from patients with various hematological cancers (RNA methylase activity values of 70 and 43 cpm/ μg protein/hr for cells harvested in logarithmic and stationary growth phases, resp., for cells of the P-3 strain). Human lymphocytes, obtained from the peripheral blood of normal donors, which were not propagated in tissue culture and not "in cycle," had low activity (19.9 cpm/ μg protein/hr). However,

after stimulation with the mitogen, phytohemagglutinin, a 3-fold induction occurred, resulting in levels comparable to those observed in the tissue culture lines. Low and similar tRNA methylase activity was observed in bone marrow from normal individuals and patients with chronic myelocytic leukemia when marrow differentials revealed equivalent levels of cellular differentiation (around 2.5 cpm/ μ g protein/hr). However, the activity was 3-fold higher in leukemic marrows when the percentage of primitive cells (myeloblasts) was greater than 40%. Although activity was higher in spleen from leukemic AKR mice compared to normal AKR mice (14 cpm/ μ g protein/hr and 140 cpm/ μ g protein/hr, resp., for normal and leukemic mice), activity was not directly correlated with growth rate since the levels were identical in different groups of AKR leukemic cells over a 10-fold difference in growth rate. The activity was similar in two histologically similar spontaneous murine mammary tumors differing in growth rate (9.2 and 7.5 cpm/ μ g protein/hr for the fast and slow-growth lines, resp.). The data suggest that increased tRNA methylase activity, possibly including qualitatively different enzymes, is characteristic of immature normal cells as well as neoplastic cells. Furthermore, once fully expressed, tRNA methylases of neoplastic cells apparently do not increase further with an increase in growth rate. The percentage of cells in cycle seems to determine the increase in tRNA methylase activity.

- 0792 RNA DEPENDENT DNA POLYMERASE OF HUMAN ACUTE LEUKAEMIC CELLS. (E.) Gallo, R. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), S. S. Yang, and R. C. Ting. *Nature* 228(5275): 927-929, 1970.

Nucleic acid-free preparations from lymphocytes of peripheral blood cultures from 3 patients with acute lymphoblastic leukemia and from phytohemagglutinin-stimulated lymphocyte cultures from 48 normal subjects were prepared. No RNA dependent DNA polymerase activity was detected in any of the preparations from normal lymphoblasts. Lymphoblasts from patients with acute lymphoblastic leukemia demonstrated considerable DNA polymerase activity which was dependent on the presence of all 4-deoxynucleoside triphosphates, Mg^{+2} , and rat liver RNA; 2 μ g/ml of ribonuclease inhibited the reaction by 90%. 3H -Thymidine triphosphate was incorporated into an acid-precipitable product which was completely hydrolyzed by deoxyribonuclease. The RNA dependent DNA polymerase was completely inhibited by 460 μ g/ml of N-demethylrifampicin. The finding of an RNA dependent DNA polymerase in acute lymphoblastic leukemic lymphoblasts and the absence of this activity from normal lymphoblasts is consistent with a viral etiology.

- 0793 AUTORADIOGRAPHIC STUDIES OF THE PROTEIN SYNTHESIS IN THE MAMMARY CANCER TISSUE OF MICE. (Rus.) Gabuniya, U. A. (Georgian SSR Acad. Sci., Tbilisi, USSR) and N. N. Shiukashvili. *Vop Onkol* 16(7):43-46, 1970.

The rate of protein synthesis and metabolism in mammary gland tumor tissues was studied by autoradiography in C3H tumor-bearing mice (9-10 months old) using S^{35} methionine (0.5 μ C/g body wt, i.v.). The animals were sacrificed 15, 30 min, 1, 4, 28, 96 and 144 hr after label administration. The rate of tumor parenchymal methionine incorporation reached a maximum 60 min after tracer injection, reflecting a stage of maximal protein synthesis. After the radioactivity decreased to 50% of its maximum after 80 hr and to trace levels at 144 hr after beginning of the experiment. This decrease was possibly associated with label dilutions due to cell division processes. A redistribution of label from the tumor tissue was noticed during the experiment. 90% of the label was contained within the tumor cells and 10% was distributed in the intercellular spaces during the first minutes, but this latter activity became equal to the intracellular level at the 5th hr of experimentation, increasing thereafter through the 10th hr, when only traces of label were detectable within the cell. The intracellular to extracellular substance ratio was 56/44 in stroma-free tumor tissue samples. These data seemed to suggest that the major part of tumor cell-synthesized protein was eliminated into the intercellular spaces and that only 10% of this protein was used for growth and multiplication of the tumor cells.

- 0794 AN ABNORMAL PHOSPHOGLUCOMUTASE COMPONENT IN CHRONIC LYMPHATIC LEUKAEMIA. (E.)

L. U. (Inst. Med. Microbiol., U. Aarhus, Denmark) and K. B. Jensen. *Scand J Haemat* 7(4):243-246, 1970.

Lymphocyte phosphoglucomutase isozymes were separated by electrophoresis in 13 patients (12 males and 1 female) with chronic lymphatic leukemia and more than 90% lymphocytes in the peripheral blood. In 10 male patients, 1 or 2 extra phosphoglucomutase components were discovered between the phosphoglucomutase₂ and the phosphoglucomutase₃ series of isozymes. In 3 of the patients, the abnormal isozyme found in the peripheral leucocytes was also found in the bone marrow. However, completely normal isozyme patterns were found in lymph node biopsies.

- 0795 RECURRING DIGITAL FIBROUS TUMOR OF THE FINGER: AN ELECTRON MICROSCOPIC AND VIROLOGICAL STUDY. (E.) Burry, A. F. (Roy. Brompton Hosp., Australia), J. F. R. Kerr and J. Pope. *Pathology* 2(4):287-291, 1970.

The histological appearance of a digital fibrous tumor was examined under the electron microscope. The tumor arose on the fourth finger of a 3 month old child; upon removal another similar tumor developed at the same site. Microscopically, the tumor presented the appearance of a digital fibrous tumor of the type described by Reye. The large cytoplasmic inclusions that constitute the distinctive histological feature of Reye's lesion comprised compact masses of granules and filaments.

thout a limiting membrane in the tumor examined. They closely resembled structures that have been shown to develop in the cytoplasm of cells infected with various species of viruses and that have been interpreted as virus assembly sites. However, no viral particles could be identified in the tumor and attempts to isolate viruses were unsuccessful. Crystalline bodies were frequently found in the vicinity of the granular inclusions, but their significance was not clear. The tumor was established in tissue culture, and bodies bearing a resemblance to the cytoplasmic inclusions were found in the cultures.

96 FAMILIAL LEUKEMIA: A REPORT OF 4 CASES OF ACUTE LEUKEMIA IN 4 CONSECUTIVE GENERATIONS. (E.) Ferguson, S. W. (U. Oklahoma Med. Cn., Oklahoma City) and T. N. Lynn. *Southern Med J* (11):1337-1340, 1970.

The occurrence of 4 cases of acute lymphocytic leukemia in an Oklahoma farming family was studied. The earliest case of leukemia occurred in 1942, and the most recent in 1966. The second occurred in 1946 and was a daughter of No. 1, the mother of No. 3 and the paternal grandmother of No. 4. Onset was at an earlier age in each generation, i.e., for No. 1, 41 for No. 2, 35 for No. 3, and 14 for No. 4. Each was the second eldest child in his birthship, and all were female except No. 3. Malignant tumors occurred in 6 family members, and a blood disorder of undetermined nature in another. Cytogenetic studies in 14 close relatives revealed eight hyperdiploidy in 3 persons, one of whom also showed increased chromosome breakage. The picture of familial leukemia presented by these 4 cases is apparently consistent with the possibility of vertical transmission of an infectious viral agent in familial aggregations of leukemia.

97 CHROMOSOME ABNORMALITY AND ITS SIGNIFICANCE IN HUMAN MULTIPLE MYELOMA. (E.) Itani, S. (Kyoto Hosp., Japan), T. Hoshino, S. Kawasaki and Nakayama. *Acta Haem Jap* 33(1):54-66, 1970.

Chromosome analysis (modified method of Tjio and Chang for bone marrow cells and a modified method of Moorhead for cultured peripheral blood cells) was performed on 8 patients with myeloma and on 1 patient with primary macroglobulinemia. The modal chromosome number was 46 in all cases, and in only 2 cases a small tetraploid mode was observed. Karyograms in 2 cases showed only minor aberrations, but the remaining cases demonstrated independent abnormal cell lines characterized by MG-like, Bq-, aberrant-C, and Dq-marker chromosomes (one patient with myeloma of no-anomaly type had many marker chromosomes). Associations observed between Dq+ and MG-like, Dq+ and aberrant-C, and Bq- and aberrant-C suggest that the abnormal cell lines generate new sub-clones with new marker chromosomes. Such chromosomal abnormalities may be important in the development of the abnormal cell line of the lymphoreticular system in patients with myeloma.

0798 CYTOGENETIC STUDIES IN ACUTE MYELOCYTIC LEUKEMIA WITH SPECIAL EMPHASIS ON THE OCCURRENCE OF Ph¹ CHROMOSOME. (E.) Whang-Peng, J. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), E. S. Henderson, T. Knutsen, E. J. Freireich and J. J. Gart. *Blood* 36(4):448-457, 1970.

When bone marrow and peripheral blood of 103 patients with acute myelogenous leukemia were subjected to cytogenetic studies, 73 patients were found to have a normal karyotype and 30 patients were found to be aneuploid. No unique chromosomal abnormalities were found in patients with aneuploidy except for a significantly higher incidence of G group involvement. Four cases had a history of radiation exposure; 3 of these 4 patients had a normal karyotype and one had one Ph¹ chromosome in her bone marrow cells. Another patient with no history of radiation also had one Ph¹ chromosome in his marrow cells. Reclassification of acute myelogenous leukemia patients with Ph¹ chromosomes as a rare entity of blast crisis in chronic myelogenous leukemia rather than as acute myelogenous leukemia is proposed. Two patients exhibited the 45 chromosome syndrome before the diagnosis of acute myelogenous leukemia was made. The normal and aneuploid groups had about the same median survival time and same median date from diagnosis to chromosome study; however, although 7 patients in the normal group karyotype lived for more than 26 months from the date of diagnosis, none of the aneuploid patients survived for longer than 26 months.

0799 MYELOPROLIFERATIVE DISEASE IN A CHILD WITH MONOSOMIA OF A C GROUP CHROMOSOME. (E.) Polak, J. (Fac. Med. Hradec Kralove, Czechoslovakia) and J. Zizka. *Acta Paediat Scand* 59(5):591-595, 1970.

A 4-yr-old girl presented with a myeloid leukemic reaction with nucleated red cells and atypical lymphocytes in the peripheral blood, together with hepatosplenomegaly. The disease was benign at its first stages and did not influence the normal growth and development of the patient up to the age of 4 yr. Then an acute deterioration appeared with a picture of acute erythremia and the child died with signs of panmyelophthisis. The cytogenetic examination showed monosomia of a C group chromosome in mitoses of bone marrow cells at the age of 2 years and, in addition, a ring chromosome in this group in the terminal phase. Polycythemia vera may have led to myeloproliferative disease in this case; however, neither erythrocytosis nor thrombocytosis were observed in any phase of the disease.

0800 CHROMOSOME STUDIES IN HEMATOLOGICAL DISORDERS: III. CHROMOSOME FINDINGS IN "PRE-LEUKEMIA" AND RELATED DISEASES. (E.) Sakurai, M. (Fac. Med. Kyoto U., Japan). *Acta Haemat Jap* 33(1):127-136, 1970.

Chromosomes of 18 patients with preleukemia and other related hematological disorders (leukocytosis, poly-

cythemia vera, aplastic anemia, myelofibrosis, and purpura) were analyzed (bone marrow method of Sakurai and/or peripheral blood method of Moorhead). Abnormalities were observed in 3 patients, all of whom were suffering from aplastic anemia. An XO/XY mosaicism was detected in the marrow of 2 patients and a large Y chromosome was seen in both marrow and peripheral blood cultures of the third patient, while the 3 patients who were clinically preleukemic (and subsequently developed leukemia) exhibited no chromosomal abnormalities.

- 0801 DIFFERENCES IN Rh TYPE BETWEEN AGE GROUPS OF LEUKEMIA PATIENTS. (E.) De George, F. V. (Dept. Med. Genet., U. Wisconsin, Madison). *Nature* 228(5267):168-169, 1970.

Blood type and Rh factor were determined in 374 patients with acute or chronic leukemia to investigate the correlation between blood type and Rh factor and age, sex and chronicity of the patient. No significant differences were found in the distribution of the ABO blood groups among categories of age or chronicity; however, patients with acute or chronic leukemia in the age group 0-4 yr and 51-90 yr had higher frequencies of Rh negative factors than patients between 5-50 yr (frequencies of 22.06, 25.93, and 11.30%, resp., for acute patients and 33.33, 21.11, and 10.53%, resp., for chronic patients). The same age dependent heterogeneity in Rh frequencies was observed when data were analyzed separately for men and women; however, the frequency difference among women of different ages is not statistically significant. It may be important that the 2 age groups in which Rh negativity was unusually high among patients, 0-4 and 51-90 yr, are the age groups with the highest incidence of leukemia.

- 0802 LYMPHOSARCOMA IN THE RABBIT: GENETICS AND PATHOLOGY. (E.) Fox, R. R. (Jackson Lab., Bar Harbor, Me.), H. Meier, D. D. Crary, D. D. Myers, R. F. Norberg and C. W. Laird. *J Nat Cancer Inst* 45(4):719-729, 1970.

Twenty-nine rabbits with lymphosarcoma were subjected to pathological and genetic studies with the result that lymphosarcoma appeared to be inherited as an autosomal recessive trait, the gene involved being designated *ls*. Findings were compatible with a hypothesis of genetic susceptibility to lymphosarcoma, as well as with a hypothesis of vertical transmission of a virus. Mean age at onset of the disease was 8.4 months for females and 7.8 months for males; affected rabbits usually died between the ages of 5 and 13 months. The neoplastic involvement of lymphoreticular organs and kidneys corresponded to a pattern observed in lymphosarcoma of visceral lymphosarcomatosis of cats, which has been proved unequivocally to be caused by feline leukemia virus. This similarity between rabbit and cat lymphosarcomas involved both the sites of onset and the distribution of the neoplastic lesions and the hematologic findings of a predominantly aleukemic picture. However, in rabbit lymphosarcomas, a relative increase in circulating lymphoid cells was

frequently found, including lymphocytes of both mature and atypical forms.

- 0803 FAMILIAL PHEOCHROMOCYTOMA, MEDULLARY THYROID CARCINOMA, AND PARATHYROID ADENOMA. (E.) Paloyan, E. (U. Chicago Pritzker Sch. Med. Ill.), A. Scanu, F. H. Straus, J. R. Pickleman, D. Paloyan. *JAMA* 214(8):1443-1447, 1970.

A case is presented in which a female patient, served over a period of 15 yr, developed a malignant bilateral pheochromocytoma metastasizing to the falciform ligament and to the liver, an infiltrative medullary carcinoma of the thyroid, and 3 parathyroid adenomas, 1 having an unusual vascular distribution. The patient had a sister and a brother of whom had developed bilateral pheochromocytoma. High concentrations of calcitonin in the medullary thyroid cancer (250-750 times normal calcitonin activity) was observed. Morphologically, the medullary thyroid tumor and the metastases from the pheochromocytoma were similar. In view of the recent discovery of a calcitonin-like substance in the adrenal medulla and the morphological similarity between the calcitonin-producing cancer and the pheochromocytoma's metastases, it may be that the syndrome shown by this patient represents a defect in the neuroectodermal cell system.

- 0804 CHROMOSOMAL CHARACTERISTICS OF NEUROBLASTOMAS IN CHILDREN. (E.) Mark, J. (Path., U. Lund, Sweden). *Acta Cytol* 14(8):511-514, 1970.

Chromosomes were studied in preparations from neurogenic tumors in children, the tumors examined including 3 primary and 1 metastatic medulloblastomas, 1 optical glioma and 2 primary and 1 metastatic neuroblastomas. Among the primary tumors about 75 per cent had their mode in the diploid group and in the polyploid group the tetraploids were more frequent than the triploids. The same pattern of modality occurred in primary malignant gliomas of the adult, whereas in other solid neoplasms in adults the diploids were found in a considerably lower frequency and the triploids outnumbered the tetraploids. The gliomas in adults differed from the neurogenic tumors in children by the absence of tumors with a normal, diploid stemline and few tumors with a pseudodiploid mode. The metastatic tumors also showed a higher frequency of stemline in the diploid region in comparison with corresponding lesions in the adult, but the progression trends were similar in both materials. In both primary and secondary neurogenic tumors in children structural aberrations were somewhat more frequent than in correspondent neoplastic conditions in the adult. A statistical analysis of the chromosomal representation in the tumor stemlines of the children revealed a non-random pattern; though less pronounced, the characteristics of this pattern were similar to those observed in advanced tumors in the adult. Apparently, in a given tumor group, the chromosomal characteristics are significantly related with the tissue of origin and the length of growth period.

05 CHROMOSOMAL ANALYSIS OF A HUMAN RETINOBLASTOMA. (E.) Mark, J. (Inst. Path., U. Lund, Sweden). *Acta Ophthalmol* 48(1):124-135, 1970.

errations in the chromosomes of cells taken from sporadic human retinoblastoma were studied in preparations of the tumor tissue. The karyotype of the retinoblastoma was characterized from the analysis of 51 metaphases; hyperdiploid stem-side-lines with characteristic marker chromosomes, a restricted spread around the stemline number, and the polyploid mitoses were observed. The findings differed completely from the inconsistent pattern reported for another sporadic retinoblastoma, investigated exclusively after explantation *in vitro*. This previously described retinoblastoma, a deletion affecting one of the long acrocentrics (D chromosome) was found both in normal and tumor cells. This deletion was not seen in the present case. A pattern of early and gradual substitution of tumor cells by stroma cells was observed from *in vitro* examination of this retinoblastoma. No obvious similarities were found between the chromosomes of the retinoblastoma and those of medulloblastomas or neuroblastomas.

06 Dq-, Dr AND RETINOBLASTOMA. (E.) Taylor, A. I. (Guy's Hosp. Med. Sch., London, England). *Humangenetik* 10(3):209-217, 1970.

Information on 30 cases of patients with Dq- or Dr chromosomes, 28 from the literature and 2 new reports, was assembled to survey the symptoms associated with these chromosomal abnormalities; prominent symptom associated with the condition was retinoblastoma. Both the new cases involved male infants of normal parents who presented the chromosome; 1 patient showed marked abnormalities including mental and growth retardation, while the other showed less severe abnormalities including retardation and bilateral retinoblastoma. Six of 11 Dq- patients in the case reviews had retinoblastoma, while none of the 15 Dr cases had retinoblastoma. All retinoblastoma patients showed mental and physical retardation, and most had minor somatic anomalies. The gene associated with retinoblastoma may be positioned on the proximal D arm near the centromere, a hypothesis which would explain the absence of retinoblastoma in the chromosome cases which have fairly long ring chromosomes with small long arm deletions.

07 DESULFURASE ACTIVITY AND CHROMOSOME ANALYSIS OF CULTURED RAT HEPATOMA CELLS. (E.) Jackson, J. F. (Sch. Med. U. Mississippi, Jackson) and P. A. Morse. *Europ J Clin Biol Res* 15(8):906-910, 1970.

Cysteine desulfurase and β -mercaptopyruvate desulfurase activities (modified tetrazolium method of Barrett) and chromosome modalities were determined in cultured rat hepatoma cells (Novikoff N1 and N2 and Reuber H4A and H4C). The modal chromosome number was 39 for both strains of Novikoff tumor, 55 for Reuber H4A, and 56 for Reuber H4C compared to

the normal 42 for the rat. The chromosomally heteroploid Reuber hepatomas were generally low in both cysteine and β -mercaptopyruvate desulfurase activities (85-92% of the total cells showing only faint staining), while the near diploid Novikoff hepatomas exhibited greater desulfurase activity (56-67% of the total cells showing readily detectable or heavy staining). An accumulation of β -mercaptopyruvate in tumors deficient in desulfurase activity may contribute to the development of polyploidy.

0808 FAMILIAL OVARIAN CARCINOMA. (E.) Li, F. P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), A. H. Rapoport, J. F. Fraumeni, Jr. and R. D. Jensen. *JAMA* 214(8):1559-1561, 1970.

In a white family of Anglo-Saxon origin, ovarian carcinoma occurred in 4 sisters and in 6 of their relatives over 3 generations; the tumors were primarily papillary adenocarcinomas, a histological type reported in another case of familial ovarian cancer. In this family examined, ovarian carcinoma appeared to be transmitted through males as well as through females, and the pattern of involvement suggested the activity of a dominant gene with variable penetrance or possibly a polygenic mechanism. Familial occurrence of ovarian carcinoma may result from genetic susceptibility of ovarian tissue to hormonal or other carcinogenic influences. Alternatively, the genetic defect may induce hormonal imbalance which is potentially carcinogenic.

0809 CHROMOSOME CHANGES IN INVASIVE CARCINOMAS OF THE UTERINE CERVIX. (E.) Auersperg, N. (Cancer Res. Ctr., U. British Columbia, Vancouver, Canada) and T. Wakonig-Vaartaja. *Acta Cytol* 14(8):495-501, 1970.

Chromosome preparations from 8 cases of invasive squamous cell carcinoma of the cervix were subjected to karyotype analyses to investigate chromosome changes associated with cervical carcinogenesis. The chromosome distribution in the 8 carcinomas varied considerably between individual cases, but there was a reduced proportion of chromosomes in group B in all tumors, and in groups A, D and G in most tumors. The proportion of chromosomes in groups C and E was usually increased. Recurring markers included ring chromosomes in four of the carcinomas and an Api chromosome in an early invasive lesion. Apparently, there is a correlation between the varying stages of the disease and the nonrandom chromosomal changes which occur in cervical carcinogenesis.

0810 SEX CHROMATIN IN ENDOMETRIAL CANCER. (E.) Siracky, J. (Oncol. Inst. Bratislava, Czechoslovakia), B. Belohorsky and E. Siracka. *Neoplasma* 17(4):399-403, 1970.

The incidence and characteristics of sex chromatin material in patients with endometrial cancer was investigated. Primary tumor sections from 119 patients with endometrial cancer were examined; some

patients had been treated with surgery, and some with radiation therapy. Tumor tissue was sex chromatin-negative in 22.7% of cases, positive in 77.3% (where "sex chromatin-negative" cells contained less than 10% sex chromatin bodies in their nuclei). Most sex chromatin-negative cases (70%) appeared as poorly differentiated cancers. The total 5-yr survival rate after treatment (surgery and/or radiation) was higher in the group of sex-chromatin positive cases (sex chromatin positive cases 54%, sex chromatin negative cases 40%). In the group of sex chromatin negative cases which were given radiation therapy the 5-yr survival was 26% only, while in the group of sex chromatin positive cases having radiation therapy 5-yr survival amounted to 58%. A relationship between the biological properties of the tumor and its cytogenetic characteristics may be indicated by the observed difference in survival rates.

- 0811 SPONTANEOUS KIDNEY TUMORS IN A SUBSTRAIN OF R111/Dm/Se MICE. (It.) Ribacchi, R. (Dept. Res. Cancer, U. Perugia, Italy). *Lav. Anat. Pat. Perugia* 30(2):73-88, 1970.

The occurrence of 7 multiple nodular transplantable spontaneous kidney tumors of tubular epithelial origin was observed through 50 generations (a total of 5300 animals) of 3 substrains (A, B, C) of R111/Dm/Se inbred mice. The mice were maintained on a normal pellet diet. The first kidney tumor occurred in a male of the 40th inbred generation of the A substrain and 6 kidney tumors occurred in 5 males and 1 female (bearing a minor mammary tumor) in 3 consecutive generations of the B substrain (1 in the 43rd, 2 in the 44th and 3 in the 45th, the latter occurring in descendants of the brood in which the first tumor occurred) at 548-599 days of age. No mouse of the C substrain developed kidney tumors. The incidence of kidney tumors throughout the 3 mentioned generations in the B substrain was 50% (5 out of 10 animals) in males and 10% (1 out of 10) in females, while the other 90% of females developed mammary tumors at an average age of 455 days. The incidence of mammary gland tumors in 3 groups of generations of the B substrain (females of the 36-42nd, 43-45th and 46-49th generations) was 44% (12 out of 27), resp., and occurred at the average age of 434, 455 and 332 days, resp., indicating that a weakening of the MTV potency occurred in the generations preceding the appearance of the kidney tumors. The C breeders exhibited the highest incidence of mammary tumors (94% occurring at an average age of 266 days through the 36-49th generations), while the B breeders had the lowest incidence (69% occurring at the average age of 402 days). The development of kidney tumors seemed to be determined by chromosomal and/or extrachromosomal factors interfering with the transmission of the potency of the MTV.

- 0812 PROLIFERATION AND DIFFERENTIATION OF PIGMENT CELLS *IN VITRO*. (E.) Hu, F. (Oregon Reg. Primate Res. Ctr, Beaverton) and Y. Kitano. *J Invest Derm* 55(6):444-451, 1970.

The relation between proliferation and melanin maturation (quantitated by a modification of the method of Foster, Tremblay, and Stamas) was studied in layer cultures of mouse pigment cells. A pigmented cell (440B) proliferated to form a colony of pigmented cells (not all the colonies formed uniformly pigmented), and a nonpigmented cell formed a nonpigmented colony. The melanin content (measured by optical density) of a cell did not increase until the proliferation had decreased (2.66 at 6 days, 3.37 at 9 days, 3.37 at 12 days, and 5.40 at 15 days). Light did not significantly alter the cell count (363.8×10^4 compared to 371.7×10^4 cells at 15 days) but did lower the melanin content (2.24 compared to 3.37 at 12 days), and culturing on the edge of the dish increased the melanin content (6.08 compared to 4.08 at 15 days) without affecting cell count (280.8-324.9 cells). Radioisotope incorporation studies (^{14}C -tyrosine and ^3H -thymidine) indicated that the values of thymidine incorporation (protein synthesis) were inversely related to thymidine incorporation (melanin synthesis).

- 0813 PROLIFERATIVE ACTIVITY AND CYTOCHEMICAL PROPERTIES OF NUCLEAR CHROMATIN RELATIVE TO LOCAL CELL DENSITY OF EPITHELIAL CELLS. (E.) Terberg, A. (Karolinska Inst., Stockholm, Sweden) and G. Auer. *Exp Cell Res* 62(1):262-270, 1970.

Proliferative activity (DNA synthesis and cytochemical properties) and cytochemical properties (capacity to bind acridine orange and resistance to heat denaturation) of nuclear chromatin were studied in relation to the function of local cell density in primary monolayer cultures of mouse kidney epithelial cells. Confluent cell layers were found to occupy a constant surface area in the culture in inverse proportion to the cell density. As cell densities (cell number per unit area) increased from 10,000 to 50,000 the percentage of ^3H -thymidine-labeled cells dropped rapidly (from 5% to 1%); from 50,000 to 100,000 it decreased slowly (to 1%), and above 150,000 no further incorporation was detected, although small "non-proliferative" areas with cell densities of 250,000 were seen that might have resulted from cellular crowding or epithelial sheet retraction. Cells in these non-proliferative areas bound 40% more acridine orange than cells in the lower density areas, and the chromatin was more resistant to heat denaturation. At low cell densities (below 10,000) cell nuclei contained postmitotic, intermediate levels of DNA, but at higher densities the cell nuclei contained only postmitotic levels of DNA, indicating that the inhibition of cell proliferation resulted from the failure of the initiation of DNA synthesis in the G_1 phase.

- 0814 THE INFLUENCE OF NORMAL CELLS ON THE PROLIFERATION OF TUMOR CELLS IN CULTURE. Weiss, R. A. (Dept. Anat., Embryol., U. College London, England). *Exp Cell Res* 63(1):1-18, 1970.

The effect of population density of normal cells on the proliferation of tumor cells (chick, mouse, rat, quail, and embryo cells) on the proliferation of Rous,

sarcoma 180 cells was studied. Rous sarcoma virus (RSV)-transformed chick embryo cells proliferated without density dependence on the sparse proliferating ($375-500$ cells/mm²) and on the dense static (1500 cells/mm²) sheets of normal chick embryo, and the transformation of normal cells was inhibited at high densities. On dense sheets of chick embryo cells fully-transformed cells were inhibited but freshly infected cells were markedly stimulated (21-27 Rous foci compared to 249-276 with fully-transformed cells). RSV-transformed cells originating from chick, rat, or hamster embryos were not inhibited by dense sheets of normal mouse or chick cells; polyoma and S180 cells were inhibited on dense sheets of mouse or rat cells but not by chicken, goose, or chick cells. Both mouse and chick cells exerted a feeder effect on tumor cell growth on monolayer and suspension. Different types of tumor cells respond differently to the inhibitory influence of crowded normal cells, and avian and mammalian embryo cells exhibit different capacities to inhibit tumor cells.

5 THE SYNERGIC EFFECT OF ESTROGENS AND POLYETHYLENE STRIP INSERTIONS ON THE UTERINE TUBES OF GUINEA PIGS. (Fr.) Raitcheff, I. (Higher Inst. Med., Sofia, Bulgaria). *Bull Cancer* 67(1):121-132, 1970.

The morphological alterations of guinea pig uterus were studied after local application of vitestrol, a Bulgarian estrogenic preparation, after castration (15-20 days before treatment) and after ligation of the uterine tubes by means of polyethylene strips. Fifty-eight female guinea pigs were castrated and divided into 4 groups: one group consisted of 12 animals having the top ends of both uterine tubes ligated with 2 mm wide polyethylene strips and treated with 15,000 I.U. of vitestrol weekly for 2½-6 months; the 2nd group consisted of 22 animals with unilateral (right tube) ligation, otherwise treated identically for 3-week months with 1 animal treated for 9 months; the 3rd (10 animals) and 4th (14 animals) groups were controls subjected to bilateral and unilateral ligation and were given no vitestrol. Nodular hyperplastic proliferations of the connective tissue were noticed on the top segments of uterine tubes in 12 animals of the 1st and 17 animals of the 2nd group (receiving 105,000-555,000 I.U. of vitestrol). Neoplastic proliferation (fibroma) was observed close to the ligation sites in 5 animals of the 1st and 8 animals of the 2nd group. Irregular hyperplastic proliferation where the collagenous fibers lost their usual orientation and diffuse leiomyomatous structures were noticed in 1 animal of the 1st group after 2½ months of treatment. Hyperproliferation of the collagenous connective tissue of the ligated tube segment was noticed in 1 animal of the 2 control groups 10 months after unilateral application of the strip. No neoplastic proliferations occurred in the control animals.

6 THE TUMOR GROWTH PROMOTING EFFECT OF ε-N-TRIMETHYL LYSINE. (E.) Szende, B. (Semmelweis Med. U., Budapest, Hungary), E. Tyihak, L. Szepes and K. Lapis. *Neoplasma* 17(4):433-434, 1970.

Tumor-bearing female mice were given i.p. or s.c. doses of 5-10 mg/kg body wt of pure DL-ε-N-trimethyl lysine, and the growth-promoting effect of this compound on Ehrlich subcutaneous carcinoma and NK/Ly ascites lymphoma was observed; ε-N-methylated lysine components have previously been ascertained to be the basic protein fraction of the cells of these tumors. Tumor growth was promoted by as much as 50-60% in the 2 tumor types following treatment with the compound in doses of 5 and 10 mg. In the case of the ascites lymphoma, an i.p. 10 mg dose produced an elevated DNA level in tumor cells after 6 hr, and, after 24 hr, an elevation of the whole protein-level. Larger amounts of ε-N-methylated lysine were found in the arginine-rich histone and in the acid-insoluble protein fraction of treated tumor cells.

0817 THE EFFECT OF RNA, ISOLATED FROM BONES AND EMBRYONAL TISSUES, ON THE GROWTH OF M-1 SARCOMA. (Rus.) Pankov, E. Ya. (Serbsky Inst. Prosthet. Orthop. Traumat., Kharkov, USSR) and N. V. Dedukh. *Biull Eksp Biol Med* 70(9):72-75, 1970.

The effect of bone and embryonal tissue RNA on tumor growth was studied in 128 rats (80-90 g). Control animals were inoculated s.c. with a suspension of M-1 sarcoma cells (100% transplantability). RNA extracted from rat bones was added to tumor cell incubation media containing 800,000 cells at a ratio of 48 and 50 µg/ml. Embryonal RNA (obtained after the removal of internal organs, head and skin) was added in amounts of 50, 500 and 1000 µg/ml of nutrient media containing 800,000 cells. RNase-treated RNA and trypsin-treated RNA were added to other samples of sarcoma cell cultures. All animals were sacrificed 20 days after cell culture inoculation. Bone RNA decreased the tumor transplantability by 38-59%, but ribonuclease-treated RNA exhibited no inhibitory effect on tumor development; trypsin had no effect on the RNA-determined tumor growth inhibition. RNA from embryonal tissue produced no tumor growth inhibition effects.

0818 STIMULATION OF MITOTIC ACTIVITY IN RAT BONE MARROW AND THYMUS BY EXOGENOUS ADENOSINE 3'5'-MONOPHOSPHATE (CYCLIC AMP). (E.) Rixon, R. H. (Div. Biol., Natl. Res. Council Canada, Ottawa), J. F. Whitfield and J. P. MacManus. *Exp Cell Res* 63(1):110-116, 1970.

Mitotic activity in rat bone marrow and thymus cells was determined in the presence and absence of Colcemid (0.2 mg/100 g, i.p.) after i.p. administration of adenosine 3',5'-cyclic monophosphate (cyclic AMP), dibutyryl adenosine 3',5'-cyclic monophosphate, or AMP. The proportion of cell population which reached Colcemid-metaphase in 6 hr was increased from 14% to 18.5% by cyclic AMP (5 mg/kg, i.p.), from 5.4% to 8.0% by the dibutyryl derivative of cyclic AMP, and was not affected by AMP (2-15 mg/kg, i.p.). The stimulatory activity of these nucleotides was limited to doses between 4 and 6 mg/kg (when 15 mg/kg was tested, a 4 hr delay was observed while the mitogenically ineffective level of circulating nucleotide decreased to a stimulatory

level). The stimulatory activity of dibutyryl-cyclic AMP was also evident in the absence of Colcemid (the mitotic index increased from 1.14% to 2.17% in bone marrow cells and from 0.79% to 1.53% in thymus cells). The stimulatory ability of cyclic AMP supports the hypothesis that this cyclic nucleotide is an intracellular initiator of cell proliferation in lymphoid and hematopoietic tissue.

- 0819 *IN VITRO* DIFFERENTIATION OF A MURINE PLASMOCYTOMA REVEALING TWO PHENOTYPICALLY STABLE STAGES. (Fr.) Paraf, A. (Inst. Molec. Biol., Paris, France), M. A. Moyne, J. F. Duplan, R. Scherrer, M. Stanislawski, M. Bettane, L. Lelievre, P. Rouze and J. M. Dubert. *C R Acad Sci* 271(10):839-842, 1970.

A partially reversible phenomenon of cell differentiation characterized by two phenotypically different stages was established *in vitro* in a murine plasmacytoma. The original tumor (MOPC 173) maintained in BALB/c mice was cultivated *in vitro* on Earl's media with added yeast extract, lactalbumin, vitamins, calf serum and tris-buffered mouse embryo extract. The developed cell cultures were subjected to trypsin digestion a few weeks later and placed in similar media without embryo extract but containing 2% serum (to enhance the development of epithelial cells) or 10% serum (to favor the development of fibroblastic type cells). Two distinctive cell lines were thus obtained by differential trypsin treatment: a fibroblastic line, susceptible to trypsin hydrolysis, with oncogenic properties and containing large numbers of type A and about 1% of type C virus-like particles; and an epithelial cell line which was not susceptible to trypsin but was dissociated by EDTA and which had no oncogenic properties and contained no virus-like particles. The epithelial cells were able to become fibroblastic when transferred into media favorable for fibroblastic cell cultivation.

- 0820 BRONCHOALVEOLAR CANCER OR PULMONARY ADENOMATOSIS (JAAGSIEKTE) OF SHEEP. (E.) Enchev, S. (Vetr. Inst. Infect. Parasit. Dis., Sofia, Bulgaria). *Neoplasma* 17(4):415-425, 1970.

The lungs, pulmonary lymph nodes and viscera of 272 sheep and lambs afflicted with histologically demonstrated pulmonary adenomatosis were examined to determine if the condition is essentially neoplastic. Macroscopic features observed in pulmonary adenomatosis included intrapulmonary spreading and metastases in the lung lymph nodes in 73% and 8% of specimens. In 66% of the cases necroses were found in the lungs. Changes most often took the form of papilliferous adenoma, and usually originated in the bronchiolar epithelium. Metastatic foci showed a more malignant growth pattern, often resembling adenocarcinomas. On the basis of observed metastasis, necrosis and cellular atypism, it seems that pulmonary adenomatosis of sheep should be classed with neoplastic diseases.

- 0821 THE MODE OF SPREAD OF HODGKIN'S DISEASE TO THE SKIN. (E.) Benninghoff, D. L. (U. New York Downstate Med. Ctr., Brooklyn), A. Medina. *Cancer* 26(5):1135-1140, 1970.

Ten cases of Hodgkin's disease with definite subcutaneous involvement were reviewed to determine the mechanism of the skin invasion. The site of skin involvement among the 10 patients was random (skin or subcutaneous tissues of the head, arm, chest, and thigh), but a close relation existed between the site of initial lymph node involvement and the site of subsequent skin involvement which always occurred in the drainage area of extensively involved lymph nodes. The mechanism of skin involvement is a passive one in which the neoplastic cells are carried to the skin with a backflow of lymph resulting from a lymph node obstruction. Retrograde lymphatic spread of Hodgkin's disease constitute a major mechanism of its spread.

- 0822 METASTASIS: QUANTITATIVE ANALYSIS OF DISTRIBUTION AND FATE OF TUMOR EMBOLI LABELLED WITH ^{125}I -5-IODO-2'-DEOXYURIDINE. (E.) Fidler, J. (Sch. Dent. Med., U. Pennsylvania, Philadelphia). *J Nat Cancer Inst* 45(4):773-782, 1970.

A technique for quantitative studies of metastasis using young adult mice given i.v. injections of 10^5 pure melanoma cells grown in tissue culture and labeled with ^{125}I -5-iodo-2'-deoxyuridine is described. Mice were killed 2-3 wk after inoculation with the labeled cells, and the distribution and disposition of labeled tumor emboli were examined. Since the label was released only after cell death and was poorly reutilized and quickly eliminated, organ radioactivity represented almost exclusively the number of live cells present when the animals were killed. The lung contained most of the tumor cells in mice killed at all intervals. Some tumor cell emboli recirculated. Tumor cells in the lung decreased in numbers at about 5 min post injection. Tumor cells died rapidly, and about 1% of cells survived after 24 hr. About 400 melanoma cells were in the lung after 14 days, and those yielded an average of 78 metastases. Metastases could readily be established by a very few surviving tumor cells.

- 0823 PAPILLARY CARCINOMA OF THE THYROID: DEVELOPING PATTERN OF METASTASIS. (J) Noguchi, S. (Noguchi Thyroid Clin. Beppu, Japan), A. Noguchi and N. Murakami. *Cancer* 26(5):1051-1060, 1970.

The developing pattern of metastasis was determined by histological examination of the excised lymph nodes from 57 patients with papillary adenocarcinoma of the thyroid (metastasis was evident in 90% of these cases). A majority of the metastases (57%) were small (less than 3 mm in diameter); there was a correlation between the size of the primary tumor and the number of metastases, but no relation between the localization of primary tumors and the

nce or distribution of metastases was suggested. The sequence of metastatic concentration was pretracheal and paratracheal nodes, deep lower and lateral, and deep upper submandibular nodes for patients with small numbers of metastases, and pretracheal and paratracheal, paraglandular and deep per cervical, deep lower and lateral cervical, and submandibular nodes for patients with more extensive metastases. The paratracheal nodes appear to be most susceptible to metastasis of papillary thyroid carcinoma, regardless of the location of the primary tumor.

- 24 TUMOR GROWTH INHIBITING EFFECT OF JB-1 ASCITIC FLUID: I. AN *IN VIVO* INVESTIGATION (E.) Bichel, P. (Cancer Res. Inst., Aarhus, Denmark). *Europ J Cancer* 6(9):291-296, 1970.

mitotic indices and growth rates of a transplantable ascitic tumor (JB-1) were determined in mice after removing the ascitic fluid and replacing it with fresh cell-free tumor ascites or with "normal ascites" from non-tumorous mice. Three days after inoculation of the tumor the mitotic index peaked at 3-4%, then dropped off to 1.5% on day 5 or 6, and decreased slowly until the death of the animal. Aspiration of the tumor on day 10 followed by injection of tumor ascites or normal fluid twice daily raised the index to 3% from which it again decreased. Methylcine treatment on the second day after aspiration revealed more tumor cells in metaphase in mice subjected to total aspiration (5%) and in those receiving "normal ascites" after aspiration (6.5%) than in mice receiving tumor ascites after aspiration (2%) or in controls (1%). When tumor ascitic fluid was injected for only 2 days after aspiration, the mitotic index increased after discontinuation of the injections (to 2.2%), indicating that the tumor cells were capable of resuming accelerated growth. Inhibition of recurrent growth following daily injections of tumor ascites suggests that a humoral mitotic factor might be involved in the growth regulation of this tumor system.

SUBJECT INDEX

- 2-ACETYLAMINOFLUORENE
DERIVATIVES, RADIOACTIVE PRECURSOR
INCORPORATION, RNA AND DNA SYNTHESIS
(0408)
- ACTINOMYCIN
DNA SYNTHESIS, SV40 VIRUS (0662)
- ADENOCARCINOMA
COLD, URETEROSIGMOIDOSTOMY, MAN
(0825)*
EMBRYONAL, TESTS, CHILDREN (0746)
FERTILITY, ENDOMETRIAL HYPERPLASIA
(0743)
METASTASIS, THYROID, HUMAN
(0823)
PAPILLARY, GENETIC PREDISPOSITION,
FAMILIAL OVARIAN CARCINOMA (0808)
- ADENOMA
BRONCHO-ALVEOLAR CANCER, SHEEP (0820)
GASTRIC, N-METHYL-N-NITROSO-N'-
ACETYLUREA, RAT (0483)
- ADOLESCENCE
RAPID BONE GROWTH, ACUTE MYELOID
LEUKEMIA (0375)
- ADRENAL GLAND
CARCINOMA, CUSHING'S SYNDROME,
BILATERAL HYPERPLASIA, HORMONAL
THERAPY (0741)
CARCINOMA, FISSION NEUTRON IRRADIATION
(0532)
CARCINOMA, HUMAN, STEROID ANALYSIS
(0782)
ENDOCRINE LESION, URETHANE (0498)
NECROSIS, 7,12-DIMETHYLBENZ(A)ANTHRA-
CENE, RAT (0438)
- ADRIAMYCIN
BLASTOGENESIS IN HUMAN LYMPHOCYTES,
MUTAGENESIS IN HUMAN LYMPHOCYTES
(0699)
- ADSORPTION
ADENOVIRUS TYPE 7, ERYTHROCYTE (0614)
- AFLATOXIN
ASPERGILLUS FLAVUS, EFFECT OF
TEMPERATURE (0519)*
BI, ACUTE TOXICITY, KUPFFER CELL
HYPERPLASIA, BILE DUCT EPITHELIUM,
HAMSTER (0517)*
BI, B2, G1, G2, COUMARINS, FURAZOLIUM,
GUINEA PIG, HYPERSENSITIVITY (0424)
BI, ONA LIVER, RATS (0427)
BI, MICROSMAL HYDROXYLASE,
3,4-BENZOPYRENE (0428)
DIETARY, LIVER INJURY, RHESUS MONKEY
(0426)
MYCOTOXINS, TUMORIGENESIS, REVIEW
(0388)*
OILSEED PROTEINS, ANIMAL FEED,
TOXICITY, REVIEW (0387)*
PALMOTOXINS, EMBRYO LIVER (0425)
PEANUTS, DIETETICS, REVIEW (0386)*
- AGE
7,12-DIMETHYLBENZ(A)ANTHRA-
CENE, 3-METHYLCHOLANTHRENE, RAT, MOUSE
(0436)
PERINATAL PERIOD, TUMOR PROFILE,
URETHAN INDUCTION (0496)
TEEN-AGE PATIENTS, CYTOLOGIC ATYPIC,
CARCINOMA OF THE CERVIX (0744)
TUMOR SPECTRUM, URETHAN (0492)
- VARIATION, RH NEGATIVITY, LEUKEMIA
(0801)
- AGGLUTINATION
TRANSFORMED CELLS, SIMIAN VIRUS 40,
ADENOVIRUS TYPE 12, ORNITHINE,
LEUCINE POLYMER (0661)
- AIR POLLUTION
BRONCHOGENIC CARCINOMA, EPIDEMIOLOGY,
CZECHOSLOVAKIA (0768)*
CARCINOGENS, BRONCHIAL CARCINOMA,
HYDROCARBONS (0461)
LUNG CANCER, SMOKING, ITALY (0383)*
- ALDRIN
TUMORIGENICITY, DIELDRIN, ENDRIN
(0421)
- ALKYLATING AGENT
N-DIAZOACETYLGLYCINAMIDE,
N-DIAZOACETYLGLYCINE HYDRAZIDE,
CARCINOGENICITY, MOUSE (0401)
THYMUS, DNA, THERMAL DENATURATION,
CALF (0422)
- AMELOBLASTOMA
ODONTOGENIC TUMORS, ENZYME ACTIVITY
(0784)
- 4-AMINO-2',3-DIMETHYLAZOBENZENE
BINDING, LIVER PROTEIN, RAT (0432)
- AMINO ACID
ACCEPTOR RNA, AVIAN MYELOBLASTOSIS
VIRUS, AMINOACYLATION CAPACITY
(0585)
LEUKEMIC LYMPHOBLASTS, TRANSFER RNA
(0790)
- AMP
BONE MARROW, THYMUS, MITOSIS, RAT
(0818)
- ANEMIA
GASTRIC CARCINOMA, VITILIGO (0777)
- ANTIBODY

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain two-hundred abstracts and twenty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume IX covers the scientific literature published from July 1970 through June 1971. A cumulative subject and author index for Volume IX will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows:

Carcinogenesis Abstracts
Etiology Area
National Cancer Institute
National Institutes of Health
Bethesda, Maryland 20014

Use of funds for printing this publication
approved by the Director of the Bureau of
the Budget on July 25, 1967.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotrophic hormone	mg	milligram(s)
ADP	adenosine diphosphate	min	minute(s)
AMP	adenosine monophosphate	ml	milliliter(s)
ATP	adenosine triphosphate	mm	millimeter(s)
C	degrees centigrade	MTD	maximum tolerated dose
cm	centimeter(s)	ng	nanogram (10^{-9})
CNS	central nervous system	pg	picogram (10^{-12})
cpm	counts per minute	p.o.	orally
DNA	deoxyribonucleic acid	ppm	parts per million
e.g.	for example	r	Roentgen
g	gram(s)	RBC	red blood cells (erythrocytes), red blood count
µg	microgram(s)	resp.	respectively
hr	hour(s)	Rev.	review (only in citations)
i.m.	intramuscular	RNA	ribonucleic acid
i.p.	intraperitoneal	s.c.	subcutaneous
IU	international unit(s)	sec	second(s)
i.v.	intravenous	U	unit(s)
kg	kilogram(s)	UV	ultraviolet
LD ₅₀	median lethal dose(s)	WBC	white blood cells (leukocytes), white blood count
m	meter(s)	wk	week
M	molar	wt	weight
mEq	milliequivalent(s)	yr	year(s)
mM	millimolar		
µM	micromolar		
mC, µC	milli-,microcurie(s)

- 831 TRANSFER RNA METHYLASES AND CANCER. (E.) Craddock, V. M. (MRC Lab., Carshalton, Surrey, England). *Nature* 228(5278):1264-1268, 1970.

The experimental basis and the possible significance of changes in activities of nucleic acid methylases in tumors are reviewed. The tRNA methylases alkylate each of the 4 major bases and also the 2' position of the ribose moiety. In normal conditions, tRNA of a given species as isolated is fully methylated *in vivo*, but because the methylases are species specific, the incubation of tRNA from one species with methylases from another species can lead to further methylation; for this reason, activities of methylases in tumors have been studied by use of other than normal substrates. Changes in methylase activities in tumors may involve a change of specificities so that different proportions of bases are methylated, or there may have been an alteration in tRNA transcription, which could result in an altered substrate for the methylases. Measurement of methylated bases in urine from patients with leukemia often show an increased excretion of 7-methylguanine or 8-hydroxy-7-methylguanine, but this is not general among cancer patients with solid tumors. Studies with ¹⁴C-labeled bases and analysis of isolated tRNA in laboratory animals have confirmed that methylation is often altered in malignancy and high excretion of methylated bases in cancer patients is probably not an artifact due to increased cell death and degradation. The carcinogenic event associated with ethionine might be due to methylation of bases by way of S-adenosylethionine. The biochemical consequences of altered methylation may be due to alterations in binding interactions or codon recognition, which may result in variation of synthesis of some protein regulator of differentiation and other protein synthesis. - 832 MALADIES OF DEREPRESSION: PATHOLOGICAL, OFTEN MONOCLONAL, DEREPRESSION OF PROTEIN FORMING TEMPLATES. (E.) Waldenström, J. (Allmänna Hosp., Malmö, Sweden). *Schweiz Med Wschr* 100(51):197-2206, 1970.

The production of proteins by neoplastic and paraneoplastic cell systems from various sites are reviewed. Hypercalcemia is among the paraneoplastic phenomena observed in patients with malignant disease. A number of similar paraneoplastic symptoms may be explained as ectopic formation of polypeptide hormones. Since templates for the synthesis of polypeptides are present in a dormant, repressed state in the genome of all cells, it seems possible that ectopic polypeptide formation in neoplastic and paraneoplastic systems is a phenomenon of derepression of fetal protein synthesis. Support for this hypothesis comes from the finding that a fetal protein, fetuin, is produced by malignant hepatoma cells. Fetal Hgb globulin has been detected in large amounts in a patient with thalassemia; placental isoenzyme of alkaline phosphatase has been found in sera from 27 patients with lung, liver, and ovary tumors. Water intoxication, which appears as a paraneoplastic concomitant in some carcinoma cases, has been found to be due to ectopic formation of an antidiuretic hormone. The pituitary

hormone ACTH and melanophore stimulating hormone are produced by various carcinomas. Other hormones produced ectopically by tumors, perhaps as a result of derepressed fetal polypeptide systems, include calcitonin, amyloid, erythropoietin, Bence-Jones protein, cold agglutinin, and monoclonal cryoglobulins. It has recently been shown that tumors arising from immunocytes produce monoclonal proteins; it may be that in such clones of cells only 1 protein template is activated. Many of the instances of ectopic protein synthesis listed above appear to represent a monoclonal derepression of fetal protein forming templates. (51 references)

- 0833 CARCINOGEN BINDING BY CELL PROTEINS AND THE "DROP OUT" HYPOTHESIS. (Rus.) Bannikov, G. A. (Inst. Experim. and Clin. Oncol. Acad. Med. Sci. USSR). *Vop Onkol* 16(9):115-121, 1970.

The role of carcinogen binding by cell proteins which is associated with the disappearance of specific regulatory proteins and which produces energetic shifts leading to oncogenesis is reviewed. The target organ specificity of such compounds is illustrated by hepatocarcinogens such as 4-dimethylaminoazobenzene (DAB), fluorenylacetylamide (FAA) and others. DAB is bound by a narrow group of soluble liver proteins referred to as the *h*-fraction, which is characterized by a particularly high methionine content (15 residues/mole) in its amino acid composition; this fraction has been proven to be the binding site of the azodye, and the evidence suggests that covalent linkage is involved. The kinetics of the carcinogen-protein binding show that the accumulation of DAB in rats maintained on a DAB containing diet is linear during the first 3-5 wk and reaches a peak, coinciding with the occurrence of greatest histological alterations in the liver tissue and with the highest mortality rate; the accumulation then decreases to zero at the appearance of the tumor. A decrease in *h*-protein seems to occur along with the decrease in carcinogen binding rate after the peak stage; this decrease in *h*-protein appears to be correlated with the degree of deviation of the preneoplastic tissue from normal liver tissue. A correlation between carcinogenicity and the rate of accumulation of carcinogen in the susceptible tissue has been found for various carcinogens. Two common features associated with the action of various chemical carcinogens are: 1) the formation of a covalent link between the carcinogen and a certain group of soluble proteins of the susceptible tissue and 2) the disappearance, referred to as the "drop out", of these proteins from within the carcinogen-induced neoplastic tissue. - 0834 ESTROGEN-BINDING AND THE HORMONE RESPONSIVENESS OF TUMORS. (E.) King, R. J. B. (Imp. Cancer Res. Fund, London, England), J. A. Smith and A. W. Steggles. *Steroidologia* 1(2):73-88, 1970.

The relation between hormone responsive and unresponsive tumors and estrogen binding is reviewed. Experimental systems used for hormone responsive studies include dimethylbenzanthracene-induced mammary adenocarcinomas, estrogen-induced kidney and pituitary

tumors, the BR6 pregnancy dependent tumor and androgen dependent mammary tumors. In the rat mammary tumor, over 80% of the label after one injection of 6,7-³H-estradiol was found in the nuclear fraction and appeared to be attached to a non-histone protein. Cytoplasmic estradiol seemed to be associated with a high molecular wt protein. Mammary tumors from patients who do not respond to adrenalectomy appear to bind less estrogen than tumors which do respond to the operation. In general, unresponsive tumors appear to be biochemically more active than responsive ones. (54 references)

- 0835 SUNLIGHT AND THE AETIOLOGY OF MALIGNANT MELANOMA: A SYNTHESIS. (E.) Lee, J. A. H. (Sch. Publ. Hlth. Commun. Med., U. Washington, Seattle) and J. M. Merrill. *Med J Aust* 57(18):846-851, 1970.

Data on the anatomical distribution and pathological type of malignant melanoma was collected, and the correlation of these factors with exposure to sunlight was examined. Lentigo maligna, a skin condition which degenerates into invasive malignant melanoma in approximately 33% of cases, is primarily a feature of skin which has been exposed to sunlight for long periods. Incidence rates for New Zealand show that 100 cases of lentigo maligna occurred/million population/yr for persons 55-yr-old, as compared with England and Wales where the incidence rate for 55-yr-olds was 15 cases/million/yr. Superficial spreading melanoma, which makes up most cases of melanoma of the female lower limbs, has excessive incidence on areas of the leg exposed to sunlight. Although there is evidence that the incidence of malignant melanoma itself is related to the degree of exposure of populations to sunlight, attempts to relate distribution of malignant melanoma to exposed sites by taking histories from individuals have not been fruitful. No evidence has been found that specifically exposed areas of the body, such as the head and neck, have unusually high incidences of malignant melanomas. However, malignant melanoma of all sites has a higher incidence in equatorial countries (e.g., 164 cases/million population/yr in New Zealand) than in northern countries (e.g., 18 cases/million/yr in Denmark). Nodular melanoma, tumors which are uniformly invasive and which involve the worst prognosis of the melanoma conditions, are not particularly associated with sunlight exposure. It has been suggested that, since exposed areas of the body are not necessarily the site of increases in incidence of malignant melanoma, sunlight may exert an indirect effect on malignant melanoma pathogenesis. A systemic effect associated with latitude might involve heat, perspiration or minor trauma associated with rubbing clothing. A circulating factor which is sensitive to sunlight may be operative in the increased incidence of malignant melanoma (e.g., chalones, which control the rate of mitoses in the skin and which be modified by exposure to sunlight. (41 references)

- 0836 THE MALIGNANT TUMOR RISK FROM RADIUM BODY BURDENS. (E.) Goss, S. G. (Radiol. Protect. Service, Belmont, Sutton, Surrey, England). *Health Phys* 19(6):731-737, 1970.

Studies on malignancy risk as a result of exposure to radium in supposedly "acceptable" doses conducted by 2 groups (MIT and ANL) are discussed. These studies have asserted that large safety factors operate for the presently-accepted maximum permissible dose of 0.1 μ C of ²²⁶Ra; it was implied that there are practical thresholds of the body burden of radium at higher levels. However, these studies were conducted on small sample populations of radium-exposed persons, only half the populations at risk were located and studied, and the conclusions were based on oversimplified assumptions on the mechanism of tumorigenesis by radium, which is, in fact, obscure. The studies conclude that for the induction of tumors by radium, a threshold level exists above that given by the present maximum permissible level for ²²⁶Ra in the body; however, insufficient attention was paid to the fact that the possibility of tumor incidence at low radium doses is small enough for no tumors to have appeared in the few exposed persons examined. The threshold levels arrived at by the studies might still be unacceptable if exposed to larger populations. Since a high proportion of the populations studied are still alive, many of the histories from these populations are incomplete; the higher than expected tumor incidence manifested in 1 study suggests that the range of radium-induced tumors may be wider than expected. Dose-response curves for radium were calculated in the absence of theory to indicate which dose parameter is appropriate for defining the curve. It is concluded that no factor of safety or high threshold of radium body burden has been shown to exist, and that the present maximum permissible level for ²²⁶Ra in the body is, if anything, too high. - 0837 COMMON PROPERTIES OF THE ONCOGENIC RNA VIRUSES (ONCORNAVIRUSES). (E.) Nowinski, R. C. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), L. J. Old, N. H. Sarkar and D. H. Moore. *Virology* 42(4):1152-1157, 1970.

The biological, biochemical, and structural properties of the oncornaviruses, or oncogenic RNA viruses, are reviewed. Biologically, all oncornaviruses are oncogenic to some degree in their natural hosts, which include most vertebrates in which thorough investigations for the presence of the viruses have been made. Oncornaviruses commonly induce leukemias, sarcomas and mammary tumors. Congenital infection by oncornavirus is more frequent than postnatal infection; some oncornavirus characteristics show Mendelian inheritance. Oncornaviruses do not produce a cytopathic effect in the infected cells of their hosts. Oncornaviruses have a 60-70S RNA, and a small basic protein as the prominent group-specific antigen; they rarely show hemagglutinating activity *in vivo*. Actinomycin treatment usually inhibits the production of oncornaviruses by chronically infected cells *in vitro*. Oncornaviruses contain an enzyme which produces DNA from a viral RNA template. Structurally, the oncornaviruses display a spherical internal structure, as opposed to a cubic or helical symmetry. The nucleoprotein of the oncornaviruses is apparently a 30 A strand which is free in disrupted particles and takes a helical form in intact viruses. (47 references)

0838 SOMATIC HYBRIDIZATION AND CELL MALIGNANCY. (Fr.) Barski, G. (Inst. Gustave Roussy, Villejuif, France). *Bull Cancer* 57(2):185-194, 1970.

Experimental data on malignant and nonmalignant cell hybridization accumulated since 1960 are reviewed and the complexity of factors determining the properties of daughter cells is discussed. When N2 cells (clone NCTC 2 555) without tumorigenic properties and N1 cells (clone NCTC 2 472) with tumorigenic properties are fused and injected into test animals, sarcomas are produced. The hybridization of the N1 and N2 cells produced M cells which in *in vitro* experiments showed a tendency to malignancy, and when injected into the syngeneic mice, the nonmalignant N2 disappeared, and the tumors formed were composed of the hybrid M cell. These were characterized by a cellular morphology intermediate between that of N1 and N2, a cumulative karyotype of N1 and N2 with a tendency to chromosome deletion, and a high tumorigenic capacity similar to that of N1. However, the hereditary mechanisms of cancerization could not be compared to the Mendelian rules; there are no unique recessive or dominant features. A merging of several modifications such as the loss of certain control mechanisms and the acquisition of new properties in cells subjected to transformation by oncogenic viruses seems to occur. (20 references)

0839 MALIGNANT TUMORS IN ORGAN TRANSPLANT RECIPIENTS. (E.) Penn, I. (U. Colorado Med. Ctr., Denver). *Recent Results Cancer Res* 35:1-51, 1970.

Experimental work to date concerning the connection of malignancy and immunologic insufficiency in animals and man was reviewed, with emphasis on malignancy development in organ homograft recipients. Data were compiled on cases in which tumors were present before or at the time of organ transplantation, as well as on cases in which tumors were transmitted with the transplanted organs. The possibility of tumors arising *de novo* subsequent to kidney transplantation was discussed. Evidently reduced immunocompetence occurring spontaneously or produced iatrogenically are associated with increased incidence of malignancy, a finding which accentuates the danger of treating cancer by transplantation of affected organs. In view of the importance of accurate statistical data on malignancy associated with organ transplantation, an informal registry of such malignancies has been established in Denver. (186 references)

0840 EVIDENCE FOR HUMAN CANCER IMMUNITY: A REVIEW. (E.) Piessens, W. F. (Massachusetts Gen. Hosp., Boston). *Cancer* 26(6):1212-1220, 1970.

Evidence for tumor specific antigens (TSA) operating in humans was reviewed. Spontaneous regression of lesions, disappearance of distant metastases after excision of the primary tumor mass, relapse after years of "cure", and large numbers of tumor cells

present in the blood during surgery without development of metastases suggested that TSA exists in human systems. Further evidence may be provided by the association of immunosuppressive therapy and tumor development in human subjects. Homografted tumors in human patients rarely grow successfully; it has been suggested that when they do, their growth is explained by immunotolerance or immunosuppression. Circulating tumor-directed antibodies have been demonstrated in humans with Burkitt's lymphoma and malignant melanoma; the antigenicity of neuroblastoma in humans has also been demonstrated. Tumor-specific, cell-mediated immunity elicited by antigens on the membranes of tumor cells have been detected in malignant melanoma, acute leukemia, and breast tumors. (125 references)

0841 IMMUNOLOGICAL ASPECTS OF CANCER: I. IMMUNOLOGICAL FACTORS AFFECTING TUMOUR GROWTH. (E.) Klein, G. (Karolinska Inst., Stockholm, Sweden). *Brit Med J* 4(5732):418, 1970.

Studies of the antigenic properties of human tumors were briefly reviewed. Immune responses by the host against tumor-associated antigens have been demonstrated in Burkitt's lymphoma, nasopharyngeal carcinoma, osteogenic sarcoma, malignant melanoma, neuroblastoma and carcinoma of the colon and bladder. Cell mediated immunity usually plays the major part in the immune response; humoral antibodies are either ineffective or block the rejection reaction. The antigens responsible for the immune response probably are located on the outside of the cell membrane. Tumor cells in a human host might escape rejection by immune mechanisms by changing or losing their antigenic makeup, as may occur in tumors induced by RNA viruses. Alternatively, tumor cells may survive due to an immunosuppressed state in the host brought about by thymectomy, irradiation, or treatment with antilymphocyte serum. Insufficient release of antigen before the tumor has reached an irreversible stage of development might also account for the survival of tumor cells in a human host. (no references)

0842 THE IMMUNOLOGICAL FUNCTION OF THE THYMUS IN THE DEVELOPMENT OF NEOPLASIAS. (Fr.) Potop, I. (Acad. Med. Sci. Rumania, Bucharest). *Rev Roum Endocr* 7(4):305-314, 1970.

A review of the role of the thymus in carcinogenesis is presented. The thymus intervenes in immunological phenomena by means of the lymphoid cells, and thus dictates the immunological response of the embryo and neonate. These thymic lymphocytes may originate either from a migrating colony, or from a metaplasia. The influence of the thymus upon the number of circulating lymphocytes may be due to lymphocytes leaving the thymus, a hormone secreted by the thymus which stimulates proliferation of lymphocytes in the lymph glands and in the spleen, or by interaction with the growth hormones. A thymectomy effected 24 hr after birth decreases the immunological response in the mouse and rat to cutaneous tumors and foreign grafts. In the adult animal thymectomy decreases the immunological response

to irradiation; sensitivity to radioactivity is more pronounced in the young animal (15-45 days old). From experiments investigating the production of antibodies, it was concluded that the thymus intervenes in immunological functions by interaction with hypophyseal hormones. A thymic graft can reestablish the immunological activity of irradiated or irradiated and thymectomized animals. The administration of calf thymus increases the number of lymphocytes in thymectomized animals, prevents the appearance of the wasting syndrome and protects the animals against viral infection. Nevertheless, in the case of certain viruses (Gross and Moloney), thymectomy produces contrary effects. The production of tumors by carcinogenic agents in thymectomized animals is discussed, and immunoprophylactic measures are envisioned. (112 references)

0843 IMMUNOLOGY OF TUMORS. (E.) Surjan, M. (Natl. Inst. Publ. Hlth., Budapest, Hungary). *Ther Hung* 18(2):55-62, 1970.

Malignant transformation of cells is usually accompanied by the acquisition of tumor-specific antigens which elicit an immune response from the host. Such tumor-specific antigens have been demonstrated for all virus-induced tumors, and for most chemically induced tumors. The strongest antigenicity in tumors induced by chemical carcinogens is found in tumors induced by cyclic hydrocarbons and by methylcholanthrene, and the weakest antigenicity is found in tumors induced by cellophane or multipore membrane. Urethan-induced adenomas have no antigenicity at all. As a rule, the stronger the antigenicity of the chemically induced tumor, the earlier the tumor appears. Among virally induced tumors, those induced by RNA and DNA viruses produce tumor-specific antigens. Active antiviral immunity has been shown to protect against tumors induced by the same virus. Spontaneous tumors are usually of weak antigenicity. While cell-mediated immunity is effective against many antigenic tumors, humoral immune responses vary with different tumor types. In some cases humoral antibodies may enhance tumor growth rather than inhibit it. Congenital or acquired immune deficiency, decline of antibody production with age, and iatrogenic immunosuppression may lead to the promotion of tumor growth. Sera from human subjects with Burkitt's lymphoma have been shown to possess tumor antibodies. Immunotherapy may prove to be a useful tool in the management of malignant disease in humans. (52 references)

0844 HORMONAL DEPENDENCE OF BRAIN TUMORS. (Rus.) Babchin, I. S. (Leningrad, USSR). *Vop Onkol* 16(10):29-31, 1970.

The disruption of hormonal balance and steroid equilibrium may induce mutagenic effects in the brain cell and lead to neoplastic growth. Several examples of such neoplasia are reviewed. Neurinoma of the VIII nerve, with an incidence in females 2 times as high as in males, develops usually at the age of 25-35 yr in association with pregnancy, delivery or nursing. Pinealoma occurs in males 5 times more often than in females; cerebellar medul-

loblastoma occurs twice as often in boys as in girls during the early prepuberal age. The role of hormones in inborn heterotopic brain tumors with a teratoid, dermoid or epidermoid character is still uncertain; these tumors become clinically detectable only at the age of puberty. The considerable importance of hormonal factors (either evident or disguised) in the polyetiological genesis of brain tumors is emphasized. (18 references)

0845 PATHOLOGICAL ALTERATIONS OCCURRING IN ORGANS AND TISSUES FOLLOWING CONTRAST MEDIA AND RADIOACTIVE ISOTOPE APPLICATION. (Ger.) Oehlert W. (no affil). *Langenbecks Arch Chir* 327:229-237, 1970.

Tissue alterations induced by radioactive contrast media are reviewed. Accumulation of thorotrast leads to a damage of the reticuloendothelial system with subsequent cell proliferation, and of the surrounding storage cells where α -particles may migrate and induce specific cell and nuclear alterations. Similar effects are produced by cold and hot lymphography (lipiodol). The oily contrast medium leads to reactions against foreign bodies while ^{131}I causes radiation damage to the surrounding tissue. Occasionally formation of giant endothelial cells within the connective tissue occurs, and leads to a total devastation of the lymph nodes. The cold or "hot" contrast media (lipiodol) may enter the lung in some cases by the thoracic duct, and the lipid accumulates within the lining alveolar cells. The ^{131}I -lipiodol-induced alterations in the lung usually consist of 2 stages as in the case of thorotrast. The accumulation of lipid within the alveolar cells leads to the formation of polynuclear giant cells and proliferation of the connective tissue; the β -particles and γ -radiation from ^{131}I induce an increasing radiation fibrosis of the lung parenchyma. (5 references)

0846 CHANGES IN THE CURRENT CONCEPT OF MALIGNANT MELANOMA. (E.) Mishima, Y. (Wakayama Med. U., Japan). *Curr Probl Derm* 3:51-81, 1970.

Some of the clinical and biological distinctions of nevocytic and melanocytic neoplastic processes are reviewed. "Melanocytoma" includes all tumors derived from junctional or dermal melanocytes and excludes pigment tumors made up of nevus cells. The precancerous stage of epidermal melanocytoma usually develops from lentigo senilis or the melanotic freckle of Hutchinson and lentigo maligna; the criteria of malignant transformation into malignant melanocytoma is based on whether the proliferation of anaplastic melanocytes is limited within the epidermal structure or has invaded the dermis beyond the line of the basement membrane. "Dermal melanocytoma" or the cellular blue nevus refers to pigment cell tumors that develop from melanocytes which have not reached their permanent location in the basal layer. The term malignant nevocytoma refers to the malignant melanoma arising from nevus cells of generally junctional type. Its clinical appearance is a rapidly growing, anaplastic tumor which may or may not show melanin hyperpigmentation. The melanosomes of malignant nevocytoma appear to be cigar-shaped

odies 650-950 μ m x 300-400 μ m and are different from melanosomes of malignant melanocytoma. The malignant melanoma cells often show autophagic activity in areas of focal degradation and necrosis and occur more extensively in malignant nevocytoma than in melanocytoma. (36 references)

0847 CARCINOMA OF THE TONGUE. (E.) Westbury, G. (Westminster Hosp., London, England). *Brit J Hosp Med* 4(5):673-678, 1970.

The incidence, etiology and pathology of carcinoma of the tongue were investigated. Tongue cancers make up 1% of Western malignancies, while the incidence in parts of India is 20%. The peak age incidence in Bombay is in the 40-45 yr age group, while those aged 55-75 yr are more often affected in England and the United States. Males are more often affected than females. Carcinoma of the tongue has been related to various environmental factors, including tobacco chewing, smoking, poor oral hygiene and dental irritation, and alcohol. In 1 study, 77% of patients with tongue cancers were smokers. Iron deficiency and the chronic superficial glossitis involved in tertiary syphilis have also been implicated as etiological factors in carcinoma of the tongue. The prevalent histological type of tongue carcinoma is squamous cell carcinoma, with adenocarcinoma of the salivary glands and metastatic carcinoma being among the rarer diagnoses. Leukoplakia conditions affecting the tongue have been related to carcinoma, with 12% of patients with leukoplakia developing carcinoma in 1 study. Carcinoma of the tongue was located on the anterior portion of the tongue 1.5 times more often than on the basal portion in 1 study, with most lesions being found on the lateral borders of the tongue. In advanced stages, the disease may extend deeply into the tongue musculature, the mandible, palate and larynx. Tongue carcinomas are often multicentric, and there may be a relationship between smoking and the likelihood of developing a second tumor. Lymph nodes are involved in many cases; distant metastases were observed in 5% of the cases in 1 study. Prognosis is directly related to the stage of the disease, and survival has improved in recent years with improvements in diagnostic techniques. (58 references)

0848 THE STIMULATION AND INHIBITION OF HEPATIC MICROSOMAL DRUG-METABOLIZING ENZYMES WITH SPECIAL REFERENCE TO EFFECTS OF ENVIRONMENTAL CONTAMINANTS. (E.) Fouts, J. R. (Coll. Med. U. Iowa, Iowa City). *Toxic Appl Pharmacol* 17(3):804-809, 1970.

Factors that should be considered in determining the stimulatory or inhibitory activity of environmental chemicals on hepatic microsomal drug-metabolizing enzymes and areas of research that have been neglected were noted. The amount of time required before pharmacological activity is detected varies among experiments, different species produce different responses as do the same species receiving the test drug by different routes (p.o., i.p., or s.c.). Inducers often contain inhibitory activity

(while inhibitors frequently cause an induction of the microsomal enzymes), and some test compounds affect only a few microsomal enzymes. Compounds that are rapidly metabolized or excreted must be given repeatedly before activity can be detected, and the effects on steroid metabolism or environmental interactions may be important in determining toxic effects of the compounds. Systems not requiring cytochrome P-450, some environmental toxins (tetraethyl lead), activity in nonhepatic tissues, and interactions between environmental toxins and food additives are relatively neglected areas of study. Additional information is needed on species differences (particularly the primates), on the effects of microsomal enzyme activity alteration on the action of drugs, and on effects of environmental contaminants on renal and biliary excretion. Changes in absorption or tissue and plasma protein binding, as well as the relation of placental structure differences to transfer of materials from mother to fetus should also be investigated. (19 references)

0849 HEPATIC CANCER AND MYCOTOXINS. (Fr.) Le Breton, E. (Cordeliers Sch. Med. Sci., Paris, France) *Ann Biol Clin* 28(3):203-208, 1970.

Reasons for the increase in the incidence of hepatic cancer in humans within recent years in temperate regions which have a high standard of living, as in France, are discussed. The evolution of cirrhosis of the liver toward a cancerous process is attributed to the ingestion of carcinogenic substances in the food such as mold toxins. Among recently discovered carcinogenic mycotoxins are luteoskyrine (from *Penicillium islandicum* which is a rice mold found in the tropical regions of Asia) and the aflatoxins. The latter was discovered by the observation of an acute hepatitis in turkeys after they had ingested some peanut cakes which were found to be contaminated with *Aspergillus flavus*. A number of aflatoxins have been discovered which have been separated chromatographically and their spectra determined under U.V. They were named aflatoxins B₁, B₂ (blue fluorescence) and G₁, G₂ (yellow-green fluorescence). The toxicity of aflatoxin affects all organisms and in the higher animals is manifested mainly in the liver, the toxic doses varying with the species. In the rat hepatocellular changes caused by aflatoxin result in inhibition of nucleic acid synthesis and compensatory hypertrophy of the liver occurs. DNA and RNA metabolism is discussed in this context. (8 references)

0850 ETIOLOGICAL ASPECTS OF SQUAMOUS CANCERS OF THE HEAD AND NECK. (E.) Wynder, E. L. (Amer. Hlth. Found., New York, N.Y.) *Jama* 215(3):452-453, 1971.

Various environmental factors associated with squamous cell cancer of the head and neck were reviewed. A close association has been established between tobacco usage and squamous cell cancer of the head and neck in virtually all sites. Cancer of the vocal cords was found to be predominantly related to cigarette smoking, while other head and neck can-

cers, including cancers of the oral cavity and pharynx, are equally strongly associated with pipe and cigar smoking. Data from India have indicated that tobacco and betel nut chewing is causally related to cancer of the mouth. In women, oral cancer was usually found to be located in the tongue or buccal mucosa. Cancer of the head and neck in sites other than the lip and vocal cord was strongly related to heavy alcohol consumption; however, the fact that most heavy drinkers also smoke made it difficult to assess the relative weights of smoking and drinking as etiological factors for these conditions. While no evidence that alcohol is carcinogenic *per se* exists, it was suggested that alcohol may potentiate the carcinogenic effects of tobacco smoke. Syphilis has been correlated with cancer of the anterior 2/3 of the tongue; and liver cirrhosis has also been correlated with cancer of the upper alimentary tract. The correlation of Plummer-Vinson's disease brought on by iron deficiency and cancer of the squamous tissue of the mouth and pharynx may suggest that cancer of the head and neck are sometimes associated with deficiency conditions. It has been shown that riboflavin deficiency can lead to atrophy and hyperkeratosis in the upper alimentary tract. The skin of riboflavin-deficient mice was found to be more susceptible to carcinogenic agents than the skin of normal mice. Heavy cigarette smoking apparently makes patients more likely to develop a second primary tumor in the oral cavity and upper respiratory tract. Furthermore, cessation of smoking and drinking after the appearance of the first primary tumor did not ensure that a second primary tumor will not develop. (no references)

- 0851 PRECANCEROUS CONDITIONS OF THE ESOPHAGUS. (Fr.) Mounier-Kuhn, P. (no affil), J. Gaillard, J. P. Haguenauer and P. A. Bernard. *J Med Lyon* (1197):1957-1963, 1970.

Precancerous states of the esophagus where the etiology is known or presumed and those of an unknown etiology were investigated. To the first category belong the cicatricial, the atonic wounds, and the inflamed lesions. The agent responsible for scarring is usually caustic soda or a product containing it, and cancer formation, which occurs only years later, is usually located at the stenotic area. This type of cancer may develop from other trauma such as hot food or acids and continuous infection due to stasis. Atonic wounds of the esophagus are more rare; a neoplasm may develop from a previously calcified ganglion. Both the above mentioned states may be regarded as precancerous. The 3 main esophageal syndromes giving rise to inflamed lesions are: peptic stenosis, megaesophagus, and esophageal diverticulum. Precancerous states of indeterminate etiology include: esophageal dysplasia during sideropenia, esophageal leukoplakia, and benign tumors. All these states have in common an esophagitis which favors the development of a cancer. Prophylactic as well as surgical treatment is discussed. (12 references)

- 0852 PATHOGENESIS OF CARCINOMA OF THE UTERINE CORPUS. (Bul.) Ivanov, I. I. (Med. Inst. Sofia, Bulgaria) and V. Makaveeva. *Akush Gynec [Sofia]* 9(5):413-418, 1970.

A review on the specific features in the development of endometrial carcinoma is presented. The interactions between the uterine mucosal epithelial cells and the environmental stroma undergo considerable alterations at the menopausal stage. The turnover of the endometrial epithelial cells occurring during sexual life ceases and the static conditions of these cells render them a susceptible target to endogenous carcinogenic factors generated by hormonal disorders. Thus the uterine mucosal epithelium becomes a potential site for malignant transformation. (14 references)

- 0853 THE GENESIS OF SOME EPITHELIAL CHANGES, SOMETIMES PRECEDING OR ATTENDING THE APPEARANCE OF CANCER OF THE CERVIX UTERI: A REVIEW OF COMPARATIVE AND EXPERIMENTAL DATA. (E.) Volfson, N. I. (Ministry Publ. Hlth., Leningrad, USSR). *Neoplasma* 17(5):541-555, 1970.

Intraepithelial cervical changes preceding or attending the appearance of invasive cancer of the cervix uteri that have been investigated are reviewed. The development of apparently immature endocervical stratified squamous epithelium (in the fourth decade of a woman's life, during pregnancy, and in the newborn) results from excessive estrogenic stimulation; the newly formed stratified squamous epithelium of infancy, childhood, and senility is identical to the normal mature stratified ectocervical epithelium (and may be derived from it). Hyperplasia of reserve cells, dysplasia, and carcinoma *in situ* of the cervix uteri display identical histogenesis, and the morphology in the cervical epithelium may reflect normal age-determined processes as well as certain pathological processes (carcinogenesis of the cervix uteri). - 0854 MALIGNANT TRANSFORMATION OF CELLS CULTIVATED *IN VITRO*: A MODEL OF CARCINOGENESIS WITH SPECIAL REFERENCE TO "SPONTANEOUS" MALIGNANT TRANSFORMATION. (E.) Briand, P. (Fibiger Lab., Kongens Lyngby, Denmark). *Danish Med Bull* 17(8): 217-225, 1970.

The metabolic, morphological, and growth characteristics of cells undergoing malignant transformation *in vitro* were reviewed. The architectural appearance of malignant cells *in vitro* may be distinctive; elongated spindle-shaped cells growing in several layers and forming aggregations have been found to be characteristic of malignant cells. In human cells, shifts from diploidy to heteroploidy have been found in association with malignant transformation. Changes in ploidy have been associated with malignant transformation in other cell systems. In cell cultures *in vitro*, growth

proceeds in phases: an initial proliferative stage, followed by a stage of sluggish growth, followed by a stage of rapid proliferation. The final phase has been suggested as being indicative of malignant transformation in human cell cultures. A characteristic feature of cancer metabolism is the large lactate accumulation; malignancy has also been found to be accompanied by increased glycogen metabolism in some tissue cultures. Glycolytic metabolism is usually associated with the initial phase of cell growth *in vitro*, while the final phase of rapid proliferation is marked by chromosomal changes. Whether malignant properties arise in the later phase is unclear; the changes observed in the various phases of cell growth may be either causes of malignant transformation or effects of prior malignant transformation. 0855 CHEMICAL MUTAGENS AS A POSSIBLE GENETIC HAZARD IN HUMAN POPULATIONS. (E.) Malling, P. V. (Oak Ridge Natl. Lab., Tenn.). *Amer Indust Hyg Ass J* 31(6):657-666, 1970.

Mutagenic chemical compounds, their uses by man, and their mutagenic pathogenicity in experimental systems were reviewed. Mutagenic compounds may produce lethal dominant or lethal recessive mutations, or may affect the morphology of the organism ingesting it without killing that organism. Two widely-used experimental systems for testing the mutagenicity of compounds are neurospora and mice, in which the production of dominant lethal mutations may be conveniently tested. Highly mutagenic chemical compounds include ethyl and ethyl methanesulfonate, which induce dominant lethals in mice, and N-methyl-N'-nitro-N-nitrosoguanidine, which is highly mutagenic and carcinogenic. Other chemical mutagens include 2-methoxy-5-chloro-9-[3-(ethyl-2 chloroethyl)aminopropylamino]-2,4,6-tris(1-aziridinyl)-1,3,5-triazine which induces nuclear-killing chromosome deletions and point mutations in neurospora. Mutagenic chemicals having widespread use in the human environment include nitrites and nitrates, some insecticides and herbicides, some antimalarial, anti-neoplastic, and antibiotic drugs (including Actinomycin D), and caffeine. The increasing use of mutagenic agents by men indicates that there is a risk of increasing genetic disease in the human population, although it is not always possible to extrapolate from known mutagenic effects on laboratory animals to mutagenic effects on men. 0856 SPONTANEOUS CHROMOSOMAL BREAKAGE AND HIGH INCIDENCE OF LEUKEMIA IN INHERITED DISORDERS. (E.) Schroeder, T. M. (Inst. Anthro., Human Genet., U. Heidelberg, Germany) and R. Kurth. *Blood* 37(1):96-112, 1970.

The association between chromosomal breakage and high leukemia incidence which has been observed in several diseases was reviewed; the diseases were ataxia telangiectasia, Bloom's syndrome, Fanconi's anemia, glutathione reductase deficiency, Kostmann's agranulocytosis, and pernicious anemia. In these diseases, the incidence of chromosomal aberrations,

including achromatic regions, chromatid and chromosome breaks, fragments, translocation figures, rings and dicentrics is high; and in all these diseases, it has been observed that patients contracting them are unusually likely to contract leukemia. A relation between chromosomal anomalies observed *in vitro* and hematological disorders *in vivo* has been shown for Fanconi's anemia and in glutathione reductase deficiency; this relationship depends on the stage of the disease, anomalies being restricted to immature red cells only when the disease involves the erythropoietic system. No *in vivo* studies have been performed on the relationship between *in vitro* and *in vivo* states in Bloom's syndrome or ataxia telangiectasia. In Kostmann's agranulocytosis, chromosome breakage has been demonstrated *in vivo* only. Culture conditions obscure the relation between *in vitro* findings and *in vivo* events in pernicious anemia. Apparently, many instances of negative findings for chromosomal abnormalities associated with these conditions are misleading and ignore evidence of abnormalities. Chromosomal breakage *in vitro* and *in vivo* is apparently the result of a primary genetically determined defect whose precise nature is unknown. The possibility that the cells are influenced *in vitro* to abnormal development remain. (88 references)

0857 THE ROLE OF MIGRANT POPULATION IN STUDIES OF SELECTED CANCER SITES: A REVIEW. (E.)

Kmet, J. (Int. Agency Res. Cancer, Lyon, France). *J Chron Dis* 23(5-6):305-324, 1970.

The incidence of cancer of various sites in migrant populations, as compared to incidences in stationary populations, was reviewed. Most of the data has been compiled on immigrants to the United States. Oral cancer rates are higher for Irish migrants to the U.S. than for Russian migrants, a finding which may relate to the role in oral cancer of excessive alcohol consumption. A high rate of oral and pharyngeal cancer for Swedish female migrants correlated with a high rate of cancer in these sites for native Swedish females as compared to males. All foreign-born males in one study had higher rates for esophageal cancer than did native born American males, while incidences for migrant females were more variable. Immigrant male Poles had mortality rates from esophageal cancer more than twice as high as non-immigrant males in Poland and in the U.S. Stomach cancer rates in all ethnic groups in the U.S. were higher than those for the native white population, highest risks being found for migrants from Poland and Czechoslovakia. Incidence rates for cancer of the large intestine and rectum among people migrating within the U.S. correlated more closely with rates for regions of most recent residence than with rates for regions of birth. Risks for colon and rectal cancer among Polish immigrants differed from risks incurred by the native Polish population, and conformed to those incurred by U.S. residents. No striking departure from native U.S. incidence rates for prostatic cancer or cancer of the ovary were found for migrant groups. Migrants from countries having higher or lower lung cancer rates than the U.S. showed lung cancer incidence

rates intermediate between those of the native country and the U.S. Immigrants to the U.S. from Russia, especially Jewish immigrants, showed an excess risk for leukemia. (52 references)

0858 SOME INTERCOUNTRY AND INTERGROUP DIFFERENCES IN HISTOLOGICAL TYPES OF CANCER. (E.)

Berg, J. W. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.). *J Chron Dis* 23(5-6):325-334, 1970.

Relationships in various geographic areas between the incidence and the histological origin of different carcinoma conditions were investigated in a survey of the available literature. Adenocarcinomas of the stomach may be distinguished into the diffuse and the intestinal type; the latter predominates in high-incidence areas in Latin America. Bantu people with low incidences of bowel cancer have relatively more colloid carcinomas. Mesotheliomas of the pleura and peritoneum are extremely rare, except in association with asbestosis, where they are common; and nasal and sinus adenocarcinomas are of high incidence among furniture workers exposed to wood dust. Cystosarcomas of the breast are more frequent in the Orient, while medullary and colloid carcinomas are more common in Japan. In England, seminomas of the testis are found in excess in rural areas, while other tumors are no more frequent in the country than in towns. Bantus were found to have a low incidence of gliomatous brain tumors compared to whites; however, they develop meningiomas at the same rate as whites. Negro children in the United States appear to be less susceptible to acute lymphatic leukemia than whites. (46 references)

0859 OIL AND CARCINOMA OF THE SCROTUM. (E.)

Kipling, M. D. (no affil). *Trans Soc Occup Med* 19(2):36-40, 1969.

The association of carcinoma of the scrotum with occupational exposure to mineral oils, and the incidence and pathology of carcinoma of the scrotum were reviewed. The association between cancer of the scrotum and mineral oils used in the textile industry and in the petroleum fuel industry in England is of long-standing documentation. The major risk of exposure today is in engineering or machining work, in which oils are used in connection with the cutting and milling of metals. Oils which have not been solvent-refined are more apt to induce carcinoma of the scrotum than oils which have been solvent-refined. The actual agent in cutting oils which causes carcinoma of the scrotum has not been identified, but the aromatic hydrocarbons may be implicated. Prolonged contact with oil and lack of personal cleanliness are predisposing factors for scrotum carcinoma. Age apparently does not influence risk of developing carcinoma of the scrotum; patients observed ranged in age from 8-91 yr. Working conditions, including heat, humidity, and high speed of the spindle to which the oil is applied as a lubricant, may also potentiate the carcinogenic effects of mineral oils. The incidence of carcinoma of the scrotum shows no signs of increasing; in Birmingham, England, 58 deaths from

carcinoma of the scrotum were recorded between 1958-1965 in a total population of 5 million. Carcinoma of the scrotum has a poor prognosis, with only 8 of 27 patients in 1 study surviving for 5 yr after initial treatment. Carcinoma of the scrotum ordinarily begins its course as a epithelioma which may later develop into a malignant lesion and at times invades the testicles. (36 references)

0860 ENZYMATIC REGULATION OF THE PLASTICITY OF THE ORGANISM AND CARCINOGENESIS. (Rus.)

Rapoport, I. A. (Inst. Chem. Physics Acad. Sci. USSR, Moscow), V. A. Parnes and D. M. Kevin. *Pat Fiziol Eksp Ter* 16(5):56-62, 1970.

The role of mutation and dedifferentiation in the pathogenesis of oncogenic processes is critically analysed. Reference is made to genetic studies with *Drosophila melanogaster* subjected to oncogenic RNA (Defective and nondefective strains of rous virus) and DNA (polyoma strains of the papova and human adenovirus type 12) viruses. None of these viruses produced genetic alterations under appropriate experimental conditions, thus contradicting results obtained by other authors. Therefore a mechanism of modification operating by means of a set of basic enzymes is suggested to be instrumental in neoplastic pathogenesis. This set of basic or operative enzymes would participate in the elaboration of products both inert and active in determining the concentrations of key substances such as nucleic acids and amino acids, and would control the initial stages of mitosis. Removal of such an operative enzyme from the metabolic framework in the adult organism may lead to uncontrolled cell proliferation. When the deviation due to the block of such an enzyme controlling cell division is of a limited nature, cell proliferation characteristic for benign neoplasia may occur. In cases in which a highly developed synthetic system loses an enzymatic factor controlling mitosis, malignant neoplastic growth may occur. In such case mobilization of energetic resources throughout the whole organism would take place. The continuity of the modification process would be maintained because the loss of such a controlling enzyme would not lead to cell death but to cell proliferation. (22 references)

0861 MALIGNANT TUMORS AMONG TWINS: A STUDY OF DIVERGENT VIEWS. (E.) Keith, L. (Chicago

Med. Sch., Ill.) and E. Brown. *Acta Genet Med Gemellol* 19(4):576-583, 1970.

The tendency of both members of dizygotic and monozygotic twins to develop cancer was investigated in a review of the literature of the subject. Most studies agreed that monozygotic twins have higher concordance rates for cancer than dizygotic twins. Especially high concordance rates have been reported for mammary cancer, uterine cancer, gonadal cancer, cancer in the eye, stomach cancer, and rectal cancer. Tumors, including type, site, and age of onset, appeared to affect monozygotic twins more than both members of a dizygotic twin pair. The

precise nature of the genetic effect on tumorigenesis in twins remained in doubt, although a mechanism for cancer concordance among monozygotic twins probably does exist. Confident conclusions about the development of cancer in twins is impeded by the diversity of patient groups, lack of standardization of collected data, and unreliability of classifications of mono- or dizygosity. CHEMICAL CARCINOGENESIS

0884 BRONCHIAL EPITHELIAL ALTERATIONS AND PULMONARY NEOPLASIA INDUCED BY OZONE. (E.)

Werthamer, S. (Methodist Hosp. Brooklyn, N. Y.), L. H. Schwarz and L. Soskind. *Path Microbiol* 35(1-3): 224-230, 1970.

The effect of ozone in air at sublethal concentrations on tumor resistant mice (male Swiss Webster) was studied with and without desmosterol treatment. One group of 100 mice was exposed to 4.5 ppm ozone in air for 2 hr every 3rd day for 75 days and received daily injections of desmosterol (0.2 mg). Another group of 120 animals were exposed to ozone on the same schedule as the first group and received daily injections of saline. A third group of 55 mice served as controls; 54 of these animals exhibited normal lung morphology at sacrifice, while one animal showed a mild focal hyperplasia of the bronchial epithelium. The experimental animals were randomly sacrificed from the 6th day on. Edema, congestion, scattered hemorrhage, bronchiectasis, emphysema, bronchitis, bronchiolitis, bronchopneumonia and microabscesses were the progressive changes observed with increasing numbers of exposure to ozone. Of the mice treated with ozone and desmosterol, 38% exhibited cellular changes, while 23% of the mice exposed to ozone and saline showed cellular changes. These changes ranged from hyperplasia, atypism, pyknotic and hyperchromatic nuclei to metaplasia and adenoma formation (8.0 and 6.6% for the ozone-desmosterol and ozone-saline-treated mice, resp.).

0885 PROSTATIC HYPERPLASIA AND NEOPLASIA IN FEMALE *PRAOMYS (MASTOMYS) NATALENSIS*. (E.)

Holland, J. M. (Northwestern U. Med. Sch., Chicago, Ill.). *J Nat Cancer Inst* 45(6):1229-1236, 1970.

Hyperplasia and neoplasia (associated with androgen injections) in the prostate of the female *Praomys (Mastomys) natalensis* were investigated. Proliferative changes in the prostate were found in 16 untreated controls; the changes became increasingly marked with age. In controls over 24-months-old, papillary hyperplasia was often seen, usually with granulosa cell proliferation of the ovary and proliferative changes of the endometrium. In all 18 *Mastomys* treated with testosterone injections (5 mg s.c. pellets of testosterone propionate every 3 wk or 10 mg i.m. of testosterone enanthate every 3 wk), the prostate became enlarged, and marked papillary hyperplasia developed with prolonged testosterone treatment. None of the androgen-treated *Mastomys* developed prostatic neoplasms. Ovine prolactin (8 mg pellet s.c. every 3 wk) administered with or without testosterone had no effect on prostate, body wt or other organs. Cystic dilatation was observed in 2 of 4 animals given diethylstilbestrol (12 mg pellet s.c. every 2 months). Solid adenomatous proliferation occurred in both of 2 untreated animals (26 months-old) with malignant prostatic changes and probable granulosa cell proliferation of the ovary.

0886 INFLUENCE OF HYPOTHYROIDISM ON THE DEVELOPMENT OF NEOPLASTIC PROCESSES IN RAT MAMMARY GLAND. (Rus.)

Skatkov, M. E. (Inst. Med. Genetics Acad. Med. Sci. USSR, Moscow) and V. I. Romanov. *Biull Exp Biol Med* 70(11):93-95, 1970.

The effect of 6-methylthiouracil (MTU) on the formation of mammary gland tumors was studied in 133 randombred female Wistar rats (120 g wt) divided into 3 experimental groups: 1) 42 rats were given 10 mg MTU in the diet daily for 2 yr; 2) 41 rats received the same dose daily with 30 day intervals for 2 yr; 3) 50 rats constituted the control group. An additional 9 rats were thyroidectomized and subjected to a count of gonadotropic (estrogen-secreting) cells in the adenohypophysis 8 days later. Continuous administration of MTU produced tumors in 17 rats, 8 of which had mammary gland adenocarcinoma, 1 had mammary gland hyperplasia, 3 had lung cancer, 2 had liver cancer and 1 had tumors of the ovaries. Intermittent administration of MTU produced tumors in 7 rats, 6 of which had cancer of the mammary gland, and 1 rat had liver sarcoma. The thyroidectomized rats exhibited approximately 9% levels of basophilic estrogen-secreting cells in the adenohypophysis and the intact control rats had 7% of such cells. The data seem to support the hypothesis that hyperestrinism is involved in development of hyperplasia and mammary gland cancer.

0887 THE INFLUENCE OF THYROACTIVE SUBSTANCES ON THE INDUCTION OF CERVICO-VAGINAL TUMORS IN INTACT AND CASTRATE RATS. (E.)

Cherry, C. P. (Strange-ways Res. Lab., Cambridge, England) and A. Glucksmann. *Brit J Cancer* 24(3):510-527, 1970.

The effect of L-thyroxine and of methylthiouracil on the development and incidence of cervico-vaginal tumors induced by 7,12-dimethylbenz(a)anthracene (DMBA) was investigated in intact and castrated rats. Rats were given L-thyroxine alone (20 µg in drinking water), with methylthiouracil (20 mg in drinking water) or, with stilbestrol (2 µg). DMBA (1%) was administered topically at weekly intervals. Methylthiouracil accelerated the rate of sarcoma induction in intact rats, while methylthiouracil with L-thyroxine delayed the appearance of tumors and reduced their numbers. Perinatal injections of either L-thyroxine or methylthiouracil in intact rats delayed the appearance of tumors. L-Thyroxine, methylthiouracil, or combinations of either agent with stilbestrol accelerated sarcoma production and increased the numbers of developing sarcomas in castrated rats. L-Thyroxine and methylthiouracil accelerated the development of tumors, but did not increase their numbers. Methylthiouracil accelerated and increased the numbers of epithelial tumors in both intact and castrates; this effect was reduced by stilbestrol treatment and L-thyroxine with methylthiouracil treatment in intact rats and was potentiated in castrates. Untreated castrates had higher incidences of sarcomas than untreated intact rats or intact rats given L-thyroxine and stilbestrol; the incidence of epithelial tumors was low in both untreated castrates and intact rats and greater in castrated than in intact rats given methylthiouracil with stilbestrol or L-thyroxine. Changes in the thyroid and the hypophysis induced by the 2 agents were not related to carcinogenesis. The differing responses of castrates and intact rats to tumor induction by the agents may be due to local factors.

0888 TUMOUR-PROMOTING PROPERTIES AND METABOLISM OF 5α-CHOLEST-6-ENE AND 5α-CHOLESTA-1,3,6-TRIENE. (E.)

De Kock, D. H. (Dept. Chem. U.

Stellenbosch, Union South Africa) and J. H. Barnardt. *S Afr Med J* 44(44):1274-1276, 1970.

The tumorigenic efficacy and the metabolism of 2 derivatives of cholesterol, 5 α -cholest-6-ene, and 5 α -cholesta-1,3,6-triene, were studied in mice. Male mice were injected s.c. with either of the 2 agents in combination with dibenz(a,h)anthracene (DBA) for varying periods of time. Of 12 mice given DBA (0.1 mg) alone, 3 developed tumors by 28 wk after injection, and 7 developed tumors by 50 wk postinjection. Of 10 mice given DBA (0.1 mg) and 5 α -cholest-6-ene (20 mg), all had developed tumors by 28 wk postinjection. The same results were obtained in mice given DBA and 5 α -cholesta-1,3,6-triene. Mice given only the cholesterol derivatives developed tumors in only 1 of 40 cases 50 wk after postinjection. Metabolic studies showed that 5 α -cholest-6-ene was metabolized to 5 α -cholestane-6 β , 7 α -diol, which was conjugated with glucuronic acid. The 5 α -cholesta-1,3,6-triene was converted to the glucuronide of 5 α -cholesta-1,3-dien-6 β , 7 α -diol. Enzymes responsible for this conversion were located in liver microsomes and required NADPH as a co-factor. The steroidal hydrocarbons may exert their tumorigenic effects by blocking the detoxification of DBA.

0889 EFFECT OF ALTERED HORMONAL STATES ON THE HISTOCHEMICAL DISTRIBUTION OF NUCLEIC ACIDS IN THE RAT PROSTATIC COMPLEX. (E.) Takkar, G. L. (Central Drug Res. Inst., Lucknow, India), V. P. Kamboj and A. B. Kar. *Indian J Exp Biol* 8(2): 63-67, 1970.

The effect of progesterone, estrogen, and altered thyroid status on the cytochemical distribution of DNA and RNA in the rat prostate was investigated. Rats were given 1 and 2.5 mg progesterone or 0.1 and 5 μ g estradiol by s.c. injections daily for 15 and 30 days. Progesterone evoked a progressive increase in intensity of the Feulgen staining reaction; the intense staining of the nuclei of epithelial and stromal cells appeared to be related to an increase in their chromatin content. Progesterone also increased both DNA and RNA contents of epithelial, stromal, vascular and mast cell elements. Cytoplasmic and nuclear RNA of the acinar epithelium increased after progesterone treatment more prominently in the ventral and lateral prostate. At low doses of estrogen, DNA and RNA in the nuclei, nucleoli, and cytoplasm of the acinar epithelia, stroma, blood vessels and mast cells were elevated. The higher dose of estrogen significantly inhibited prostatic function; the acinar epithelium was metaplastic and there was no secretion in the lumen. The stroma was hypertrophied and hyperplastic. DNA contents of epithelial chromatin, stromal and vascular elements increased markedly, while RNA levels increased only slightly. A combined dose of progesterone and estrogen produced results which were thought to suggest that the estrogen effect was antagonized by progesterone. In rats which had been thyroidectomized, prostatic function seemed to be stimulated; DNA content of chromatin of the epithelial cells was reduced in these rats.

0890 UPTAKE AND LOSS OF TRITIATED OESTRADIOL BY THE ADRENAL GLAND AND BY OESTROGEN-INDUCED ADRENOCORTICAL CARCINOMA IN THE RAT. (E.) Mobbs, B. G. (Dept. Urol., Queen's U., Kingston, Ontario, Canada). *J Endocr* 48(4):545-552, 1970.

The retention of estradiol by adrenals and tumors in rats with estrone-induced adrenocortical tumors and by adrenals in tumor-free rats was investigated. Female rats bearing estrone-induced tumors were used; 1 group carried tumors which grew only in rats bearing estrone pellets, and another group carried tumors which grew more quickly in rats with estrone pellets. Estrone-induced tumors were transplanted to ovariectomized rats without estrone pellets. All rats were given s.c. injections 16.7 μ C 6,7-³H-estradiol-17 β ; tritiated estradiol was also injected into non-tumor bearing rats (controls). In the adrenals of controls, uptake and loss of estradiol was rapid; there was no evidence of specific retention of the hormone by the adrenal. Mature ovariectomized non-tumor bearing rats retained 287.5 cpm of tritiated estradiol 150 min after injection, while retained estradiol for immature and mature but not ovariectomized rats at 150 min postinjection were 59 and 312 cpm, resp. Adrenals retained more estradiol than muscle in all cases, with ratios of estradiol retained by adrenals to estradiol retained by muscle ranging from 11:1-7:6. In rats bearing the tumor which grew only in the presence of estrogen, patterns of loss of estradiol were similar. At 23 min postinjection, the adrenals retained 147.9 cpm estradiol, while by 183 min postinjection, retention was down to 15.7 cpm. Retention of estradiol by the adrenocortical tumor was similar to retention by the adrenals. In rats bearing the tumor which grew more rapidly in the presence of estrone, retention of tritiated estradiol was at the level of 175 cpm in the adrenal (188 cpm in the tumor) at 36 min postinjection; by 179 min, 84 cpm of estradiol was retained in the adrenal (68 cpm in the tumor). In this tumor line, loss of estradiol from the host adrenal and the tumor was slower than that from muscle, while in the former tumor line there was no significant differences in the loss of estradiol by these systems. Loss of estradiol may have been determined more by the hormonal environment of the tissues than by estrogen receptors in the adrenal.

0891 EFFECT OF 17- β -ESTRADIOL AND TESTOSTERONE ON ARYL HYDROCARBON HYDROXYLASE ACTIVITY IN MOUSE TISSUES *IN VIVO* AND IN CELL CULTURE. (E.) Nebert, D. W. (Natl. Inst. Child Hlth., Human Develop., Natl. Inst. Hlth., Bethesda, Md.), L. L. Bausserman and R. R. Bates. *Int J Cancer* 6(3): 470-480, 1970.

The effect of 17- β -estradiol on the induction of the aryl hydrocarbon hydroxylase system by 3-methylcholanthrene (MC) or 7,12-dimethylbenz(a)-anthracene (DMBA) was studied *in vivo* in mouse liver and skin, in mouse fetal cell cultures, and in a cell-free *in vitro* system. Estradiol implants (20 mg, s.c.) did not significantly decrease the hepatic aryl hydrocarbon hydroxylase activity in either the Swiss mice (from 90 to 57 U/mg protein)

the C57BL/6N mice (from 88 to 71 U/mg protein); (2 mg, i.p.) produced a 2- to 4-fold induction of the hydroxylase system 48 hr after injection of DMBA (2 mg, i.p.) did not induce the enzyme. Estradiol did not significantly affect the basal enzyme level (0.013 and 0.040 U/mg protein) in the Swiss or C57BL/6N mice, resp., and did not alter the inducibility of hydroxylase activity by MC (16 µg, topical application) which produced a 4- to 15-fold increase in Swiss mice and a 15-fold increase in C57BL/6N mice, or by DMBA (16 µg, topical application) which produced 4-fold and 2-fold increases, resp., in the 2 strains of mice. In fetal cell cultures (uncomplicated by environmental stimuli) high concentrations of estradiol (1 mM) prevented hydroxylase induction by the polycyclic hydrocarbons; this suggested that physiologic levels of estradiol have little effect on hydroxylase induction and that the mechanism by which estradiol inhibits the skin tumorigenesis by DMBA is not related to this process. *In vitro* studies indicated that both estradiol and testosterone are competitive inhibitors of polycyclic hydrocarbon hydroxylation, estradiol being 10 times more effective than testosterone.

92 THYMIDINE INCORPORATION INTO HeLa CELLS INCREASED BY TUMOR-PRODUCING CROTON OIL FACTOR TPA. (E.) Freienstein, C. (German Cancer Res. Ctr., Heidelberg), S. Freienstein, G. Kreibich, Kinzel and R. Süß. *Naturwissenschaften* 57(12): 5-676, 1970.

HeLa cells treated with 13-0-tetradecanoyl-phorbol-13-acetate (TPA) were transferred into fresh medium, and thymidine incorporation after the medium change was followed to see if release of TPA inhibition would result in overshooting DNA synthesis due to release of a pre-S-phase block by TPA. Twenty-four old HeLa cell cultures were incubated for 24 hr with 10^{-4} - 10^{-10} M TPA in 0.5% dimethylsulfoxide; a TPA-free medium was then substituted and 1 hr thymidine pulses were introduced at 0, 2, 4 and 8 hr. The reaction was stopped at 0°C with trichloroacetic acid precipitation and thymidine incorporation was determined. The peak of overshooting DNA synthesis was a 2-fold increase in thymidine incorporation over control at 8 hr with 10^{-6} - 10^{-7} M TPA; at the 4 hr pulse, the peak thymidine incorporation was 130% of control at the same concentration. The *in vivo* tumor promoting effect of croton oil may be due to a blocking of DNA synthesis which on release results in overshooting DNA synthesis.

93 THE LEUKEMOGENIC ACTION OF PHORBOL. (E) Berenblum, I. (Weizmann Inst. Sci., Rehovot, Israel) and V. Loni. *Cancer Res* 30(11): 2744-2748, 1970.

The carcinogenic potency of phorbol was investigated in mice which were given phorbol alone and in conjunction with 7,12-dimethylbenz(a)anthracene (DMBA). Female mice were divided into 4 treatment groups: 1 group was given a single topical application of DMBA (0.25 mg) together with twice weekly i.p. injections of phorbol (totaling 8-12 mg);

another group was given phorbol without DMBA; a third group was given DMBA without phorbol; and the remaining group comprised the untreated controls. No skin tumors developed in any of the mice in any of the groups. Of the mice given DMBA and phorbol, 70% developed leukemia and 5% developed reticulum cell sarcoma after mean latencies of 118 days for sarcoma and 168 days for leukemia. In the group given phorbol alone, 57% of the mice developed leukemia and 29% developed reticulum cell sarcoma after mean latencies of 196 days for leukemia and 207 days for sarcomas. Mice receiving DMBA alone developed no leukemia, but 4% developed sarcomas, while 6% of the untreated controls developed leukemia and 20% developed sarcomas. Most of the induced tumors were of lymphoblastic origin and nonthymic. Most leukemias showed advanced infiltration of affected organs.

0894 STUDIES ON THE IMMUNE RESPONSES OF BALB/c MICE DURING TUMOR INDUCTION BY MINERAL OIL. (E.) Kripke, M. L. (Hebrew U. Hadassah Med. Sch., Jerusalem, Israel) and D. W. Weiss. *Int J Cancer* 6(3):422-430, 1970.

The effects of mineral oil injections on the immunological responses of BALB/c mice, which are susceptible to the oncogenic effects of oil, and of C57Bl mice, which are resistant, were investigated. Male mice of the 2 strains were given 3 i.p. injections of 0.5 ml of bayol 55 or primol 355, followed by tests of neutralization of bacteriophage T₂, graft-versus-host reaction tests, tests of syngeneic tumor growth, and tumor immunogenicity tests. Although BALB/c mice showed evidence of preneoplastic development between 18-105 days after injection, C57Bl mice showed no signs of neoplastic development. Only a slight decrease was noted in the primary antibody responses against T₂ phage cells of oil-treated BALB/c mice after a single injection. However, there was a marked reduction in the antibody response in these mice after 2 or 3 treatments; no significant reduction was seen in anti-T₂ titers in oil-treated C57Bl mice at any point. In graft-host reaction studies spleen cells from oil-treated and normal mice were injected into newborn (BALB/c x C57Bl)_{F1} hybrids. The mean spleen index of hybrids given cells from BALB/c mice treated twice with oil was lower than that of hybrids given cells from BALB/c donors not treated with oil. In hybrids given cells from C57Bl mice a similar reaction was seen; however, after the 3rd injection of spleen cells, the mean index in these recipients was higher than that of recipients of cells from C57Bl mice not treated with oil. In tests of syngeneic tumor growth, oil-treated mice were given injections of 5×10^3 cells of the oil-induced plasmacytoma MO-8; oil-treated mice were more susceptible to tumor cells than untreated mice. C57Bl mice treated with oil were highly resistant to tumor implantation. Immunogenicity studies on tumors induced by mineral oil in BALB/c mice showed that tumors induced in these mice by oil-injection possessed tumor-associated antigenicity. The results appeared to suggest that immunological depression in the susceptible BALB/c mice may contribute to the development of progressive neoplasia induced by mineral oil.

- 0895 HIGH INCIDENCE OF PULMONARY TUMORS IN dd MICE BY A SINGLE INJECTION OF CYCASIN. (E.) Hirono, I. (Gifu U., Sch. Med., Japan) and C. Shibuya. *Gann* 61(5):403-407, 1970.

The induction of lung and liver tumors in mice treated with cycasin (8-D-glucosyloxyazoxymethane) was investigated. Newborn mice were given a s.c. injection of 0.5 mg cycasin/g body wt (group I) or of 1.0 mg cycasin/g body wt (group II). Of 39 mice in group I, 17 survived more than 150 days after injection, and 88% of the survivors developed lung adenomas and 64% developed liver adenomas and hepatomas. Lung tumors developed from 5-14 months after injection, and liver tumors developed from 7-14 months after injection. Of 115 mice in group II, 57 survived for 16 days after injection; of these 57, 22 showed neurological disorders. Of the 35 mice in group II surviving beyond 150 days post-injection, 83% developed lung tumors (5 carcinomas) and 37% developed liver cell adenomas and hepatomas. Other tumors occurring in group II were reticulum cell neoplasm and leukemia (1 case of each). Most lung carcinomas invaded the bronchial lumen or peripulmonary tissues.

- 0896 ARE THERE RENAL ADENOCARCINOMA-FREE POPULATIONS OF LEOPARD FROGS? (E.) McKinnell, R. G. (Dept. Zool., U. Minnesota, Minneapolis) and D. P. Duplantier. *Cancer Res* 30(11):2730-2735, 1970.

Two populations of leopard frog (*Rana pipiens*) were found to be free of renal adenocarcinomas and preliminary experiments in tumor promotion were performed on frogs from these groups. A group of 466 frogs collected in Louisiana were found to be tumor-free on autopsy; 2 of 12 frogs developed renal adenocarcinomas when injected in the embryo phase with cell-free extracts of a renal tumor. Of 980 frogs collected in North Dakota, 932 were autopsied and found to be tumor-free. Two renal adenocarcinomas developed in frogs from this group when they were kept at room temperature (20-22°) for 8 mo. It was suggested that the development of renal tumors in *Rana pipiens* is associated with pesticide use in agricultural areas.

- 0897 CARCINOGENICITY OF THE HERBICIDE MONURON. (Rus.) Rubenchik, B. L. (Sci. Res. Inst. Food Hyg., Kiev, U.S.S.R.), N. E. Botsman and G. P. Gorban. *Vop Onkol* 16(10):51-53, 1970.

The carcinogenicity of monuron herbicide [3-(p-chlorophenyl)-1,1-dimethylurea] was studied in 100 randombred white male rats, in 50 white randombred and 45 C57Bl male and female mice. The rats were given daily 450 mg/kg monuron in their diet for 18 months; the mice received 6 mg of monuron in milk p.o. once a wk for 15 wk. The total experimental period for rats lasted 27 months and 13 months for mice. The first tumor in rats appeared on the 18th wk of the experiment (microcellular lung cancer) in 1 rat; other cancers developed between 68-118 wk of experimentation. The first tumor in randombred mice appeared at 16 wk and after 4 wk in the C57Bl mice. Malignancy occurred in 15 rats, in 13 ran-

dombred and in 7 C57Bl mice; the liver and the lung appeared to be the main target organs. The malignant liver hepatomas exhibited a hepatocellular cancer structure with highly polymorphic cells, giant cells with hyperchromic nuclei, atypical mitoses and micronecroses. The lung tumors originated in the alveolar cells or in the bronchial epithelial lining, and the gastric tumors originated in the glandular epithelium. Tumor incidence was 46.5% in rats, and no tumors were found in controls. The incidence of both malignant and benign neoplasm was 56.5% in randombred, 26.9% in C57Bl mice, and 3.9% in C57Bl control mice.

- 0898 THE INDUCTION OF SARCOMA OF THE SKIN IN THE ALBINO RAT BY CADMIUM CHLORIDE. (Ger.) Knorre, D. (Dist. Hosp. St. Georg, Leipzig, Germany). *Arch Geschwulstforsch* 36(2):119-126, 1970.

Induction of a s.c. sarcoma by CdCl₂ (0.003 mM/100 g body wt, single dose) was studied in 80 male Wistar rats 12 wk-old at the beginning of the experiment. Spindle cell sarcoma developed at the injection site in 6 out of 45 surviving animals after 7-18 month latency periods. One rat sacrificed 248 days after injection exhibited disseminated peritoneal metastases; the other 5 rats had occasional regional lymph node metastases. No spontaneous skin or testicular tumors were noticed among the 20 control rats during the 23-month observation period.

- 0899 EFFECTS OF THE COADMINISTRATION OF THIAMINE ON THE INCIDENCE OF URINARY BLADDER CARCINOMAS IN RATS FED BRACKEN FERN. (E.) Pamukcu, A. M. (Coll. Vet. Med., U. Ankara, Turkey), S. Yalciner, J. M. Price and G. T. Bryan. *Cancer Res* 30(11):2671-2674, 1970.

The development of bladder and intestinal tumors in rats maintained on a diet containing bracken fern (*Pteris aquilina*) supplemented in some cases with thiamine was investigated. Male and female albino rats ingested daily a 25 g diet of about 1/3 bracken fern, or the same diet was given with thiamine (2 mg of thiamine hydrochloride weekly, s.c.). Most rats given either of the 2 test diets lived more than 6 months. Intestinal tumors were first detected in males and females on the experimental diets at the age of 6 months; bladder tumors were first detected in males and females at the ages of 9 and 7 months, resp. All of the rats that were given bracken fern alone or bracken fern and thiamine and survived more than 6 months developed intestinal tumors. Two of the 26 rats given bracken fern developed bladder tumors; 54 of the 90 rats given bracken fern and thiamine developed bladder tumors. Sixty nine percent of the females and 53% of the males in the bracken fern and thiamine group developed bladder tumors. The gross and microscopic morphological characteristics of bracken fern-induced tumors were identical to bladder tumors induced by the carcinogen N-[4-(5-nitro-2-furyl)-2-thiazolyl] formamide. No intestinal or bladder

ors developed in control rats receiving neither bracken fern nor thiamine. The increased incidence of bladder tumors in rats fed bracken fern and thiamine may have been due to an alteration of the absorption, distribution, metabolism, or excretion of the bracken fern carcinogen brought about by thiamine.

0 PROPERTIES OF THE SARCOMAS INDUCED BY FERRIDEXTRAN SPOFA IN INBRED RAT STRAIN AVN: THE OBSERVATION OF H-1^a AND B 1 ANTIGENITY OF FEDEX-AVN/3 TUMOR FOLLOWING LONG TERM *IN VITRO* CULTIVATION. (E.) Krenova, D. (Fac. Gen. Med., Charles U., Prague, Czechoslovakia), V. Kren and O. Krk. *Neoplasma* 17(5):505-512, 1970.

in vitro antigenicity of the FEDEX-AVN/3 tumor induced by Ferridextran Spofa) was analyzed by testing the H-1^a histocompatibility antigen and the thymocyte B 1 antigen by isoimmunization of allelic rat strains WP and LEW by tumor cells. Subsequent testing of the antisera was done against a panel of rat erythrocyte types, and the absorbency capacity of the tumor cells from *in vitro* cultivation was compared to that of syngeneic peritoneal cells). Both the H-1^a antigenic complex and B 1 erythrocyte antigen of the FEDEX-AVN/3 tumor were found to be fully preserved during the long term *in vitro* cultivation.

1 *IN VITRO* ASSAY OF THE STIMULATORY EFFECT OF BONE MARROW CELL PROLIFERATION OF SERA OBTAINED AFTER CHLORAMBUCIL TREATMENT. (E.) Niskanen, E. (2nd Dept. Path., U. Helsinki, Finland), T. Rönkä and E. Kivilaakso. *Acta Path Microbiol Scand* 78(5):589-594, 1970.

The effect of sera obtained from rats at various intervals (2, 5, 6, 8 and 9 days) after a single dose of chlorambucil (12 mg/kg, i.p.) on ³H-thymidine and ³H-adenine uptake in normal bone marrow cells was studied *in vitro*. ³H-Adenine incorporation (reflecting mainly the effect on RNA synthesis) by sera taken 9 days after treatment was increased by 29.2%. Sera taken after 5, 6, and 8 days increased the incorporation of ³H-thymidine by 19.1%, 20.3%, and 53.8%, resp.), while after 9 days only a slight stimulation (5.7%) was observed; these results paralleled the changes in the number of granulocytes found in the bone marrow (approximately 30% of the control value after 2 days and gradually rising to the control value by 9 days after chlorambucil treatment). Bone marrow cell proliferation may be due to the initial reduction of the number of cells.

2 FATE AND METABOLISM OF SOME MUTAGENIC ALKYLATING AGENTS IN THE MOUSE: I. ETHYL METHANESULFONATE AND METHYL METHANESULFONATE AT SUBLETHAL DOSE IN HYBRID MALES. (E.) Cumming, R. B. (Oak Ridge Natl. Lab., Tenn.) and M. F. Walton. *Int J Rad Biol* 10(4):365-377, 1970.

The metabolic fate of ethyl methanesulfonate (EMS, 0 mg/kg, i.p.) and methyl methanesulfonate (MMS,

150 mg/kg, i.p.) with a ¹⁴C-alkyl label (1 µC/g) in (101 x C3H)F₁ hybrid male mice was determined by measuring the radioactivity in various tissues, in the blood, urine, and exhaled ¹⁴C-carbon dioxide at various time periods ranging from 15 min to 24 hr after injection. Both EMS and MMS were rapidly distributed throughout the body, but MMS showed an uneven distribution (cpm/mg wet weight) with the tissues active in detoxification having higher levels of radioactivity (3200-13000) and peripheral tissues having lower levels (1200-2000). In circulating blood, EMS activities ranged from 200 at 15 min after injection to 650 at 4 hr after injection and MMS activity remained constant at 400-500 during the first 8 hr before declining. MMS-treated animals excreted 34% of the radioactivity in the urine during the first 24 hr while EMS-treated animals excreted only 15%; however, the EMS-treated animals excreted approximately 60% of the injected activity as ¹⁴C-carbon dioxide during the first 12.5 hr compared to 27% excreted by the MMS-treated animals.

0903 CHEMICAL MUTAGENESIS IN MAMMALS: THE CHINESE HAMSTER BONE MARROW AS AN *IN VIVO* TEST SYSTEM: HEMATOLOGICAL FINDINGS AFTER TREATMENT WITH TRENIMON. (Ger.) Boller, K. (U. Chil. Clin. Zurich, Switzerland) and W. Schmid. *Humangenetik* 11(1):35-54, 1970.

Trenimon-induced chromosomal damage was studied in the bone marrow of Chinese hamsters. The trenimon was given i.p. in saline in doses of 0.031-2 mg/kg. The bone marrow smears were taken from the femurs and analyzed qualitatively and quantitatively for Jolly bodies and leukocyte bodies; heart blood was used for hematological analysis. The quantitative changes in the bone marrow following trenimon administration were not conclusive. Qualitative changes revealed many pathological nuclear forms and a definite dose dependency. With high doses, cells with fragmented structureless nuclei were seen. The most striking changes appeared from 6-12 hr after 2 administrations in a 24-hr interval. If the percentage of pathological nuclei could be considered as a criterion of chromosome damage, this method offers a technique for toxicological screening of chromosome damaging agents and for mutagenicity testing.

0904 STUDIES IN RATS ON IMMUNOSUPPRESSIVE PROPERTIES OF CYTOSTATICS WITH SPECIAL CONSIDERATION OF CARCINOGENIC EFFECT. (Ger.) Scherf, H. R. (German Cancer Res. Inst., Heidelberg), C. Krüger and C. Karsten. *Arzneimittelforschung* 20(10):1467-1470, 1970.

The relationship between the immunosuppressive and the carcinogenic effects of the cytostatic compounds used in cancer chemotherapy was studied in Sprague-Dawley rats. Fifteen agents used in cancer therapy were tested by means of the hemagglutination test, the plaque test (according to Jerne), and quantitative immunodiffusion to discover their immunosuppressive action. The immune reaction following the single administration of a cytostatic drug (40% of the LD₅₀)

was manifested by a decrease in hemagglutinin titer only after methotrexate, 6-mercaptopurine, and endoxan. The immune reaction after the 7% of LD₅₀ injection once weekly over 14 wk, resulted in a decrease in the hemagglutinin titer in animals treated with 5-fluorouracil. Trenimon only decreased this titer after the first administration and then returned to normal. Results show that although the antimetabolites showed marked immunosuppressive properties, they do not appear to be carcinogenic. Other examples show that no correlation exists between the carcinogenic and immunosuppressive effects, under the conditions reported here.

- 0905 CANCEROGENIC ALKYLATING SUBSTANCES: IV. 1,3-PROPANE SULTONE AND 1,4-BUTANE SULTONE. (Ger.) Druckrey, H. (Max Planck Inst. Immunobiol., Freiburg, Germany), H. Kruse, R. Preussmann, S. Ivankovic, C. Landschütz and J. Gimmy. *Z Krebsforsch* 75(1):69-84, 1970.

Observations of local sarcomas following subcutaneous injection of dimethyl sulfate in rats led to the investigation of numerous alkylating substances for carcinogenic properties. When 1,3-propane sultone was tested in 12 rats by weekly s.c. injections of 30 or 15 mg/kg in 1% olive oil, local necroses appeared after several weeks; treatment was discontinued until these were healed. After 21 weeks and total doses of 390 or 210 mg/kg, histological examination revealed marked infiltration of the tumor into the cutaneous and muscular tissue, and one rat showed multiple pulmonary metastases. One animal, on the lower dose, developed an abdominal tumor; after a paraplegia of the hind quarters and a paralysis of the bladder, it was found at autopsy, that a neurogenic tumor developed in the lumbar area. The experiment was repeated with oral administration (8.5% of LD₅₀) by means of gavage, in 12 rats. In spite of the high activity of the 1,3-propane sultone and its rapid disturbance of the gastric function, a definite absorption could be demonstrated. The observation of 2 tumors in the cerebral region points to a certain neurotropy. I.V. administration of 1,3-propane sultone (40 mg/kg) weekly to 10 rats for 16 weeks resulted in the development of sarcomas in 3 animals with one mixed tumor in the brain of one animal. With a single i.v. injection, 9 of 32 animals treated with the carcinogen showed malignant tumors. The transplacental experiments yielded 7 tumors in 39 offspring after a single dose administered to the mothers. An analog, 1,4-butane sultone produced a markedly different reaction than 1,3-propane sultone in an acute experiment in rats. Administration by any route was followed immediately by a hypersensitivity that affected otherwise quiet animals with periodic jumping and stretch cramps; death resulted from clonic muscle twitching and spasms of the throat musculature. The results of s.c., i.v., or p.o. administration of 1,4-butane sultone, showed a carcinogenic effect less marked than that of propane sultone.

- 0906 EXPERIMENTAL STUDIES ON CARCINOGENIC EFFECTS OF ANTI-CANCER CHEMOTHERAPEUTICS AND IMMUNOSUPPRESSIVES. (Ger.) Schmähel, D. (German

Cancer Res. Ctr., Heidelberg) and H. Osswald. *Arzneimittelforschung* 20(10):1461-1467, 1970.

The carcinogenic action of the most important cancer chemotherapeutic agents was investigated. The study was carried out in 1284 male rats of the BR-46 line and 100 female mice of the NMRI-line; the male rats were more sensitive to the drugs tested than the female rats. The preparations tested were: alkylants, antimetabolites, naturally occurring compounds, peroxide forming compounds and antibiotics. To represent long term therapy, the animals were given 7% of the LD₅₀ (i.v. or by stomach tube) over 52 weeks, and for the short term study, the drugs were injected only 5 times at 2 week intervals. These animals died at a relatively young age compared to other carcinogen-treated animals, probably due to the frequent occurrence of infections. The carcinogenic effects of the alkylants (myleran, mitomen, endoxan, degranol, trenimon, thio-tepa) which were seen were different degrees of lymphatic and myelogenous leukemias, lymphosarcomas, pheochromocytomas, etc., in 11-30% of the treated animals. No carcinogenic effects were observed as a result of antimetabolite or natural product treatment. Of the antibiotics only sanamycin (actinomycin C) was tested in 22 rats and revealed 1 paramyeloblast leukemia and 1 intraabdominal carcinoma, 4 benign tumors and 3 thymomas and an adrenocortical adenoma. X-ray irradiation showed similar carcinogenic effects to those of alkylants. In the experiments for short term effects, vinblastine was found to be noncarcinogenic, whereas endoxan and mitomycin showed marked carcinogenic effects.

- 0907 NEOPLASMS OF URINARY BLADDERS OF HAMSTERS TREATED WITH 2-ACETYLAMINOFLUORENE AND INDOLE. (E.) Oyasu, R. (Northwestern U. Med. Sch., Chicago, Ill.), H. Sumie and H. E. Burg. *J Nat Cancer Inst* 45(5):853-860, 1970.

The induction of bladder tumors by injections of 2-acetylaminofluorene (AAF) together with dietary administration of indole was investigated in newborn male hamsters. Animals were given i.p. injections of AAF (5 mg/100 g body wt) 3 times/wk for 3 wk; at 3 wk of age, they were fed a synthetic diet containing 0.06% AAF and 1.6% indole. Of 26 hamsters surviving the experimental course, all developed transitional cell carcinoma in the bladder after 11 months; tumors were invasive in 24 cases. All animals showed diffuse or focal hyperplasia of the mucosa. Tumors often grew in multiple foci in the early stages, invading the basement membrane and the lamina propria. About 2/3 of the hamsters with bladder tumors had foci of acute and chronic inflammation. Although the livers of treated animals were often slightly decreased in size, no hepatomas were found. However, bile duct proliferation and fibrosis were present in varying degrees of severity. Other lesions less frequently observed included retroperitoneal histiocytoma, pancreatic adenocarcinoma, and papillary adenocarcinoma of the gallbladder.

- 0908 EFFECTS OF ADRENALECTOMY AND BILE DUCT LIGATION ON THE URINARY EXCRETION OF METABOLITES OF 2-ACETAMIDOFLUORENE BY MALE WEANLING RATS. (E.) Lotlikar, P. D. (Temple U. Sch. Med.,

Philadelphia, Pa.) and M. Gruenstein. *Biochem J* (5):921-923, 1970.

effects of bile-duct ligation and adrenalectomy on the urinary excretion of metabolites of the carcinogen 2-acetamidofluorene in rats were investigated. Male weanling rats were either adrenalectomized, subjected to bile-duct ligation or both, after which they were given an i.p. injection of 2-acetamidofluorene (3 mg/100 g body wt). Urine samples were then assayed for the presence of *N*-hydroxy-2-acetamidofluorene (*N*-hydroxy-AAF) and other metabolites of the carcinogen. Rats undergoing bile-duct ligation followed by 2-acetamidofluorene injection showed more than a 2-fold increase in excreted *N*-hydroxy-AAF compared to intact controls (controls, 1.55%; ligated animals, 2.03%). Excretion of 3-, 5-, and 7-hydroxy-AAF was also increased in bile duct-ligated rats. Bile-duct ligation of adrenalectomized rats resulted in a smaller increase in *N*-hydroxy-AAF excretion (2.03%). *N*-hydroxy-AAF excretion in the adrenalectomized and ligated group was decreased to about 58% of that in the ligated group.

9 REACTIVE PHOSPHATE ESTER OF THE CARCINOGEN 2-(*N*-HYDROXY)ACETAMIDOFLOURENE. (E.) Likar, P. D. (Temple U. Sch. Med., Philadelphia, Pa.) and M. B. Wasserman. *Biochem J* 120(3):661-665, 1970.

Interaction of *N*-acetoxyacetamidofluorene (*N*-acetoxy-AAF) with inorganic phosphate to form *N*-phosphate and ring phosphate esters is described. *N*-acetoxy-AAF was incubated with phosphate buffer at 25°C to give a water-soluble product with absorption peaks at 303, 290, and 280 nm, but *N*-hydroxy-AAF did not undergo this reaction. Methionine reacted with the phosphate-dependent polar fluorene derivative to give a product with the same R_f value (0.35-0.44) as synthetic 3-methylmercapto-AAF. The *N*-acetoxy-AAF phosphate derivative similarly reacted with guanosine to give a product with R_f value of 0.8-0.94, which probably was *N*-(guanosyl-8-yl)-AAF. *N*-acetoxy-AAF derivative was very labile and hydrolyzed by both acid and alkaline phosphatases with liberation of P_i and ether-soluble fluorene derivatives. These results suggested that the compound AAF-*N*-phosphate which may also decompose or rearrange to form an unreactive ring phosphate of AAF. It appears that AAF-*N*-phosphate might be formed *in vivo* by interaction of *N*-acetoxy-AAF and P_i or by enzymic conversion of *N*-hydroxy-AAF with ATP and P_i . This compound might be the ultimate carcinogenic metabolite of *N*-acetoxy-AAF, but attempts to detect phosphate metabolites of the parent compound in urine of rats treated with *N*-acetoxy-AAF were unsuccessful.

10 OVARIAN INFLUENCE ON PULMONARY CARCINOGENESIS BY HYDRAZINE SULFATE IN BALB/c/Cb/Se Mice. (E.) Biancifiiori, C. (Perugia U. Med. Sch., Italy). *J Nat Cancer Inst* 45(5):965-970, 1970.

Development of pulmonary carcinomas induced by hydrazine sulfate (HS) in gonadectomized mice,

and breeding mice, and intact virgin female mice was investigated. Mice in the various experimental groups were given daily doses of 1.13 mg HS by stomach tube beginning at 8 wk-of-age; 150 doses were given. Ninety percent of intact virgin mice developed pulmonary tumors; the average number of tumors developed by a mouse was 3. Breeders developed tumors in all cases, 14 tumors/mouse being the mean. Gonadectomized mice developed tumors in 60% of cases, and the average number of tumors/mouse was 5. The tumors developed by intact virgins and gonadectomized mice were most often adenomas (96%), with some carcinomas (3-4%). Breeders developed 47% carcinomas and 52% adenomas. No local spread or metastases were observed in tumors developed by gonadectomized mice, but both conditions occurred in 60% of breeders; there was metastasis to the adrenals in 2 mice. Liver tumors (hepatocarcinomas) were observed in 28% of the treated mice and ovarian tumors were observed in 24% of breeders. Apparently increased ovarian hormone production was associated with the greater biological and morphological malignancy of the tumors developed by breeding mice.

0911 THE DETERMINATION OF 3-HYDROXYANTHRANILIC ACID IN BLOOD SERUM IN THE EARLY STAGES OF EXPERIMENTAL CARCINOGENESIS. (Rus.) Korosteleva, T. A. (N. N. Petrov Sci. Res. Inst. Oncol., Leningrad, USSR) and A. T. Zasyпка. *Vop Onkol* 16(10):47-50, 1970.

A method for the immunological determination of 3-hydroxyanthranilic acid in animal sera during the early stages of benzidine carcinogenesis is presented. Five groups of C3HA mice (consisting of 10-15 animals each) and 5 groups of randombred rats (consisting of 5-7 animals each) were given benzidine (0.1 mg/g wt and 0.025 mg/g wt, resp.) in their daily diet for 4, 15, 30, 60 and 100 days. 3-Hydroxyanthranilic acid (3-HOAA) was determined as a serum haptene by means of an agar precipitin reaction against 3-HOAA antibody-containing rabbit sera obtained by i.p. immunization of rabbits with synthetic 3-HOAA azoproteins. A specific precipitin band in the experimental animal sera occurred after 4 (40% of mice and rats), 30 (30% of mice and rats) and 60 (in 50% of the animals) and 100 benzidine administrations (100% positivity); no such reaction was noticed in sera of animals treated 15 times and of control animals. The absence of the 3-HOAA-specific band in sera of the animals at the stage of 15 administrations may be due to an immunological removal of 3-HOAA or to compensatory mechanisms leading to a temporary recovery of tryptophan metabolism. Alterations in tryptophan metabolism seem to occur prior to or at the very early stages of carcinogenesis.

0912 DETECTION OF POLYCYCLIC AROMATIC HYDROCARBONS IN HUMAN CARCINOMATOUS TISSUE. (Ger.) Wagner, K. H. (Giessen Univ., Germany) I. Siddiqi and E. Wagner-Hering. *Naturwissenschaften* 57(11):547, 1970.

Tissue samples from human bronchial carcinoma were found to contain as much as 32 µg/100 g tissue of

3,4-benzpyrene, while samples from gastric carcinoma and rectal carcinoma contained 3,4-benzfluoranthene in amounts of 23 $\mu\text{g}/100\text{ g}$ and 13 $\mu\text{g}/100\text{ g}$ tissue, resp. Besides these compounds other unidentified fluorescent compounds were detected. These compounds seem to have accumulated in the gastrointestinal tract over a long time period via food ingestion. The presence of 3,4-benzfluoranthene in bronchial carcinoma tissues implicates its presence in the environmental air or in cigarette smoke. A certain critical level of polycyclic hydrocarbons apparently has to be accumulated prior to the beginning of the metastatic process.

- 0913 CARCINOGEN AND MICROSOMAL MEMBRANE INTER-ACTION: CHANGES IN MEMBRANE DENSITY AND ABILITY TO BIND NUCLEIC ACIDS. (E.) Kubinski, H. (U. Wisconsin Sch. Med., Madison) and C. B. Kasper. *Science* 171(3967):201-203, 1971.

The changes in the density of the nucleic acid-membrane complex formed through the binding of DNA (from *Escherichia coli*) or of synthetic copolymer polyribocytidylic-polyriboguanilyc acid (polyC-polyG) to microsomal membrane from rat liver were determined on cesium chloride gradients in the presence of various carcinogenic chemicals. Membrane incubated with polyC-polyG before centrifugation in cesium chloride peaked at a density of 1.18, while membrane incubated with DNA peaked at both 1.18 and 1.22. Incubation with 2-acetylaminofluorene (2 mg/ml) yielded DNA associated with a major peak at a density 1.22 and 2 minor peaks at 1.18 and 1.13, and polyC-polyG was associated with peaks at 1.15, 1.17, and 1.22. Incubation with N-acetoxy-2-acetylaminofluorene (2 mg/ml) yielded a DNA peak at 1.25 and a polyC-polyG peak at 1.19, while incubation with N-hydroxy-2-acetylaminofluorene (2 mg/ml) yielded complexes of densities between 1.19 and 1.25. With β -propiolactone (4mg/ml) a single peak was observed at 1.16, and with 3-methyl-1-p-tolyltriazine (2 mg/ml) a small peak was observed at 1.16 but most of the material was found at a higher density (1.18). Chemical carcinogens may act by interfering with the chemistry and biological activity of cellular membranes.

- 0914 AFLATOXIN B₁: CYTOTOXIC MODE OF ACTION EVALUATED BY MAMMALIAN CELL CULTURES. (E.)

Scaife, J. F. (Euratom Joint Res. Ctr., Ispra, Varese, Italy). *FEBS Letters* 12(3):143-147, 1971

The mode of action of aflatoxin B₁ was examined by observing the inhibition of RNA synthesis in various animal cells treated with aflatoxin B₁. Human kidney cells, HeLa S₃ cells, Chang liver cells, and 3T3 mouse cells were cultured in monolayers and exposed to aflatoxin B₁. The toxin rapidly inhibited RNA synthesis in rat liver cells, slices, or liver *in vivo*; after 1-3 hr of incubation of these tissues with aflatoxin, DNA synthesis was depressed to 44, 59, and 26% of control DNA synthesis rates, resp., in adult rat liver cells, liver slices, and liver *in vivo*. Inhibition of RNA synthesis in human kidney T cells, HeLa S₃ cells, and Chang liver

cells was more delayed. Ten $\mu\text{g}/\text{ml}$ of aflatoxin incubated with cells for 30 min gave 98 and 88%, resp., of control DNA synthesis for kidney T cells and Chang liver cells. Exposure of synchronized cell cultures to aflatoxin for up to 14 hr showed that the cells were retarded in passage through the S-phase, and that their DNA synthesis rates were decreased. Mitosis was also inhibited, apparently as a function of the amount of time cells exposed to aflatoxin took to complete the S-phase. Liver cells apparently converted aflatoxin B₁ to a more potent cytotoxin which was able to affect cells which were ordinarily not susceptible, a hypothesis which can explain the susceptibility of the liver to carcinogenesis induced by aflatoxin B₁.

- 0915 NUTRITION AND AFLATOXIN CARCINOGENESIS. (E.) Rogers, A. E. (Dept. Nutr. Food Sci., Massachusetts Inst. Technol., Cambridge) and P. M. Newberne. *Nature* 229(5279):62-63, 1970.

Interactions between nutritionally induced liver disease and carcinoma induced by aflatoxin were investigated. Diets marginal in lipotropes were associated with differences in the response of rats to aflatoxin. Male rats were maintained on a lipotrope-deficient diet or on a control diet; for acute toxicity studies rats were given a single i.p. dose of aflatoxin B₁ (7 mg/kg). The lipotrope deficiency protected all rats against doses of aflatoxin which were lethal to 60-100% of rats on the control diet. Rats on the lipotrope-deficient diet and a carcinogenic dose of aflatoxin B₁ (15 daily doses of 25 μg each) showed focal areas of hyperplastic abnormal hepatocytes which were thought to be preneoplastic. A close correlation was also observed between the early appearance of liver cell carcinomas and the lipotrope-deficient diet. Carcinomas had appeared in 25% of rats on the lipotrope-deficient diet 6 months after aflatoxin treatment, and in none of the rats on the normal diet at this point. The lipotrope-deficient diet decreased aminopyrine demethylase, *p*-nitroanisole demethylase, and benzpyrene hydroxylase activities relative to the values for these enzymes in rats on the control diet. The findings may indicate that aflatoxin B₁ is not itself toxic, but must be metabolized to a toxic product, a process which normally-nourished livers accomplish readily but which lipotrope-poor livers do not; the high tumor incidence in areas in which there is malnutrition and aflatoxin B₁ food contamination tend to support this hypothesis.

- 0916 EFFECTS OF AFLATOXIN ON SOME MARKER ENZYMES OF LYSOSOMES. (E.) Tung, H. T. (Dept. Poultry Sci., North Carolina St. U., Raleigh), W. E. Donaldson and P. B. Hamilton. *Biochem Biophys Acta* 222(3):665-667, 1970.

The effect of dietary aflatoxin on acid phosphatase and β -glucuronidase, 2 marker enzymes for lysosomes, was investigated in chickens. Male chicks were given graded doses of aflatoxin in their diet of commercial feed, and enzyme activity was assayed in sections of liver and breast muscle. Aflatoxin increased both enzyme activities, even at low doses.

phosphatase activity in muscle was 1.0 and $U \times 10^{-2}/mg$ protein, resp., at aflatoxin doses 0 and 2.5 $\mu g/g$. In liver, β -glucuronidase activity was at 1.0 and 2.4 $U \times 10^{-2}/mg$ protein, resp., at aflatoxin doses of 0 and 2.5 $\mu g/g$. Time courses of 48 hr were noticed between introduction of aflatoxin and the onset of significant increases in liver acid phosphatases, which were paralleled by increases in capillary fragility.

7 THE FORMATION OF AFLATOXINS B_{2a} AND G_{2a} AND THEIR DEGRADATION PRODUCTS DURING *IN VITRO* DETOXIFICATION OF AFLATOXIN BY LIVERS OF CERTAIN AVIAN AND MAMMALIAN SPECIES. (E.)

Person, D. S. P. (Central Vetr. Lab., Minist. of Agric., Fisheries, Food, Weybridge, Surrey, England) and B. A. Roberts. *Food Cosmet Toxicol* 8(5):527-538, 1970.

Aflatoxin G₁ was found to be metabolized as rapidly as aflatoxin B₁ in liver microsome preparations from chick, duckling, guinea pig and mice. Metabolic products of aflatoxins B₁ and G₁ included unidentified metabolites which were spectrally similar to the aflatoxin hemiacetals, B_{2a} and G_{2a}. Methanol extracts of liver incubations showed peak absorption at about 400 nm at pH 6.5 or greater, and the absorption was intensified when strong ammonia solution was added. The aflatoxin hemiacetals B_{2a} and G_{2a} were unstable in dilute phosphate-buffered protein solution (pH 7.4); in this reaction, the hemiacetals were first bound to protein, and then degraded to form yellow substances. Cysteine added in amounts of 5 mM inhibited the degradation of the aflatoxin hemiacetals; when cysteine was added to a standard incubation mixture, 50% of the aflatoxin was metabolized by chick liver fractions was spectrophotometrically identified as its hemiacetal. The toxicity of the aflatoxin hemiacetals may result from their instability in protein solutions.

8 EFFECT OF AFLATOXIN B₁ ON THE *IN VITRO* INCORPORATION OF ¹⁴C-ACETATE INTO HUMAN SKIN LIPIDS. (E.) Black, H. S. (VA Hosp., Houston, Texas), J. D. Smith, B. J. Austin, and E. W. Schkolb. *Experientia* 26(12):1292-1293, 1970.

The effect of aflatoxin B₁ on the incorporation of ¹⁴C-labeled acetate into human skin lipids was investigated *in vitro*. Fresh human skin preparations were made from male Caucasians, and treated with $1 \mu g$ aflatoxin B₁ and $1 \mu C$ of ¹⁴C-acetate. Aflatoxin B₁ inhibited the incorporation of labeled acetate into the total lipid, phospholipid, free sterol, and neutral fat fractions of human skin. Total lipid incorporation of ¹⁴C-acetate in aflatoxin-treated preparations was at 23.55 cpm $\times 10^{-3}/100 mg$ protein wt, as compared to 40.02 cpm $\times 10^{-3}/100 mg$ for untreated control preparations. Phospholipid incorporation of labeled acetate decreased from 3.69 $\times 10^{-3}/\mu g P_i$ in controls to 2.49 cpm in aflatoxin-treated preparations.

19 EFFECT OF PHENOBARBITAL PRETREATMENT ON THE ABILITY OF AFLATOXIN B₁ TO INHIBIT

RIBONUCLEIC ACID SYNTHESIS IN RAT LIVER. (E.) Gumbmann, M. R. (Western Reg. Res. Lab., Albany, Calif.) and S. N. Williams. *Biochem Pharmacol* 19(11):2861-2866, 1970.

The effect of pretreatment with phenobarbital on nucleic acid synthesis inhibition by aflatoxin B₁ in rat liver was investigated. Male rats were given daily i.p. injections of sodium phenobarbital (75 mg/kg) for 5 days; shortly before death, rats were given a single i.p. injection of aflatoxin B₁ (1.5 mg/kg). Either phenobarbital or aflatoxin was withheld in controls. Without phenobarbital, a 28.3% reduction in nuclear RNA synthesis was seen in 4.5 hr in aflatoxin-treated rats, while with phenobarbital the nuclear RNA reduction was 8.6%. Cellular RNA/DNA ratios in aflatoxin-treated rats were decreased by 4%, while in rats pretreated with phenobarbital, the reduction of nuclear RNA/DNA was 3.1%. The inhibition of the uptake of ¹⁴C-labeled orotic acid by nuclear RNA by aflatoxin was 65.1%, but only 36.5% in rats pretreated with phenobarbital. Phenobarbital treatment alone produced a marked increase in liver wt in rats without changing the DNA level, suggesting that liver growth resulted primarily from cellular enlargement as opposed to cellular proliferation.

0920 BIOCHEMICAL CHANGES IN LIVER DUE TO AFLATOXIN. (E.) Shankaran, P. (Vallabh-bhai Patel Chest Inst., U. Delhi, India), R. Shankaran, H. G. Raj and T. A. Venkatasubramanian. *Brit J Exp Path* 51(5):487-491, 1970.

The effect of aflatoxin treatment on lipid content, glycogen content, protein content and enzyme activity in the liver was investigated in mice. Male mice were given i.p. injections of aflatoxin B₁ at a dose of 1 mg/kg body wt, and assays were performed 2 and 8 hr later. No change was observed in the liver content of glycogen, lipid or protein in treated mice 2 hr after injection of aflatoxin. Significant decreases were found in the activities of aconitase, malate dehydrogenase in the supernatant fraction of liver preparations and ATPase; significant increases were found in isocitrate dehydrogenase, fumarase, and malate dehydrogenase activity in the particulate fraction. Eight hr after injection with aflatoxin, aconitase activity was recorded as 107 U/mg protein in treated mice and 160 U/mg in controls; similar figures for malate dehydrogenase were 337 U/g protein for aflatoxin-treated mice and 376 U/g protein for controls. Fumarase activity in control mice after 8 hr was recorded as 5525 U/g protein and 3282 U/g for controls; isocitrate dehydrogenase activity in controls was 24 U/g after 8 hr and in ATPase treated mice, 31.9 U/g. In the case of aconitase, fumarase and ATPase, changes obtained 8 hr after aflatoxin treatment were the opposite of those obtained 2 hr after treatment. Mitochondrial injury by aflatoxin and altered protein synthesis may account for these results.

0921 BINDING OF DIMETHYLAMINOAZOBENZENE METABOLITES TO DNA AND PROTEINS: I. *IN VITRO*

STUDIES ON A MICROSOMAL DEPENDENT SYSTEM. (E.)

Meunier, M. (Inst. Res. Sci. Cancer, Villejuif, France) and J. Chauveau. *Int J Cancer* 6(3):463-469, 1970.

The binding of dimethylaminoazobenzene (DAB) metabolites to DNA and proteins was investigated *in vitro*. DAB (aniline ring- $U^{14}C$) was incubated with NADPH, purified thymus DNA and rat liver microsomes. In this system, DAB that was bound to DNA measured 41.3 μ moles DAB/g DNA; DAB bound to microsomal proteins measured 453 μ moles DAB/g protein. When microsomes were omitted from the incubation system, or replaced by boiled microsomes or by enzymatically inactive protein, DNA labeling was drastically reduced (2.1 μ moles DAB/g DNA for a microsome free system). This finding appeared to indicate that a metabolic activation was required for binding to occur. NADPH was necessary for binding of DAB, for in systems in which NADPH was left out, bound DAB measured 0.7 μ moles/g DNA and 10 μ moles/g protein. Doubling the amount of microsomes in the incubation medium approximately doubled the binding of DAB to DNA. The amount of DAB metabolites increased with time of incubation, the increase being linear for the first 15 min, then dropping off for the next 30 min. Binding of DAB also depended on the pH of the medium; an 8-fold increase in binding was found when the pH was 7.4 compared to the value found with pH 6 (41 and 5 μ moles bound metabolites of DAB/g DNA, resp.). These findings suggested that the process of activation of DAB binding was enzymatic in nature. The kinetics of the binding of DAB metabolites to proteins were similar to the kinetics of the binding of DAB metabolites to DNA. After treatment of rats with 3-methylcholanthrene for 2 days, there was a 10-fold increase in the DNA binding and a 6-fold increase in protein binding, compared to control rat microsomes. Binding of DAB metabolites to DNA and protein was thought to be of a covalent nature.

0922 ENZYMIC ACTIVITY AND MORPHOLOGICAL ALTERATIONS IN LIVERS OF RATS FED ON *p*-DAB (DIMETHYLAMINOAZOBENZENE). (E.) Cerny, E. (Med. Fac., J. E. Purkyne U., Brno, Czechoslovakia) and F. Papousek. *Scripta Med* 43(3-4):143-150, 1970.

The effect of *p*-dimethylaminoazobenzene (DAB) treatment on liver enzyme activity and morphology was investigated in rats. Livers of rats fed 0.06% DAB in the diet showed increasing dystrophic alterations progressing in time to oligocellular necrosis, an increase in lymphocytes, increasing cholangiolar hyperplasia, and deposition of iron pigment in Kupfer cells. One cholangiocarcinoma and 2 adenomas were observed. Acid phosphatase activity was increased in the treated animals (17-49%) compared to untreated controls (14%). Nonspecific esterase with alpha-naphthylacetate activity was generally higher in treated rats than in controls, normal values being 16% and experimental values ranging from less than 16% in 3 of 50 cases to a maximum of 46%. Nonspecific esterase with naphthol AS-acetate activity was higher in treated rats than in controls. Succinic acid de-

hydrogenase activity was also higher in treated rats than in controls, mean values for controls being 3.8% and values for treated animals exceeding this level in 49 of the 50 cases, with an experimental maximum of 10.8%.

0923 AZO-DYE BINDING TO PROTEINS AND DETOXICATION OF *p*-DIMETHYLAMINOAZOBENZENE IN MOUSE AND HAMSTER LIVER. (E.) Decloitre, F. (Inst. Res. Sci. Cancer, Villejuif, France) and M. Meunier. *Int J Cancer* 6(1):481-487, 1970.

Protein-bound azodyes, azoreductase, and NADPH-cytochrome *c* reductase in the livers of rodents maintained on a regimen of *p*-dimethylaminoazobenzene (DAB) were investigated. Male mice of the IC and C3H strains and male hamsters were fed DAB (60 mg/kg body wt) in their diets. IC mice showed no histological abnormalities in their livers until 6 months after the start of DAB feeding, at which time glycogen and fat deposits together with an inflammatory reaction were seen. These abnormalities were noted in C3H mice 6 wk after the beginning of DAB feeding. By the third month livers of C3H mice showed nodules of increasing size and density, progressing to carcinoma in some cases. One yr after the beginning of DAB feeding hamster livers showed little or no abnormal effects. C3H mice exhibited azodye binding to proteins far in excess of that shown by IC mice or hamsters. Three wk after the beginning of treatment, C3H mice showed azodye binding at a maximum level of 18 μ mole bound azodye/100 mg protein. Three-wk azodye binding values for IC mice and hamsters were 5 and 2.5 μ moles, resp. Proteins from hamsters and IC mice were bound to azodyes at comparable levels throughout the course of the experiment. Azoreductase activity was 5 times greater in control IC mice than in C3H mice; in hamsters, activity was intermediate. The 3 kinds of control animals had similar NADPH-cytochrome *c* reductase activity. Both azoreductase and NADPH-cytochrome *c* reductase increased with DAB feeding in IC mice; increases were 60% at 1 wk and 40% at 2 wk of DAB feeding. DAB feeding decreased azoreductase after 3-6 months in C3H mice, while NADPH-cytochrome *c* reductase was increased by 65% in this strain. DAB had no marked effect on enzyme levels in hamsters. The sensitivity of C3H mice to DAB toxicity might be related to their low levels of azoreductase activity, while high azoreductase activity in IC mice probably allows adequate detoxication of DAB to prevent its toxic effects.

0924 CARCINOGENIC ACTIVITY OF DIBENZOTHIOPHENE: ANALOGS OF *p*-DIMETHYLAMINOAZOBENZENE. (E.) Brown, E. V. (Dept. Chem., U. Kentucky, Lexington) and R. Isbrandt. *J Med Chem* 14(1):84-85, 1970.

Four isomers of *p*-dimethylaminophenylazodibenzothiophene were prepared and tested for carcinogenicity in the rat liver. While *p*-dimethylaminoazobenzene in 0.06% concentrations produced hepatocarcinomas in 7 of 10 rats at 4 months and in 9 of 10 rats at 6 months, the 4 isomers of *p*-dimethylaminophenylazodibenzothiophene produced no tumors when tested at the same concentrations for 6 months.

5 ADRENOCORTICAL LIPID HYPERPLASIA INDUCED IN RATS BY ANILINE: A HISTOLOGIC AND ELECTRON MICROSCOPIC STUDY. (E.) Kovacs, K. (Inst. Exp. Surg., U. Montreal, Quebec, Canada), J. Blascheck, E. Yeghiayan, S. Hatakeyama and C. Dell. *Amer J Path* 62(1):17-34, 1971.

adrenal cortex of rats injected with aniline (5 mg, s.c.) was subjected to electron microscopic studies. Seven to 14 days after injection of aniline, adrenals were enlarged, and the cortices were markedly broader. Changes in the adrenals of treated rats were more pronounced in the inner cortical layers than in the zona glomerulosa. The numbers of lysosomes in aniline treated rats were increased, and the mitochondrial matrices were more conspicuous and showed swelling and rarefaction. Mitochondrial protrusions were noted in some mitochondria. Abundant lipid droplets were found in both treated and untreated adrenals; no marked changes were observed in the vasculature, nuclei, Golgi complexes, collagen particles, or free ribosomes of aniline-treated rats. The most striking change was seen in the adrenal cortex of rats given aniline for 7 or 14 days; extensive accumulation of lipid droplets occurred in the cytoplasm. In some cells lipid droplets coalesced and enlarged to the extent that they occupied the whole cytoplasm, masking the nuclei and distending the cells. Long, rectangular or needle-like crystals were seen in the cytoplasm of some treated cells. More variation in shape and size of mitochondria, enlargement of the endoplasmic reticulum and prominent Golgi apparatus were seen in the adrenals after 7 or 14 days of aniline treatment. In general, the alterations observed in adrenals of rats treated with aniline resembled those seen in certain types of congenital human adrenal hyperplasia. Aniline may inhibit cellular steroidogenesis, leading to decreased hormone secretion and perhaps adrenal enlargement.

6 BIOLOGICAL EFFECTS OF 7,12-DIMETHYLBENZ(a)ANTHRACENE (DMBA). ABSORPTION OF DMBA AT GASTROINTESTINAL LEVEL IN MICE. (Fr.) Gentil, J. (Inst. Res. Sci. Cancer, Villejuif, France), C. L. and I. Chouroulinkov. *Bull Cancer* 57(2):269-274, 1970.

The distribution of 7,12-dimethylbenz(a)anthracene (DMBA) at the gastrointestinal tract levels was investigated in ICI mice after p.o. and i.v. administration of the tritium-labeled compound. DMBA-³H dissolved in olive oil was given p.o. (0.6 ml containing 100 µC per mouse) to 2 groups of mice on an empty stomach; one group consisted of pretreated mice which had been receiving unlabeled DMBA (1 mg p.o. daily) for 4 months, and the second group consisted of untreated mice. Another group of mice pretreated with DMBA and untreated) were administered a suspension of DMBA-³H in colloidal aqueous solution (0.5 ml containing 100 µC) in the caudal vein. The mice were sacrificed 6, 15, 18, 24, 48 and 72 hr after the treatment. A 10-20-fold higher label accumulation in the cardiac stomach region with respect to the other organs of the gastrointestinal tract was noticed in both pretreated

and normal mice 1 hr following oral administration of the hydrocarbon. High levels of label were also noticed in the small intestine 6 hr and in the mesentery 15-19 hr after oral treatment in the pretreated mice, which were similar to the levels found throughout the other segments of the intestinal tract in the latter. I.V. administered DMBA-³H led to the appearance of homogeneous radioactivity within both the glandular and cardiac stomach, small intestine and mesentery with no appreciable differences between pretreated and untreated animals. The largest amounts of DMBA were bound by the liver and kidney which are the main routes of its excretion after i.v. administration. A correlation between the difficulty of induction of cancer in the glandular stomach by p.o. DMBA administration and its transportability through cell membranes at this level was confirmed. The changes observed at the mesenteric level in pretreated mice following p.o. DMBA-³H administration confirmed the hypothesis that DMBA induces mesenteric tumors.

0927 EFFECTS OF PROLACTIN OR GROWTH HORMONE ON GROWTH OF CARCINOGEN-INDUCED MAMMARY TUMORS OF ADRENO-OVARIETOMIZED RATS. (E.) Nagasawa, H. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan) and R. Yanai. *Int J Cancer* 6(3):488-495, 1970.

The effect of prolactin and bovine growth hormone (GH) on the growth of 7,12-dimethylbenz(a)anthracene (DMBA)-induced mammary tumors was investigated. Immature female rats were given i.v. injections of 5 mg of DMBA, and when palpable mammary tumors had developed, rats were adreno-ovariectomized. Adreno-ovariectomized animals were injected twice daily i.v. with GH (1.5 mg) or prolactin (1.25 or 2.5 mg). Prior to hormone injection, there was little difference in the body wt of the rats; however, adreno-ovariectomized rats treated with GH showed a 23% increase in body wt, while those treated with 2.5 mg prolactin showed an 18% decrease. The number of tumors which developed in intact controls, adreno-ovariectomized and prolactin-treated (1.25 mg prolactin), and adreno-ovariectomized and prolactin-treated (2.5 mg prolactin) rats increased by 33, 124 and 239%, resp. The number of tumors which developed in adreno-ovariectomized controls and in adreno-ovariectomized and GH-treated rats decreased gradually. Prolactin treatment in both doses increased the size of mammary tumors markedly; tumors occurring in rats given 2.5 mg of prolactin continued to increase in size after the growth of tumors developed by rats given 1.25 mg prolactin had leveled off. GH had no effect on tumor growth; however, it accelerated the growth of normal mammary glands. Administration of 2.5 mg prolactin beginning 20 days after adreno-ovariectomy increased the number and size of regressed mammary tumors to pre-operative levels, but the 1.25 mg dose had no effect. Apparently, prolactin is the hormone mainly responsible for the growth of tumors induced by DMBA.

0928 FURTHER STUDIES OF THE EFFECT OF BONE MARROW CELLS ON CHEMICALLY INDUCED

LYMPHOMA IN C57BL/6 MICE. (E.) Chen, L. (Weizmann Inst. Sci., Rehovoth, Israel). *Brit J Cancer* 24(3): 554-560, 1970.

The effect of syngeneic bone marrow cell inoculation on chemically induced lymphoma was investigated in C57BL/6 mice. Young mice were given intragastric doses of 7,12-dimethylbenz(a)anthracene (DMBA) followed by 15×10^6 syngeneic bone marrow cells; other groups of mice were exposed to whole body X-irradiation (170 rads) followed by syngeneic bone marrow cells. DMBA treatment alone induced lymphomas in 52% of mice, while DMBA plus bone marrow cells induced lymphomas in 45% of cases. X-irradiation alone effected a 77% incidence of tumors, while irradiated mice which were given bone marrow cells or bone marrow cells plus DMBA developed lymphomas in 28 and 33% of the cases, resp. The thymus glands of mice treated as described were weighed in order to test the regenerative effect of bone marrow cells on the DMBA-injured thymus; it appeared that bone marrow cells did not hasten thymic regeneration. Bone marrow cells from DMBA-treated and untreated mice were tested for their ability to prevent radiation leukemogenesis, with the result that lymphoma development was prevented in 33% of mice given marrow cells from treated mice and 28% of mice given marrow cells from untreated mice. Bone marrow cells from DMBA-treated mice were no more effective than bone marrow cells from untreated mice in repairing radiation damage to the thymus, or in preventing the lethal action of high doses of irradiation. Neither did marrow cells succeed in restoring antibody formation to Shigella which was depressed by DMBA. Apparently, bone marrow cells inhibit a specific stage in radiation leukemogenesis, but are not involved with the leukemia process as such.

0929 EFFECTS OF RESERPINE ON DEVELOPMENT OF 7,12-DIMETHYLBENZANTHRACENE INDUCED MAMMARY TUMORS IN FEMALE RATS. (E.) Welsch, C. W. (Dept. Anat., Michigan St. U., East Lansing) and J. Meites. *Experientia* 26(10):1133-1134, 1970.

The effect of reserpine, reportedly an enhancer of mammary development, on mammary tumors induced by 7,12-dimethylbenz(a)anthracene (DMBA) was studied in immature female rats. Rats were given doses of either 10 μ g or 100 μ g reserpine/100 g body wt (s.c. injections) followed by a single i.v. injection of 5 mg DMBA. Another group was treated with reserpine in comparable amounts after the appearance of DMBA-induced mammary tumors. Reserpine treatment at 100 μ g doses reduced the incidence of DMBA-induced mammary tumors, with rats given 0 or 10 μ g reserpine developing tumors in 100% of cases and rats given 100 μ g reserpine developing tumors in 81% of cases. Average numbers of tumors/rat were decreased by reserpine treatment, averages for control, 10 μ g-treated, and 100 μ g-treated animals being 10.9, 7.5 and 3.3, resp. The wt of induced tumors was also lower in reserpine-treated rats. Mean latency of tumor development was similar in control rats and rats given 10 μ g reserpine (68-70 days); however, 100 μ g doses of reserpine increased

mean latency to 98 days. Growth and development of mammary tumors was significantly increased by treatment with 10 μ g of reserpine after onset of tumor development. However, reserpine failed significantly to affect tumor development in ovariectomized female rats.

0930 GROWTH INHIBITION OF RAT MAMMARY CARCINOMA AND ENDOCRINE CHANGES PRODUCED BY 2-Br- α -ERGOCRYPTINE, A SUPPRESSOR OF LACTATION AND NIDATION. (E.) Heuson, J. C. (J. Bordet Inst., Brussels, Belgium), C. Waelbroeck-Van Gaver and N. Legros. *Europ J Cancer* 6(5):353-356, 1970.

The effect of injecting 2-Br- α -ergocryptine (CB-154) into rats bearing tumors induced by 7,12-dimethylbenz(a)anthracene was investigated. Female rats were administered the carcinogen at 50 days of age; when mammary carcinomas had developed, they were administered s.c. injections of CB-154 daily in doses of 3 mg/kg for 3 wk. In the CB-154-treated group of rats, 18 of 27 tumors decreased in size while 9 tumors increased or remained unchanged; in this group only 16 new tumors developed. In the untreated control group, 8 tumors decreased in size, 19 increased or remained unchanged, and 32 tumors were newly formed. CB-154 also produced accumulation of a large number of corpora lutea and shortened the estrus cycle; the corpora lutea seemed inactive with respect to the secretion of progestational compounds and did not undergo normal involution. Interference of CB-154 with prolactin secretion is probably responsible for the effect of the drug on tumor growth and on endocrine functions.

0931 REPLICATION OF DNA AFTER BINDING OF THE CARCINOGEN 7,12-DIMETHYLBENZ[a]ANTHRACENE. (E.) Bates, R. R. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), S. D. A. Eaton, D. L. Morgan and S. H. Yuspa. *J Nat Cancer Inst* 45(6):1223-1228, 1970.

This study was designed to determine the ability of DNA in cell cultures of mouse skin to replicate after binding of 7,12-dimethylbenz(a)anthracene- 3 H (3 H-DMBA). Full thickness skin from term fetuses of mice of the NIH General Purpose Swiss strain was dissociated with 0.5% trypsin followed by exposure to pancreatic deoxyribonuclease I. After growth and reseeded, cells were incubated in medium containing 7,12-dimethylbenz(a)anthracene- 3 H and thymine-free medium containing 5-bromodeoxyuridine in varying sequence. After suitable exposure to the media, DNA was extracted, fractionated by gradient centrifugation and absorption measured at 260 nm; half as much DMBA was bound to DNA which had replicated after removal of DMBA from the culture medium as was bound to the DNA which had not replicated during this period. Replication of carcinogen-bound DNA may lead to altered base-pairing, giving rise to inherited mutation although repair mechanisms can allow for generation of normal cells.

0932 SUPPRESSION OF CARCINOGEN-INDUCED RAT MAMMARY TUMOR FORMATION BY ACTINOMYCIN D.

Anderson, K. M., (Dept. Path. Chem., U. Toronto, Toronto, Ontario, Canada) and J. A. Kellen. *Experientia* 26(9):1000-1001, 1970.

Effect of actinomycin D on tumorigenesis induced by 7,12-dimethylbenz(a)anthracene was investigated in rats. Rats were injected with 7,12-dimethylbenzanthracene (DMBA) and 25 µg of actinomycin D, the injection of the latter agent either preceding or following the injection of DMBA by 20 min. Rats given the carcinogen alone developed palpable mammary tumors in 100% of cases from 50-200 days after treatment, while 25% of the rats given carcinogen followed by actinomycin D developed tumors, and 28% of the rats given actinomycin D prior to carcinogen administration developed tumors. Rats given carcinogen followed 1 min later by actinomycin D developed tumors in 22% of cases. No apparent effect on the estrous cycle of treated rats was observed, which indicates that neither the pituitary, the testes, nor the ovaries are affected by actinomycin D.

3 STRUCTURE AND ACTIVITY IN CHEMICAL CARCINOGENESIS: REACTIVITY AND CARCINOGENICITY OF 7-BROMOMETHYLBENZ[a]ANTHRACENE AND 7-METHYLBENZ-12-METHYLBENZ[a]ANTHRACENE. (E.) Dipple, (Roy. Cancer Hosp., London, England) and T. A. De. *Europ J Cancer* 6(5):417-423, 1970.

Comparison of the carcinogenic activities of two 7-methylbenz(a)anthracenes with those of their parent hydrocarbons in groups of 10 CB-Hooded adult male rats is reported. Under the conditions of the test (25 µg s.c.), the cumulative number of rats with sarcoma at the injection site using 7-methylbenz(a)anthracene was 1 at 6 months, 2 at 9 months, 2 at 12 months; using 7,12-dimethylbenz(a)anthracene tumor incidence was 8 at 6 months, 9 at 9 months and 9 at 12 months; with 7-bromomethyl-12-methylbenz(a)anthracene 6 tumors were found at 6 months, 9 at 9 months, and 10 at 12 months. The carcinogenicity of 7-bromomethyl-12-methylbenz(a)anthracene was comparable to its parent, 7,12-dimethylbenz(a)anthracene and considerably greater than its hydrolysis product, 7-hydroxymethyl-12-methylbenz(a)anthracene; 7-bromomethylbenz(a)anthracene was less active than its parent, 7-methylbenzanthracene. A direct relationship appeared to exist between chemical reactivity and carcinogenic potential.

4 THE BINDING OF BENZ[a]ANTHRACENE TO REPLICATING AND NONREPLICATING DNA IN CELL CULTURE. (E.) Yuspa, S. H. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and R. R. Bates. *Proc Soc Exp Biol Med* 135(3):732-734, 1970.

The binding capacity of ³H-benz(a)anthracene (BA) was tested in fetal mouse skin cell cultures utilizing 5-bromodeoxyuridine, and the replicating DNA was separated from non-replicating DNA after 20 hr incubation by density gradient ultracentrifugation. ³H-BA was found to be bound to both newly synthesized DNA (at which incorporated 5-bromodeoxyuridine) and to

non-replicating DNA, which indicated that synthesis is not a requirement for binding. However, BA, a weak carcinogen, was found to bind very poorly to DNA compared to 7,12-dimethylbenz(a)anthracene, a strong carcinogen.

0935 THE POSSIBLE ROLE OF RIBOFLAVIN DEFICIENCY IN EPITHELIAL NEOPLASIA: II. EFFECT ON SKIN TUMOR DEVELOPMENT. (E.) Wynder, E. L. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.) and P. C. Chan. *Cancer* 26(6):1221-1224, 1970.

The effect of riboflavin deficiency on the development of epithelial neoplasms was investigated in mice. Female mice were fed a vitamin B₂-deficient diet for a wk, then returned to a normal diet shortly before being given a topical dose of 75 µg of 7,12-dimethylbenz(a)anthracene (DMBA). Vitamin-deficient mice developed tumors in greater numbers than normally-fed controls given DMBA; by 17 wk after DMBA treatment, control mice had developed tumors in 55% of cases, while mice given DMBA from 7 days before the reinstitution of the normal diet to 2 days after the recovery from riboflavin deficiency had developed tumors in 80-90% of cases. All tumors were papillomas. Mice given DMBA 7 days before recovery from vitamin deficiency developed an average 4.7 tumors/mouse, while mice in other vitamin-deficient groups developed 3.0-3.5 tumors/mouse, and controls developed an average of 1.6 tumors/mouse. Accelerated tumor development occurred in mice given DMBA after 5 wk of deficient diet and then painted with 1% croton oil twice weekly after being put back on a normal diet. In mice fed a normal diet injected with riboflavin before DMBA treatment the tumor yield did not differ from that of the controls, suggesting that riboflavin treatment itself does not counteract the initiating effect of DMBA, nor the tumor-promoting effect of croton oil.

0936 ELIMINATION AND METABOLISM OF BENZO(a)-PYRENE AFTER INTRATRACHEAL INJECTION. (Ger.) Dehnen, W. (Med. Inst. Air Pollut. Silicose Res., U. Düsseldorf, Germany), R. Tomingas, E. G. Beck, N. Manojlovic and M. Kirch. *Z Krebsforsch* 75(1):14-22, 1970.

Benzo(a)pyrene (BP) elimination from the lung through the blood stream following intratracheal injection was studied in Wistar rats. BP determinations were made by perfusion of the lung for 1 hr with saline and compared to untreated rat lungs in which recovery studies had been done with 5-16 µg of BP. The metabolic degradation of BP was studied in treated and untreated rat lung homogenates, lung microsomal fractions, liver microsomal fractions and in *in vitro* guinea pig alveolar and peritoneal macrophage cultures. Approximately 2-5% of the added BP (5-16 µg) was recovered with perfusion within 1 hr from the lungs of the untreated rats. The treated rats had 200 µg of BP in the lung 24 hr after intratracheal administration, and 1% was eluted following 1 hr of saline perfusion. The blood levels of BP following intratracheal adminis-

tration of 200 μg were 0.2 μg /total blood volume (considered to be 50 ml/1000 g body wt) 1 hr following administration and reached a peak value of 0.55 μg at 3 hr; then it returned to 0.2 μg 72 hr after intratracheal injection; when BP was given p.o. (100 μg and 1000 μg) the blood levels of BP were 0.033 and 0.035, resp. Lung homogenate and microsomal fractions from intracheally treated animals prepared 2.5 hr after BP administration and incubated with 2 μg of BP degraded 0.009 μg /mg protein and 0.025 μg /mg protein, resp; liver microsomes metabolized 0.3 μg /mg protein. Alveolar macrophage cultures incubated with BP and examined by fluorescence microscopy revealed a diffuse intracytoplasmic distribution of BP. The metabolism of 2.87×10^{-3} μg BP by 10^6 cells within 20 hr indicated the extent of the metabolizing capacity of guinea pig alveolar macrophages. The elimination of the inhaled BP from the lung appears to depend mainly on the functional condition of the alveolar macrophages.

- 0937 COMPARATIVE STUDIES ON THE INTERACTION OF BENZO[a]PYRENE WITH CELLS DERIVED FROM POIKILOthermic AND HOMEOTHERMIC VERTEBRATES: I. METABOLISM OF BENZO[a]PYRENE. (E.) Diamond, L. (Wistar Inst. Anat. Biol., Philadelphia, Pa.) and H. F. Clark. *J Nat Cancer Inst* 45(5):1005-1011, 1970.

The capacity to metabolize the carcinogen benzo(a)pyrene (BP) and the cytotoxicity of BP were investigated in warm- and cold-blooded organisms, including birds, rodents, reptiles, amphibians and fish. Monolayer tissue cultures from these organisms were inoculated with ^3H -BP, and after 24 hr of incubation with the carcinogen the amount of BP metabolized/cell was calculated from the ^3H -BP equivalents in the aqueous phase of a chloroform:methanol:water extraction mixture. Mouse embryo and hamster embryo cells were highly efficient in the metabolism of BP, showing values of 0.51 and 1.12 μg ^3H -BP degraded/ 10^7 cells/24 hr, resp. Other highly efficient cells were box turtle heart cells (1.30 μg), tokay gecko lung (1.41 μg), and American toad embryo (2.42 μg). Cells which metabolized from 0.25-0.50 μg ^3H -BP/ 10^7 cells/24 hr included bluegill fry, leopard frog embryo, and green iguana liver. Cell cultures metabolizing less than 0.25 μg of ^3H -BP included chick embryo, Russell's viper spleen and lung, and side-necked turtle heart. The most efficient metabolizer of BP was American toad embryo (2.42 μg). BP showed cytotoxicity only in cell cultures which were highly efficient metabolizers of the carcinogen.

- 0938 ISOLATION OF A BENZ[a]PYRENE-THYMINE PHOTOADDUCT FROM DNA HYDROLYZED AFTER IRRADIATION AT 365 nm IN THE PRESENCE OF BENZ[a]PYRENE. (E.) Antonello, C. (Inst. Chem. Pharm., U. Padua, Italy) and F. Carlassare. *Z Naturforsch* 256(11):1269-1271, 1970.

The products of the photoreaction between benzo(a)pyrene and DNA (from salmon sperm) which occurs af-

ter irradiation at 365 nm were isolated by precipitation and hydrolysis of the macromolecule followed by column (alumina) and thin layer (cellulose powder MN 300) chromatography. Four fluorescent substances with almost identical UV absorption spectra were separated on the chromatoplates with R_f values (distance of substance from origin/distance of benzo(a)pyrene from origin) of 2.35 (fraction A), 2.95 (fraction B), 3.17 (C), and 4.10 (D), resp. Fraction C was identical (migration compared in various chromatographic systems) with the photoadduct benzo(a)pyrene-thymine obtained after irradiation in previous studies. This photoadduct was obtained with a molecular ratio of 1:7000 with respect to the nucleotides present in the DNA used.

- 0939 INDUCTION OF BENZO[a]PYRENE HYDROXYLASE ACTIVITY IN RAT SKIN. (E.) Schleder, E. (Pharmacol. Inst., Free U. Berlin, Germany) and A. H. Conney. *Life Sci* 9(22):1295-1303, 1970.

The effect of 3-methylcholanthrene (MC) treatment on benzo(a)pyrene hydroxylase activity was investigated in the rat. Five mg of 3-methylcholanthrene was applied topically to the dorsal skin of female rats once daily for 1-3 days. Benzo(a)pyrene hydroxylase activity was assayed and expressed as the formation of 3-hydroxybenzo(a)pyrene. Benzo(a)pyrene hydroxylase activity in untreated controls was uniformly low (5 ng of 3-hydroxybenzo(a)pyrene formed/mg protein/20 min.). A single application of MC increased benzo(a)pyrene hydroxylase activity to 45 ng/mg/20 min in 24 hr. By 2 days after treatment, benzo(a)pyrene hydroxylase had increased to 70 ng/mg/20 min, but thereafter values declined slightly. Benzo(a)pyrene hydroxylase was increased only slightly when the amount of benzo(a)pyrene added to the reaction was increased from 50 μg to 200 μg .

- 0940 EFFECT OF INOCULA OF BENZO[a]PYRENE-TREATED SARCOMA CELLS ON GROWTH OF PRIMARY TUMORS IN RATS. (E.) Hall, J. G. (Chester Beatty Res. Inst., Sutton, Surrey, England) and D. J. Glover. *J Nat Cancer Inst* 45(6):1163-1168, 1970

The effect of inoculating tumor-bearing rats with tumor cells treated with benzo(a)pyrene on the growth of primary tumors was investigated. Fibrosarcomas were induced in rats with s.c. pellets of benzo(a)pyrene, and most of the tumor tissue was removed surgically when the tumors were 1.5-2.5 cm in diameter. Excised tumor cells were exposed to 0.75 mg/100 ml benzo(a)pyrene and caffeine (0.12 mg/100 ml) solution for 20 min at room temperature. Tumor cells were then injected s.c. in the foot pads of the donor rats. The length of time after injection for a primary tumor to increase in diameter by a factor of 1.6 was observed. In control rats receiving only the standard biopsy treatment, the length of time taken for tumors to exhibit this extent of growth was about 15 days (48 days maximum). In rats receiving the tumor cell-benzo(a)pyrene inocula, 18% of the tumors (7/39) had growth periods of more than 100 days. In 5 of these rats, the tumor regressed completely. Three of 7 tumors

this group grew more slowly or regressed after tumor-bearing rat had been inoculated with benzo(a)pyrene-treated allogenic tumor cells. Neither retardation of growth nor regression were observed in rats injected with tumor cells treated with caffeine alone, with nonmalignant mammalian cells or with bacterial cells which had been coated with benzo(a)pyrene. These findings appeared to suggest that benzo(a)pyrene did not act by increasing strength of the tumor-specific antigen, for inoculation of carcinogen-allogenic treated tumor cells and inoculation of carcinogen-treated autologous tumor cells almost the same efficacy in tumor growth retardation.

1 THE RELATION OF METABOLISM TO MACROMOLECULAR BINDING OF THE CARCINOGEN BENZO(a)PYRENE, BY MOUSE EMBRYO CELLS IN CULTURE. (E.) Macan, M. E. (Roy. Cancer Hosp., London, England) and P. Brookes. *Int J Cancer* 6(3):496-505, 1970.

Monolayer cultures of mouse embryo cells were treated with benzo(a)pyrene (BP) and metabolism of the labeled compound (^3H -BP) and its macromolecular binding were observed. The kinetics of BP metabolism were dose-dependent; at concentrations of BP below 2-3 $\mu\text{moles/ml}$ medium, the concentration of metabolized BP decreased exponentially with time. At 6 and 12 hr BP administered in doses of 0.5 $\mu\text{moles/ml}$ had decreased to 70 and 50% of the original concentration, resp. At higher doses of BP there was a period of rapid metabolism followed by a progressive decline. At 6 and 12 hr, BP administered in doses of 10 $\mu\text{moles/ml}$ decreased to 90 and 92% of original concentrations, resp. At low doses of BP the binding of the hydrocarbon to RNA, DNA, and protein was proportional to the overall metabolism, with the result that the binding index, the ratio of bound BP to the amount of BP metabolized, was constant. At higher dose levels of BP, overall metabolism increased with dose, while binding declined off; this resulted in a fall in the binding index value below the constant values found for low doses. The decline in macromolecular binding at high doses of BP appears to preclude a single enzyme mechanism for the metabolism of the hydrocarbon. The findings also appear to suggest that it is the rate of binding of the hydrocarbon rather than its absolute level that is the limiting factor in normal cellular function.

2 ANALYSIS OF ANTIGENIC HETEROGENEITY WITHIN INDIVIDUAL 3-METHYLCHOLANTHRENE-INDUCED SARCOMAS. (E.) Prehn, R. T. (Inst. Cancer Res., Philadelphia, Pa.). *J Nat Cancer* 45(5):1039-1045, 1970.

The differential antigenicity of sections of single mouse sarcomas was investigated. Tumors induced by implants of 3-methylcholanthrene were cloned by moving small sections of tissue from each pole of tumor and establishing clones from each section in syngeneic mice. Test mice were then immunized with clones from each tumor section pair, and 10-15 days later were challenged with tumor cells from the same pair. The growth of the paired subline chal-

lenge tumors was noted weekly. The subline which grew better in immunized animals was arbitrarily designated subline B. There were marked differences in some cases between tumor growth of the 2 sublines in nonimmunized mice. In 1 group of mice, 36% of nonimmunized controls developed tumors of 5 mm in diameter when injected with cells from subline A and 98% of the mice injected with subline B developed tumors of this size. Sublines of a primary tumor appeared to immunize against challenge with cells from that subline rather than against cells from its paired subline. In 1 case, mice immunized with tumor cells of subline A developed tumors in 9% of cases when challenged with tumor cells of subline A; the same mice developed tumors in 42% of cases when challenged with cells of subline B. In this pair of tumor cells, it appeared that the individuality of sublines' antigenicity resulted from a complete lack of demonstrable antigenicity in one of the sublines, rather than from differences in antigenic specificity. In contrast to sublines obtained from primary tumors, sublines taken from 4th and 5th generation tumors showed no differences which might suggest individual specificity between the members of any subline pair. In addition to individual antigenic specificity in the one case, there were cases of cross-reactivity, in which subline B immunized against subline A. Differences in growth potential, immunizing capacity, and responsiveness to immunity were observed between subline pairs in some cases; however, there was no correlation between immunizing capacity of subline and its responsiveness to immunity. Immunizing capacity and responsiveness to immunity appeared to be partially independent variables which varied according to factors other than cellular antigen content. Changes seen during tumor transplantation were thought to be the result of clonal variation subject to selection and operating at random.

0943 PRESENCE OF ANTITUMOROUS AUTOANTIBODIES IN THE BLOOD OF BALB/c MICE WITH METHYLCHOLANTHRENE-INDUCED SARCOMA. (E.) Umansky, Y. A. (Kiev Res. Inst. Exp. Clin. Oncol., USSR), M. I. Federovskaya, E. P. Vetrova and L. P. Kaminskaya. *Neoplasma* 17(5):491-497, 1970.

The blood of mice with sarcomas induced by methylcholanthrene (MC) was examined for the presence of antitumor antibodies. Male mice were injected s.c. with 1 mg of methylcholanthrene; antibody assays were conducted on the blood of these mice before injection with the carcinogen, and subsequently at 1, 2 and 3 months after treatments; test sera were prepared from the same mice. Autoantibodies were found in sera from 16 of 19 tested mice. Three of 16 mice tested proved to be sensitive to the action of antibodies in their own sera by absorption tests. The cytotoxicity of the antibodies in sera from these 3 mice after the induction of tumors decreased proportionally to the increase in the numbers of added tumor cells. With the addition of 20×10^6 tumor cells, the cytotoxic index in mice before treatment, at 2 months after treatment, and at 3.5 months after treatment were 0.45, 0.3 and 0.15, resp. This immunosensitivity appeared at 2-4

months after injection of carcinogen in the 3 mice. Cytotoxicity was determined in the sera of all 19 treated mice; however, no correlation was found between the cytotoxicity of sera and the immunosensitivity of the tumors. Antitumor antibodies did not appear to affect the growth of the methylcholanthrene-induced tumors.

- 0944 3-METHYLCHOLANTHRENE-INDUCED THYROIDITIS IN BUFFALO STRAIN RATS. (E.) Reuber, M. D. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Arch Environ Hlth* 21(6):734-739, 1970.

The capacity of 3-methylcholanthrene to induce thyroiditis was investigated in Buffalo strain rats. Rats of both sexes were given 0.033% of 3-methylcholanthrene in their food for periods of 4-52 wk. The incidence of rats with thyroiditis increased with continued ingestion of 3-methylcholanthrene. At 4 wk after the commencement of treatment, 8 females had developed thyroiditis, and 1 of them had a severe case. Male rats did not evince severe thyroiditis until 12 wk of treatment (2 cases); however 11 males had thyroiditis 4 wk after the beginning of treatment. By 24 wk, 11/14 females and 8/12 males had severe thyroiditis. Evidently, severe thyroiditis develops suddenly rather than progressing from mild to moderate and then to severe thyroiditis. Protein-bound iodine values in 3-methylcholanthrene-treated rats killed between 4-24 wk were only slightly higher than values for untreated controls.

- 0945 EFFECT OF 3-METHYLCHOLANTHRENE ON HYPERPLASTIC AND EARLY NEOPLASTIC HEPATIC LESIONS INDUCED IN RATS BY CARBON TETRACHLORIDE. (E.) Reuber, M. D. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Nat Cancer Inst* 45(6):1237-1242, 1970.

The incidence of liver lesions induced by carbon tetrachloride in Buffalo rats treated with 3-methylcholanthrene (MCA) was investigated. Rats of both sexes aged 5-76 wk were given either carbon tetrachloride (1.3mg/kg s.c.) or MCA (0.033% in feed) or both. The administration of the 2 agents did not markedly affect the survival of rats in the 3 test groups, with survival times ranging from 9-12 wk across test groups. In male rats given carbon tetrachloride only, hepatic hyperplastic nodules began to appear in 8, 24 and 52 wk-old animals; 1 hepatocellular carcinoma developed. Hyperplastic nodules were induced by carbon tetrachloride and MCA in male animals of all ages; carcinomas were seen in rats 12 wk and older. The incidence of nodules and carcinomas increased with age in male animals receiving both agents. More female rats aged 12-52 wk which were given carbon tetrachloride alone developed hyperplastic nodules than did male rats in the same age groups; females of this age group showed the highest incidence of nodules. Carbon tetrachloride and MCA increased the incidence of nodules and carcinomas in females 24, 52 and 76 wk-old more than in males. Rats given carbon tetrachloride alone had fewer lesions/

liver at autopsy than animals given both compounds; cirrhosis was also more severe in rats in the latter group.

- 0946 INDUCTION OF TUMORS IN GUINEA PIGS BY INTRAMEDIASTINAL INJECTION OF METHYLCHOLANTHRENE. (Pol.) Tlolkka-Pluszczyk, J. (Acad. Med. Wroclaw, Poland). *Pat Pol* 21(4):679-696, 1970.

In order to investigate the role of the carrier used for the administration of a carcinogen, methylcholanthrene (MC) was injected as a 3% suspension in gum arabic or bovine serum into the anterior mediastinum of randomly bred 4-10 month-old guinea pigs. Test animals were given single doses of 15 mg MC in 0.5 ml gum arabic (group I, 35 guinea pigs) or 30 mg MC in 1 ml gum arabic (group II, 37 guinea pigs). Groups III and IV were given single doses of 15 mg MC in 0.5 ml or 30 mg in 1 ml of bovine serum (54 and 60 animals, resp.). Group V was given 15 mg MC in 0.5 ml bovine serum twice at a 4 wk interval. Twenty percent of the guinea pigs of group I and 30% of group II developed tumors. None of the guinea pigs of group III, 12% of the guinea pigs of group IV and none of the animals of group V developed tumors. The average weight of the tumors which occurred at different sites was 59 g in the animals of group I, 64 g in the animals of group II and 13 g in the animals of group IV. All the tumors were constituted of single nodules of sarcomatous character, except one which was a chondroblastoma. The carrier used for the administration of MC appears to have a definite effect on the carcinogenic action of methylcholanthrene.

- 0947 INDUCTION OF CANCER BY 20-METHYLCHOLANTHRENE IN DIFFERENT REGIONS OF THE RAT STOMACH. (E.) Arkhipov, G. N. (Acad. Med. Sci., Moscow, USSR). *Cancer Res* 30(11):2739-2743, 1970.

A method of introducing carcinogens into the stomach of mice and rats was developed and employed in tumor-induction experiments in various parts of the rat stomach by 3-methylcholanthrene (3-MC). The carcinogen was placed in an ampul which was pierced with 2, 3 or many holes; the ampul was inserted in the stomach surgically and located in a stomach pocket created by closing off a small area of the stomach wall with a wire fastener. The carcinogen was intended to leach out of the ampul onto the stomach mucosa. It was found that best effects were obtained when 3-MC (5mg) was mixed in the ampul with Vaseline petrolatum jelly as a vehicle; optimum results were achieved with ampuls perforated with 36-40 apertures. Using Vaseline petrolatum jelly and a multi-perforate ampul, 6 adenocarcinomas were induced in the stomachs of 30 rats after 11 wk, while rats given ampuls with fewer apertures developed fewer tumors after longer latencies. In an experiment designed to determine the relative susceptibility of different parts of the rat stomach to tumorigenesis by the ampul method, ampuls containing 3-MC were placed in the forestomach, cardia, fundus and pylorus of rat stomachs (33 animals in each experimental group). After 16 months,

of 27 surviving rats had developed forestomach tumors, 9 of 30 rats had developed tumors in the duodenum area, 2 of 31 rats had developed tumors in the fundus, and 6 of 29 rats had developed tumors in the pylorus. Morphologically, tumors were cornifying squamous cell carcinomas and adenocarcinomas.

3 SPECTROPHOTOMETRIC DETERMINATION OF 20-METHYLCHOLANTHRENE IN DIFFERENT MEDIA. (E.) Vlasov, N. N. (N. N. Petrov Sci. Res. Inst. Biol., Moscow, USSR). *Vop Onkol* 16(9):90-91, 1970.

Spectrophotometric method for the quantitative determination of 3-methylcholanthrene (3-MC) in *n*-hexane soln at λ_{\max} = 295 m μ for the study of its retention and distribution characteristics in experimental carcinogenesis is described. An application of the method is illustrated in a group of rats subjected to surgical implantation of 3-MC (100 μ g) containing paraffin-filled pellets in the bladder wall. Approximately 20% of the 3-MC was removed from the pill 6 months and 40% 12 months after implantation. Urine 3-MC determinations on 12 rats revealed 18-20 ng of 3-MC excretion which corresponded to the decreases observed in the paraffin pills at 6 and 12 months intervals. The method allowed the degree of 3-MC retention within the paraffin pill and the potency of the carcinogenic effect of 3-MC upon the bladder wall to be evaluated. This method can be applied to any carcinogen having a characteristic absorption in the 280-300 m μ region.

4 A LEUKAEMOID RESPONSE IN 3-METHYLCHOLANTHRENE-TREATED RF STRAIN OF MICE. (E.) Kalka, T. (Christie Hosp., Manchester, England) and W. Craig. *Neoplasma* 17(5):499-504, 1970.

Effects of topical epidermal treatment with 3-methylcholanthrene (MC) on mice were investigated. Twenty-two mice (RF) of both sexes and various sub-strains were given a single brush stroke on 4 areas of dorsal skin of MC in a 0.5% solution in benzene. The treated area received an application once every 2 weeks for 20 wk. Fifty-nine of the 72 mice developed squamous cell carcinoma beginning at 84 days after the first treatment. Of these 59 mice, 55 developed a leukemoid reaction. Squamous cell carcinomas of the lungs metastasized only to lymph nodes and lungs. Thirteen mice developed lymphocytic leukemia or lymphoma, mainly of the thymic type; 5 cases of lymphoma were complicated by a severe leukemoid reaction. Major sites of leukemoid reaction were spleen (94% of cases), liver (83% of cases), and lymph nodes (93% of cases). Bone marrow cells from 19 mice diagnosed as having myeloid leukemia were injected i.v. into normal mice. Nine of the recipients developed typical lymphoma after 16-51 days; of the remaining 39 injected mice, 17 were symptom-free 1 yr later. Cell transplantation into syngeneic mice from mice with malignancy was regarded as a valuable practice for determining the essential nature of the malignancy in the donor animals.

0950 CELLULAR ANALYSIS OF RENAL NEOPLASIA: LIGHT MICROSCOPE STUDY OF THE DEVELOPMENT OF INTERSTITIAL LESIONS INDUCED IN THE RAT KIDNEY BY A SINGLE CARCINOGENIC DOSE OF DIMETHYLNITROSAMINE. (E.) Hard, G. C. (Med. Res. Council Lab., Carshalton, Surrey, England) and W. H. Butler. *Cancer Res* 30(11):2806-2815, 1970.

Histogenesis of renal mesenchymal tumors in rats conditioned by a protein-depleted diet and rats fed a casein-supplemented diet was explored through induction of lesions with dimethylnitrosamine utilizing an *in vivo* perfusion fixation technique. A single i.p. dose of 50 or 60 mg/kg dimethylnitrosamine was administered one week after commencement of the protein-free powder diet. At the same time 30 mg/kg dimethylnitrosamine was administered to rats fed the casein-supplemented powder. At selected times rats from each of the experimental groups and the control group were prepared for histological examination. All rats receiving 60 mg/kg dimethylnitrosamine examined at each stage beyond 3 days were found to have interstitial lesions. Ninety percent of protein-depleted rats treated with 50 mg/kg dimethylnitrosamine and 30% of protein-supplemented rats receiving 30 mg/kg possessed interstitial lesions beyond 3 days with no difference in character of lesions found in rats given injections of high or low doses of dimethylnitrosamine. In the control protein-depleted rats, only occasional very early foci of nephropathy at 25 wk were apparent. The first lesions were observed between 2 and 4 days after dimethylnitrosamine treatment with the formation of focal aggregations of cells, invariably near the glomeruli. After the acute response had passed at 7-14 days, hypercellular foci became progressively less and those which persisted showed increase in plasma cells. At 12 wk immunological cells disappeared and the remaining lesions assumed the character of very small tumor cell aggregations, which by 16 weeks had developed into unequivocal microscopic tumors. Mitoses were observed in lesions, most frequently at 7-14 days when the interstitial cell reaction was maximal and from 16 wk when tumor morphology was established. In accord with conclusions of several groups of workers, present results indicate that the various histological forms of dimethylnitrosamine-induced mesenchymal tumors derive from a single cell type near the glomerulus since development is preceded by the same progression of early interstitial change.

0951 THE FORMATION OF VARIANTS WITH A REVERSION OF PROPERTIES OF TRANSFORMED CELLS: V. REVERSION TO A LIMITED LIFE-SPAN. (E.) Rabinowitz, Z. (Weizmann Inst. Sci., Rehovoth, Israel) and L. Sachs. *Int J Cancer* 6(3):388-398, 1970.

The reversion of properties of transformed cells was studied in variants produced by dimethylnitrosamine (DMNA)-transformed hamster embryo cells. Variant cells were flat epithelioid cells compared to the parental transformed cells which were fibroblastic with a random growth pattern. Fixed normal cells provided 16-44% variants which were inhibited

by cells from the same clone or from another variant and by the parental transformed cells. The variants had lower saturation density ($3-4 \times 10^6$ cells) than the parental cells ($12-14 \times 10^6$ cells) as well as lower cloning efficiencies in fluid medium (3-11% compared to 71%) and in soft agar (0.1-5% compared to 31%); inoculation (s.c.) of 10^6 variant cells was required to parallel the *in vivo* tumorigenicity of 10^3 parental transformed cells. Subcultured transformed cells remained viable on fixed normal cells or feeder layers, but 81-85% of the variants from DMNA-transformed cells and 87-93% of the variants from benzo(a)pyrene- or X-irradiation-transformed cells terminated their life-span; only 5% of the variants from polyoma virus-transformed cells lost their viability. Escape from the limited life-span (which was determined intracellularly) by 15-19% of the variants from the DMNA-transformed cells was due to a re-reversion from the reverted to the transformed state.

- 0952 CELLULAR ANALYSIS OF RENAL NEOPLASIA: INDUCTION OF RENAL TUMORS IN DIETARY-CONDITIONED RATS BY DIMETHYLNITROSAMINE, WITH A REAPPRAISAL OF MORPHOLOGICAL CHARACTERISTICS. (E.) Hard, G. C. (Med. Res. Council Lab., Carshalton, Surrey, England) and W. H. Butler. *Cancer Res* 30(11):2796-2805, 1970.

The development of renal tumors in rats treated with dimethylnitrosamine (DMN) and maintained on protein-deficient and protein-supplemented diet was investigated. Male rats were given either a protein-free diet, a diet containing 30% protein (casein), a normal diet, a diet of sucrose granules for 1 wk or were starved for 64 hr. All groups were then given injections of 30-60 mg DMN; the rats on the protein-free diet were kept on that for 1 wk more and then returned to a normal diet; all other animals were put on normal diets after DMN administration. A quarter of the rats given conventional diet survived the administration of 60 mg DMN, while 44% of protein-depleted rats given 60 mg and 58% of those given 50 mg survived the initial toxic reaction to the carcinogen. All protein-depleted rats given 60 mg DMN developed renal epithelial tumors (4 adenocarcinomas and 13 mesenchymal tumors). Eighty-seven % of protein-depleted rats given 50 mg DMN developed tumors, and only 28% of rats fed with protein-supplemented food and given 30 mg DMN developed tumors. Rats on the conventional diet given 60 mg DMN developed tumors in 35% of cases, while the percentage of animals developing tumors among those given sucrose granules and 50 mg DMN was 89%. Starved rats given 50 mg DMN developed tumors in 86% of cases, while uninjected controls who had been given a protein-deficient diet developed no tumors. There were 96 mesenchymal tumors and 27 adenocarcinomas in 116 DMN-treated animals. The DMN-induced renal mesenchymal tumors apparently were not nephroblastomas, and all epithelial components other than independently developed adenomas or adenocarcinomas were consistent with pathologically-altered pre-existing renal parenchyma. Mesenchymal tumors appeared to differentiate into the various components of vascular tissue including spindle-shaped, fibro-

blast-like cells, smooth muscle cells, and vascular channels.

- 0953 RESPONSIVENESS OF NORMAL AND TRANSFORMED RAT EMBRYO CELL CULTURES TO POLY I-POLY C AND INTERFERON. (E.) Freeman, A. E. (Microbiol. Assoc., Bethesda, Md.), C. P. Uhlendorf, P. E. Younkers and S. Baron. *J Cell Physiol* 76(3):365-372, 1970.

In the present study a number of normal, virus-infected, and transformed (spontaneous or diethylnitrosamine-induced) pooled Fischer rat embryo cell lines were tested for responsiveness to the interferon inducer, polyinosinic-polycytidylic acid (poly I-poly C) and to exogenous interferon. Of the three cell pools assayed at two subculture levels, one culture lost its responsiveness to poly I-poly C and to interferon upon subculture; a second was more responsive; a third became more sensitive to interferon only. Degree of sensitivity of rat cells to poly I-poly C was independent of treatment and of morphological transformation and was unrelated to virus infection. The interpretation is that the degree of interferon responsiveness influences the rate of transformation but is not an absolute requirement of cellular transformation.

- 0954 INCREASED RENAL CARCINOGENESIS BY DIMETHYLNITROSAMINE IN PROTEIN DEFICIENT RATS. (E.) McLean, A. E. M. (U. Coll. Hosp. Med. Sch., London, England) and P. N. Magee. *Brit J Exp Path* 51(6):587-590, 1970.

The effect of a protein-deficient diet on the development of renal carcinomas in rats given dimethylnitrosamine was investigated. Male rats were fed a protein-free diet for 7 days before being given a single i.p. dose of 60 mg/kg dimethylnitrosamine. All 14 of the surviving rats developed renal tumors between 8-11 months after dimethylnitrosamine injection. Tumors were multifocal in many cases and originated from the epithelium or interstitial cells. Two pulmonary adenomas were also found. None of the untreated controls had developed tumors at 7 months. When animals injected with dimethylnitrosamine were given phenobarbital and/or DDT doses, it was found that phenobarbital did not protect against the carcinogenic action of dimethylnitrosamine; 3 of 3 rats fed a protein-free diet and given phenobarbital developed tumors and 1 of 2 rats fed a protein-free diet and given DDT developed tumors.

- 0955 ULTRASTRUCTURE OF LIVER CELL CARCINOMA IN *MACACA MULATA* MONKEY. (E.) Williams, A. C. (Dept. Path., U. Ibadan, Nigeria). *Exp Molec Path* 13(3):359-369, 1970.

Four hepatocarcinomas induced by N-nitrosodiethylamine in rhesus monkeys were examined under the electron microscope; 2 of the tumors were well-differentiated carcinomas, and 2 were poorly differentiated carcinomas. Monolayer and suspension cell cultures of tumor cells were also examined. Well-differen-

ated carcinomas had scanty rough endoplasmic reticulum and abundant free ribosomes. Rough cisterns occasionally enveloped mitochondria. The cristae sometimes traversed the width of the mitochondria, producing a dumb-bell effect. Microbodies were not frequent in well-differentiated carcinomas as in poorly-differentiated carcinomas. Large vacuoles were not uncommon, and lipid bodies were sometimes frequent. The hepatic cell membranes had microvilli. Most nuclei were rather large, with irregular outlines. Poorly-differentiated hepatocarcinomas had abundant smooth endoplasmic reticulum and smaller mitochondria with fewer cristae than the mitochondria of the well-differentiated tumors. Poorly-differentiated tumors had less well-developed and less orderly cytoplasmic organelles than well-differentiated tumors, including mitochondria and ergastoplasm.

- 56 ANTIGENICITY OF DIETHYLNITROSAMINE-INDUCED RAT HEPATOMAS. (E.) Garisoain, M. (Felix Huarte Ctr. Biol. Invest., U. Navarra, Complona, Spain) and J. M. Arcos. *Acta Oncol* 11:40-47, 1970.

The antigenicity of diethylnitrosamine-induced (approximately 4.2 mg/kg/day, p.o.) rat hepatomas was studied by immunoelectrophoresis and precipitin reactions. Direct immunoelectrophoretic analysis of the hepatoma against anti-normal liver immunoserum and against anti-hepatoma immunoserum yielded complex patterns similar to those obtained with normal livers. A specific hepatoma antigen (DEN-86) not found in normal liver homogenates was observed with relative electrophoretic mobility of 86%. DEN-86 is not glycidic or lipid in nature, showed no esterase activity, and had a high resistance to temperature and ultrasonic vibrations (20 min at 100°C and 60 min of ultrasonic vibration did not significantly alter the antigen). Preliminary localization tests indicated that the antigen sedimented in the nuclear fraction (700 x g), but after violent centrifugation of the hepatoma (Ultra-turrax at 15,000 rpm for 5 min) the antigen did not sediment after 1 hr at 150,000 x g.

- 57 SPECIFIC CHANGES IN CELLULAR RESPONSE TO HOMEOSTATIC CONTROL DURING DIETHYLNITROSAMINE-INDUCED LIVER CARCINOGENESIS. (E.) Rabes, R. (Pathologisches Institut der Universität, München, Germany) and P. Scholze. *Experientia* 26(12):1356-1359, 1970.

The growth behavior of preneoplastic liver cells was studied in rats following the administration of 100 mg of diethylnitrosamine (DEN) daily in drinking water; some rats were partially hepatectomized. Methylated thymidine (100 µC injected i.p.) was used to monitor DNA synthesis. By 10 days after the start of DEN treatment, the growth fraction of liver cells showed characteristic changes; glucose-6-phosphatase and adenosine triphosphatase activity were most pronounced around the portal field, falling off toward the lobular center. Cells in DNA synthesis were restricted to areas of highest enzyme activity, and there were no DNA synthesizing cells

in the area encircling the central vein of the liver. Both DNA synthesis and enzyme activity in these areas were restored when carcinogen-feeding was discontinued. After 40 days of DEN feeding, the areas of complete enzyme deficiency became sharply circumscribed. Simultaneously with the loss of enzyme activity, cells regained their ability to respond to homeostatic regulation. After partial hepatectomy, 90% of cells in the enzyme-deficient areas were labeled with tritiated thymidine. Liver cells, which were considered preneoplastic, showed little proliferation until 90 days after the start of DEN feeding in the absence of a growth stimulus; when a growth stimulus was provided by partial hepatectomy, however, they proliferated rapidly. Transformation of prospective tumor cells into autonomous hepatomas apparently proceeded in 3 stages: a stage of reduced enzyme activity coincident with loss of ability to proliferate; a stage of complete loss of enzyme activity in acinocentrally located groups of cells coincident with a return of the ability to proliferate, which was usually confined to cells provided with a proliferation-stimulus (partial hepatectomy); and a stage of autonomous proliferation of these enzyme-poor cells without additional growth stimulus.

- 0958 RESPONSE OF ADULT MASTOMYS (*PRAOMYS NATALENSIS*) TO SUBCUTANEOUS INJECTION OF N-NITROSODIMETHYLAMINE. (E.) Fujii, K. (Nat'l. Inst. Hyg. Sci., Tokyo, Japan) and H. Sato. *Gann* 61(5):425-434, 1970.

Tumorigenesis induced by the carcinogen N-nitrosodimethylamine in mastomys (*Praomys natalensis*) was investigated. Animals were given s.c. injections of the carcinogen twice a wk for 10, 19, 27, 36, and 44 wk in doses totaling 2.0, 3.8, 5.4, 7.1 and 8.8 mg. Males treated for more than 27 wk showed shorter mean survival times than males treated for less than 19 wk, an effect not noted for females. Mean survival for males treated for 19 wk was 56 wk, and 23 wk for males treated for 36 wk. Liver tumors developed in 4 untreated females and in 7 treated males; none of the treated females developed liver tumors. Tumors in controls were diagnosed as hepatocellular carcinoma or hyperplastic nodules, while tumors developing in treated animals included cholangiocystadenoma or cholangiocarcinoma; average latent periods for liver tumors in treated animals were 53-56 wk. Incidences of stomach tumors in treated males were from 33-41%. The incidence and latent period of liver tumors did not show dose correlations, and the incidence of stomach tumors in treated males was lower than in untreated males. Other tumors found in treated mastomys included pituitary adenoma, thymic lymphoma and adrenal adenoma.

- 0959 THE EFFECT OF PARTIAL HEPATECTOMY ON DIETHYLNITROSAMINE HEPATOCARCINOGENESIS IN RATS. (Ger.) Grünthal, D. (Gyn. Clin. Univ. Hamburg, Eppendorf, Germany) D. O. Hellenbroich, P. Sängner, and H. Maass. *Z Naturforsch* 25 b(11):1277-1281, 1970.

The effect of regeneration processes following partial hepatectomy on diethylnitrosamine (DENA) hepatocarcinogenesis was studied in 2 sets of experiments with female Wistar rats. In the first experiment, total survival time was determined in: A) 10 rats subjected to a 2/3 hepatectomy at the beginning of DENA treatment (2 mg daily in drinking water till termination); B) 10 rats subjected to a similar hepatectomy after 86 days of DENA intake; and C) 10 rats exposed to DENA treatment without hepatectomy. In the second experiment, 60 rats were subjected to 5 partial hepatectomies and intermittent DENA treatment as follows: D) 24 rats were subjected to partial hepatectomy and subsequently given DENA; E) 24 rats were given 9 mg/kg DENA in drinking water 1 wk after partial hepatectomy for 3 consecutive days; and F) 12 rats were given DENA under similar conditions as group E but without hepatectomy. Partial hepatectomies were performed subsequently at 14 day intervals with a 4 wk interval after the 3rd operation. DENA was given after each operation (3.9 mg/kg daily with 14 day intervals for 28 wk) until a total of 351 mg/kg per rat was administered. The average survival time in the first experiment decreased from 225 days (control group C to 158 days in group A), and all the animals developed liver carcinomas. In the second experiment the mitotic rate in group D was 70% higher (not significant) than in group E. Histological investigation of resected liver segments from live and dead rats showed (according to Grundmann and Sieburg) conditions referred to as stage I through the 6th wk, stage IIa between the 10th-18th wk and stage IIa-IIb between the 20th-28th wk of the experiment. Of the 20 surviving rats at the 40th wk of the experiment, 3 rats from group D had dedifferentiated carcinoma, 1 rat from group E had a partially dedifferentiated carcinoma and in group F 9 rats developed microcarcinomas while only 2 rats developed carcinoma. Enzyme activities (phosphorylating enzymes and the LDH/GPDH ratio) in premalignant tissues showed no differences from normal liver tissue. However, the proliferative processes during liver regeneration seemed to promote DENA hepatocarcinogenesis.

0960 HISTOCHEMICAL INVESTIGATIONS IN RAT LIVER DURING DIETHYLNITROSAMINE HEPATOCARCINOGENESIS. (Sp.) Hernandez, F. (Fac. Med. U. Navarre, Spain) and J. Martinez de Morentin. *Rev Med Univ Navarra* 13(2):175-183, 1970.

Histochemical investigations of malate, lactate, glutamate, succinate, β -hydroxybutyrate and α -glycerophosphate dehydrogenases, NADH and NADPH dependent diaphorases, acid and alkaline phosphatases, nonspecific esterases and ubiquinone were made in liver tissues during diethylnitrosamine (DENA) carcinogenesis in Wistar rats given 5 mg DENA/kg p.o. daily for 22 wk. During this period 1 control and 3 treated rats were sacrificed weekly. The first nodules of hepatoma appeared on the 18th wk of the experiment. Two distinct stages in DENA carcinogenesis were noticed: the first stage lasted 10-14 wk and was characterized by a decrease in Krebs cycle specific enzymes such as succinate, glutamate

and malate dehydrogenases, while lactate and α -glycerophosphate dehydrogenases were unchanged. The second stage of the process (between wk 10-14 through wk 22) was characterized by an increase in β -hydroxybutyrate dehydrogenase (related to fatty acid metabolism) and α -glycerophosphate dehydrogenase (glycolysis) and in alkaline phosphatase (membrane transport mechanisms) occurring in isolated preneoplastic cell groups. No differences in diaphorase and ubiquinone levels were noticed. A decrease in acid phosphatase was noticed beginning from the 8th wk of the experiment within the lysosomal areas. The hepatoma tissues exhibited generally low levels of these enzyme activities. The role of acid phosphatase in DENA carcinogenesis is discussed.

0961 CELLULAR INJURY AND CARCINOGENESIS: INHIBITION OF METABOLISM OF DIMETHYLNITROSAMINE BY AMINOACETONITRILE. (E.) Fiume, L. (Max Planck Inst. Med. Res., Heidelberg, Germany), G. Campadelli-Fiume, P. N. Magee and J. Holsman. *Biochem J* 120(3):601-605, 1970.

The inhibition of dimethylnitrosamine by aminoacetonitrile was investigated in rat liver *in vivo* and in rat liver slices *in vitro*. The rate of disappearance of dimethylnitrosamine from the circulating blood of rats to which it had been administered in doses of 30 mg/kg body wt was decreased by treatment of the animals with aminoacetonitrile (200 mg/kg body wt). Rats receiving dimethylnitrosamine alone had blood levels of 4 μ g/ml at 6 hr after administration, while rats given aminoacetonitrile and dimethylnitrosamine did not exhibit this level of dimethylnitrosamine in the blood until 47 hr after treatment. Aminoacetonitrile also inhibited metabolism of dimethylnitrosamine *in vitro*. The methylation of rat liver and kidney nucleic acids *in vivo* by 14 C-dimethylnitrosamine showed that aminoacetonitrile inhibited the incorporation of the labeled compound into proteins of both organs 4-12 hr after injection. Four hr after treatment, the labeled dimethylnitrosamine content of rat livers without aminoacetonitrile was 120 cpm/mg, while that for rats given aminoacetonitrile was 48 cpm/mg. The observed inhibition of dimethylnitrosamine metabolism by aminoacetonitrile explains the ability of this agent to prevent the appearance of dimethylnitrosamine-induced liver tumors.

0962 CARCINOGENICITY OF A SINGLE ADMINISTRATION OF N-NITROSOMETHYLUREA: A COMPARISON BETWEEN NEW-BORN AND 5-WEEK-OLD MICE AND RATS. (E.) Terracini, B. (Inst. Anat. Path., U. Turin, Italy) and M. C. Testa. *Brit J Cancer* 24(3):588-598, 1970.

The carcinogenic effects of N-nitrosomethylurea (NMU) on newborn and weaned mice and rats was investigated. Hybrid mice (C57BL x C3Hf) F_1 and Wistar rats were given a single i.p. injection of NMU (50 μ g/g body wt) when newborn or at 5 wk of age. Eleven of 95 mice treated at birth died before weaning compared with 3 of 34 untreated controls; early deaths did not occur among mice treated at 5 wk. Body growth in mice treated at

Birth was consistently impaired; the wt of treated mice at 50 wk-of-age was 17 g, while the wt of controls at this time was 30 g. Seven percent of mice treated at birth and 21% of mice treated at 5 wk were tumor free, compared to 97% of controls. Of the male mice treated at birth, 58% had lymphosarcomas, 80% had lung adenomas, 84% had hepatomas, and 20% had renal adenomas. Of the male mice treated at 5 wk of age, 31% had lymphosarcomas, 40% had lung adenomas, none had hepatomas, 9% had renal adenomas, and 36% had tumors of the forestomach. The pattern of tumor occurrence was similar in female mice except for a higher incidence of forestomach tumors and a lower incidence of hepatomas (5% in female mice treated at birth). Growth depression comparable to that seen in mice occurred in NMU-treated rats. In male rats treated with NMU at birth, incidences of 10% lymphosarcomas, 77% renal anaplastic tumors, 21% renal adenomas, 28% forestomach tumors, and 30% intestinal adenocarcinomas were seen; similar tumor incidences were found in female rats except for 50% forestomach tumors, 100% intestinal adenocarcinomas, and 28% mammary tumors. Female and male rats injected at 5 wk-of-age developed 9% and 75% lymphosarcomas, 8% and 54% renal anaplastic tumors, 0% and 25% renal adenomas, no forestomach tumors, 0% and 50% intestinal adenocarcinomas, and 60% and 0% mammary tumors, resp. Multiple tumors in the same animal were frequently seen. Since NMU breakdown is rapid and may not require an enzyme, it seems that factors other than the degree of maturation of enzyme production are responsible for the differential susceptibility among newborns and young adult mice to carcinogenesis by this compound.

963 EXPERIMENTAL BRAIN TUMOURS INDUCED IN RATS BY NITROSOUREA DERIVATIVES: I. MORPHOLOGICAL ASPECTS OF METHYLNITROSOUREA TUMOURS. (E.) Schiffer, D. (Clin. Nerv. Mental Dis., U. Turin, Italy), P. Fabiani, E. Grossi-Paoletti and P. Paoletti. *J Neurol Sci* 11(6):559-572, 1970.

Long Evans male rats received 25 mg/kg of methylnitrosourea by injection in the tail vein once a month for 6 months, starting in the second month of life. Twenty-nine (80%) of 36 treated animals developed neoplasms of the brain; 12 rats had a solitary tumor, 6 of which were glial, and 17 animals had multiple tumors. Forty-eight of the tumors were intracranial tumors and included 17 oligodendrogliomas, 5 isomorphous gliomas, 10 polymorphous gliomas, 10 glial foci, 2 neurinomas, 2 sarcomas, an epithelial cyst, a plexus papilloma and a spinocellular carcinoma. Eight spinal tumors were also found; these included 4 isomorphous gliomas, 1 polymorphous glioma, a glial focus and 2 neurinomas.

964 EXPERIMENTAL BRAIN TUMOURS INDUCED IN RATS BY NITROSOUREA DERIVATIVES: II. MORPHOLOGICAL ASPECTS OF NITROSOETHYLUREA TUMOURS OBTAINED BY TRANSPLACENTAL INDUCTION. (E.) Grossi-Paoletti, P. (Inst. Pharmacol., U. Milan, Italy), P. Paoletti, D. Schiffer and A. Fabiani. *J Neurol Sci* 11(6):573-581, 1970.

Long Evans female rats were given 10 mg/kg of ethylnitrosourea i.v. on the 17th day of pregnancy; the 46 offspring, which appeared normal at birth, were sacrificed 150-400 days later, and the pathology of the central nervous system was studied. Fifty-eight neoplastic proliferations of cells were observed in 41 of 46 treated rats (89%). The occurrence of multiple tumors increased as the time interval before sacrifice was increased. Forty intracranial tumors (21 neurinomas, 11 oligodendrogliomas, 6 oligodendroglial foci, and ependymoma and a glioblastoma) and 18 spinal tumors (14 neurinomas, 3 oligodendrogliomas and an ependymoma) were found. Neurinomas of the Gasserian ganglion and spinal neurinomas were the first to occur; multiply associated neurinomas and neurinomas occurring with oligodendroglial hyperplasia followed by oligodendrogliomas were next to be seen. Three of the 21 Gasserian ganglion neurinomas and 1 of the 13 spinal neurinomas showed characteristics of high histological malignancy.

0965 NERVE TUMORS EXPERIMENTALLY INDUCED BY APPLICATIONS OF N-METHYL-N-NITROSOUREA IN RATS: III. ELECTRON MICROSCOPIC STUDIES. (Ger.) Jänisch, W. (Med. Acad. Erfurt, Germany), A. Lageman, W. Dietz and D. Schreiber. *Exp Path* 4(5-6):317-328, 1970.

An electron microscopic investigation of the histogenesis of 10 experimentally induced tumors of the peripheral nerves and spinal nerve roots in rats is presented. Of these, 9 resulted from the i.v. injection of N-methyl-N-nitrosourea (10-25 mg/kg 2-4 times weekly), and in another rat a tumor of the cauda equina, of the lumbosacral plexus, and of both adrenals was produced with ethylnitrosourea. Three types of growth were distinguished in these tumors. The first group included those parts of the tumor with loose cell formation and wide intracellular spaces. Most of these cells were surrounded by basement membranes from which long thin processes protruded. These lamella-shaped processes were partially isolated and found in thick layers in the intercellular space. The nuclei of these cells were oblong and showed deep grooves. These cells were associated with tumors derived from Schwann's cells, in which a definite sign of abortive medullary formation was demonstrable in the tumor cells. The second group of findings comprised those tumors diagnosed by light microscopy as anaplastic tumors, and differed from the tumors in the first group in 2 ways: they were characterized by very few cells with a basement membrane, and the cell processes were short. No specific ultrastructural features could be found in these, and it is inconclusive whether these tumors were derived from the Schwann's cells as well. The third group was distinguished by the thick processes associated with the cells; they were thickly packed and ran parallel to each other and were often surrounded by a common basement membrane. The medullary sheaths were absent. These cells may be derived from a perineural origin.

0966 LACTIC DEHYDROGENASE ACTIVITY AND ISOENZYME PATTERNS IN EXPERIMENTAL TUMORS OF THE PERI-

PERIPHERAL NERVOUS SYSTEM OF THE RAT. (Ger.) Stavrou, D. (Med. Fac. Munich, Germany), M. Knedel and H. Kirzeder. *Ges Exp Med* 153(3):223-233, 1970.

The distribution of lactate dehydrogenase (LDH) and its isozymes and their electrophoretic separation from 22 experimentally induced neurinomas in rats is described. One group of 100 Sprague-Dawley rats was injected s.c. with 50 mg/kg phenyldimethyltriazine weekly, and a second group of 100 rats was supplied with drinking water providing 6 mg/kg N-methyl-N-nitrosourea (MNH) twice weekly, following a 12 hr period of water deprivation. The tumors investigated included nerve root neurinomas of the spine and cerebral nerves, as well as those of the cauda equina. The intensity of LDH activity varies from tumor to tumor and even within different areas of the same tumor, but this activity does not differ greatly in tumors which are similar in construction. High enzyme activity was found in reticular tumor sections, and LDH-positive cytoplasm was seen lying close to the nuclei. High enzyme activity was also seen in slightly vascularized tumor areas in contrast to a low activity in the highly vascularized areas. Agar gel electrophoretic separation of the LDH isozyme in the normal nerves of the rat showed 5 isozymes, with the cathodic isozyme LDH₅ having the highest activity. However, all 5 isozymes were not detectable in most of the tumors; the anodic LDH₁ band was usually negligible and the cathodic LDH₅ band showed highest activity.

0967 ELIMINATION, TISSUE ACCUMULATION, AND METABOLIC FATE OF 4-NITROQUINOLINE-1-OXIDE ADMINISTERED ORALLY IN RATS. (E.) Kato, R. (Natl. Inst. Hyg. Sci., Tokyo, Japan), A. Takahashi, W. Ngamwatana and Y. Omori. *Gann* 61(5):415-424, 1970.

The elimination, tissue accumulation, and metabolic fate of ³H-labeled 4-nitroquinoline-1-oxide was investigated in rats. Male rats were given ³H-4-nitroquinoline-1-oxide orally (15 mg/kg) and killed from 1-96 hr later, at which times the accumulation of the radioactive label in various organs and its elimination were observed. Radioactive substances were excreted through both fecal and urinary routes; in 48 hr, 57% of radioactive label was eliminated through the urine and 30% through feces. After 48 hr, excretion of the label from fecal and urinary routes was approximately equal. Total recovery from urine and feces of radioactive substances was about 90% of the oral dose. At 24-96 hr after administration, the stomach tissues contained 3-5 times more radioactivity than did other organs (136 cpm x 10³/g wet wt). Radioactivity was concentrated in the forestomach which contained about 82% of the total radioactivity in stomach tissue; specific activity was higher in the mucosa of the forestomach than in forestomach muscle tissue. Thin layer chromatography of extracts of each tissue was performed with acidic ethanol with the result that the radioactivity in the 4-nitroquinoline-1-oxide fraction was low in stomach tissues after 12 hr (4.8%). Radioactivity in the 4-aminoquinoline-1-oxide fraction was high in stomach tissues after 12

hr (48.8%), but radioactivity interacting with proteins and nucleic acids was not so high in liver and intestine as in stomach tissues.

0968 DNA REPAIR AND CHROMATID ANOMALIES IN MAMMALIAN CELLS EXPOSED TO 4-NITROQUINOLINE-1-OXIDE. (E.) Stich, H. F. (Cancer Res. Ctr., U. British Columbia, Vancouver, Canada) and R. H. C. San. *Mutat Res* 10(4):389-404, 1970.

DNA-repair synthesis (unscheduled DNA synthesis) was followed in normal, diploid, aneuploid, and neoplastic human and hamster cells after exposure to 4-nitroquinoline-1-oxide (4NQO). DNA-repair synthesis was separated from DNA-replication synthesis associated with chromosome replication at S-phase by maintaining the cultures in an arginine-deficient medium before 4NQO exposure. All of the cell types tested showed a high capacity for DNA-repair synthesis (94-100% of the nuclei incorporated ³H-thymidine), but the amount of incorporation into nuclear DNA of cells exposed to 4NQO depended on the dose of 4NQO (5 x 10⁻⁸ to 1 x 10⁻⁵M) and on the amount of DNA in the cell. A time course study of 4NQO-induced (5 x 10⁻⁶M for 1.5 hr) repair synthesis indicated that the synthesis was at a maximum (120-130 grains/nucleus) 2-4 hr after treatment and that it fell off rapidly thereafter to a near steady state rate (10-20 grains/nucleus). Cells were capable of starting with DNA replication at S-phase without having completed the DNA-repair synthesis, but passage of the cells from G₂ to metaphase was severely inhibited (80%) by 4NQO at 10⁻⁶M concentrations. Chromosomal responses to 4NQO included loosening of the coiled structures, single isochromatid and multiple breaks, and single and multiple chromatid exchanges.

0969 TUMORIGENIC EFFECT OF THIOACETAMIDE IN SWISS STRAIN MICE. (E.) Gothoskar, S. V. (Cancer Res. Inst., Bombay, India), G. V. Talwalkar and S. V. Bhide. *Brit J Cancer* 24(3):498-503, 1970.

The effect of treatment with thioacetamide on the livers of Swiss mice was investigated. Mice were fed a diet containing 0.03% thioacetamide, and livers were examined 6, 9, 13 or 17 months after commencement of treatment. Gross changes in the appearance of the liver, including granularity, increased liver wt, and darkened color were discernible in mice autopsied 13 months after the beginning of thioacetamide treatment. Nodular areas were seen on livers of mice killed after 17 months of treatment; no secondary lesions in other organs could be found in this group, however. In mice killed 6 months after beginning thioacetamide treatment, microscopic examination showed mild generalized hypertrophy of the hepatic cells; hypertrophy was more marked in the 9 month group in which bile-duct proliferation was observed. Mice killed after 13 months of treatment showed cirrhosis and cholangiofibrosis in 1 case. In this group, all treated males and 6/7 of the treated females developed hepatomas. Transplantation of these tumors to mice of the same strain produced palpable tumors

n 4-6 months. Both RNA and DNA levels in thioacetamide-treated liver tissue were comparable with levels in corresponding control groups. However, RNA and RNA levels in tumor tissue in males were significantly higher than those in the corresponding control livers; in mice killed 17 months after commencement of thioacetamide treatment, RNA levels in tumors were 0.25 μg of nucleic acid/ μg of protein, compared to 0.15/ μg in the controls. In the same experimental group, DNA levels were 0.20 μg nucleic acid/ μg protein while control values for DNA were 0.15 μg / μg protein.

970 STUDIES ON PROGRESSIVE METABOLIC ALTERATIONS IN THIOACETAMIDE INDUCED HEPATOCARCINOGENESIS. (E.) Bhide, S. V. (Cancer Res. Inst., Tata Mem. Ctr., Parel, Bombay, India). *Brit J Cancer* 24(3):504-509, 1970.

Progressive metabolic alterations in liver tissue of mice treated with thioacetamide were investigated; metabolic parameters studied included glycogen and lactic acid levels, glucose-6-phosphatase, fructose-1-6-diphosphatase, aldolase, aspartic and ornithine transcarbamylase, arginase, and xanthine oxidase activities. Mice were fed 0.03% thioacetamide in a normal diet. Glycogen content in treated mice decreased significantly from the age of 4 months; at this point glycogen content in control mice and thioacetamide-treated mice were 60.53 and 41.81 μg glucose/mg tissue, resp.; lactic acid levels in treated mice exceeded those in controls, with the change becoming evident at 9 months when lactic acid levels in control and treated mice were 1.2 and 4.8 μg lactic acid/mg tissue, resp. Glucose-6-phosphatase and fructose-1-6-diphosphatase activities were decreased in treated mice from the age of 4 months; the extent of decrease in enzyme activities in host liver and tumor were comparable. Thioacetamide treatment caused an increase in aldolase activity from the age of 9 months when aldolase activity values in control and treated mice were 0.9 and 1.3 μg triose-phosphate liberated/hr/mg tissue, resp. Aspartic transcarbamylase activity in treated mice increased from the age of 9 months, while ornithine transcarbamylase activity in treated mice decreased from the age of 13 months. Xanthine oxidase and arginase activity decreased in treated mice from the age of 9 months. Maximum changes in enzyme activities were observed in hepatomas at the age of 17 months.

0971 LIVER REGENERATION AND INDUCTION OF HEPATOMAS IN B6AF₁ MICE BY URETHAN. (E.) I. N. Chernozemski (Roy. Cancer Hosp., London, England) and G. P. Warwick. *Cancer Res* 30(11):2685-2690, 1970.

The effect of urethan injections on hepatoma formation in hepatectomized mice was investigated. Male and female mice were hepatectomized by a procedure which removed 63-69% of the liver. Hepatectomy was followed by urethan injections (1 mg/kg body wt) at 4-5 hr after surgery (i.e., at the early pre-replicative period for regenerating liver cells), at

17-18 hr after surgery (i.e., during the late pre-replicative period), at 31-33 hr after surgery (i.e., shortly before the onset of extensive regenerative DNA duplication), or at 46 hr after surgery (i.e., before the peak of mitosis in regenerating cells). One untreated control (no surgery, no urethan) developed a hepatoma (3.3% incidence), and 6 mice which had hepatectomies but no chemotreatment developed hepatomas (19% incidence). Among mice given urethan but not hepatectomized, 2 hepatomas developed (6% incidence), while among mice given urethan 4-5 hr after hepatectomy, 2 tumors developed (10% incidence). Of mice given urethan 17-18 hr after hepatectomy, 17 developed hepatomas (68% incidence); of those treated 31-33 hr after surgery, 11 developed tumors (52% incidence). Of mice given urethan 46 hr after hepatectomy, 20 developed hepatomas (77% incidence). The largest average number of tumors developed/mouse was 1.9 in mice of the group given urethan 17-18 hr after hepatectomy. Most of the mice developing tumors were males.

0972 ENHANCED METHODS OF DETECTION OF BLASTOGENIC PROPERTIES OF CHEMICAL COMPOUNDS: EXPERIMENTS WITH URETHAN. (Rus.) Zadorozhnaya, N. A. (All-Union Res. Inst. Hyg. Toxic. Pesticides, Polymers, Plastics, Kiev, USSR) and O. P. Chepinoga. *Vop Onkol* 16(9):71-73, 1970.

Experimental models were tested with urethan in order to establish faster methods for studies of chemical carcinogenesis; the effect of urethan in randombred white mice in the prenatal period was compared to effects produced at 2-3 months-of-age. The experimental mice were given urethan (1 mg/g body wt, i.p.) on the 17th and 19th day of pregnancy. The newborn mice were observed for 3 months at which time half of each progeny were sacrificed, and half were subjected to additional urethan treatment for 3 months (1 mg/g body wt on alternative days). These mice were then sacrificed at 6 months of age and examined for cancer incidence. An additional 2 groups of 3 month-old normal mice were given urethan 2 and 5 times (2 and 5 mg/g wt, resp.) on alternative days. Lung adenomas were found in 50% of the 3 month-old progeny of transplacentally treated animals and in 4% of the control mice. Additional urethan administration to the 3 month-old animals of this group produced adenomas in 88% of the mice at 6 months of age. The incidence of adenomas in the twice treated normal animals was 63% in 3 months. Higher doses (5 administrations) of urethan under similar conditions produced 90% tumor incidence in 3.5 months and seemed to constitute the most appropriate experimental model.

0973 EFFECTS OF CIGARETTE SMOKING ON DOGS: I. DESIGN OF EXPERIMENT, MORTALITY, AND FINDINGS IN LUNG PARENCHYMA. (E.) Hammond, E. C. (American Cancer Soc., New York, N.Y.), O. Auerbach, D. Kirman and L. Garfinkel. *Arch Environ Hlth* 21(6):740-753, 1970.

The effects of smoking filtered and unfiltered cigarettes on mortality, cause of death, and neoplastic development were investigated in beagle dogs.

Eighty-nine dogs were trained to smoke cigarettes through a tracheostoma, and were then given cigarettes over a test period of 875 days as follows: 6,143 filtered cigarettes, 3,103 unfiltered cigarettes, 6,129 unfiltered cigarettes, and no cigarettes (nonsmoking controls). Tar contents of filtered and unfiltered cigarettes were 17.8 and 34.8 mg tar, resp., and the nicotine contents of filtered and unfiltered cigarettes were 1.17 and 1.85 mg nicotine, resp. None of the nonsmoking dogs died before day 875; 2 of 12 filtered cigarette smokers died, 2 of 12 dogs smoking 3,103 unfiltered cigarettes died, and 24 of 62 dogs smoking 6,129 unfiltered cigarettes died. Common causes of death among smoking dogs included pulmonary infarction, and cor pulmonale. Noninvasive bronchiolo-alveolar tumors were found in the lungs of 12 dogs smoking 518-5,970 cigarettes. Invasive tumors were found in lungs of 4 dogs smoking from 3,928-5,030 cigarettes. Fibrosis and emphysema were found in the lungs of all smoking dogs. It was concluded that smoking cigarettes with an efficient filter will produce less damage to lung parenchyma than smoking unfiltered cigarettes.

- 0974 EFFECT OF CIGARETTE SMOKING ON DOGS: II. PULMONARY NEOPLASMS. (E.) Auerbach, O. (VA Hosp., East Orange, N.J.), E. C. Hammond, D. Kirman and L. Garfinkel. *Arch Environ Hlth* 21(6): 754-768, 1970.

The effect of smoking filtered and unfiltered cigarettes on mortality and pulmonary tumor development was investigated in beagle dogs. Eighty-six dogs trained to smoke through a tracheostoma were divided into 5 experimental groups: nonsmoking controls, smokers of 6,161-6,269 filtered cigarettes, smokers of 1,055-3,195 unfiltered cigarettes, smokers of 518-6,318 unfiltered cigarettes, and smokers of 3,769-5,400 unfiltered cigarettes. By the 875th day after the commencement of smoking, 2 filtered cigarette smokers, and 26 nonfiltered cigarette smokers had died, while none of the nonsmoking controls had died. While noninvasive bronchiolo-alveolar tumors were found in dogs from all 5 groups, invasive tumors were found only among dogs which smoked large numbers (e.g., more than 3500) of unfiltered cigarettes. Early bronchial squamous cell carcinoma was found in 2 dogs, both of which had smoked more than 6000 unfiltered cigarettes. Dogs with tumors in both bronchiolo-alveolar lobes were found in the group smoking unfiltered cigarettes heavily (20% of dogs in this group). Most bronchial tumors were multicentric, and none of the tumors was metastatic. It was concluded that cigarette smoking increases the risk of developing bronchiolo-alveolar tumors in dogs, and that the risk of tumor development is greater in dogs smoking unfiltered cigarettes than in dogs smoking filtered cigarettes.

- 0975 THE RESPIRATORY EFFECTS OF REGULAR CIGARETTE SMOKING IN WOMEN. (E.) Woolf, C. R. (Dept. Med., U. Toronto, Ontario, Canada) and J. T. Suere. *Amer Rev Resp Dis* 103(1):26-37, 1971.

The effect of cigarette smoking on pulmonary function and sputum production in women was investigated. Subjects were 298 normal Canadian women aged 25-54 yr and included 97 nonsmokers, 30 ex-smokers, 24 light (44 cigarettes/wk) smokers, 63 moderate (117 cigarettes/wk) smokers, and 84 heavy (187 cigarettes/wk) smokers. Prevalence of cough, sputum production, wheezing, and dyspnea increased with increased cigarette smoking. Only heavy smokers consistently reported having more than 4 colds/yr. Chest abnormalities were more frequent in smokers than in nonsmokers; abnormalities included decreased darkening of the lung field on fluoroscopy. Sputum specimens, which were more available from smokers than nonsmokers, showed no malignant cells; macrophages were found in equal amounts in sputum from both smokers and nonsmokers. Carbon particles were more frequent in the macrophages from smokers' lungs than in macrophages from the lungs of nonsmokers. Moderate epithelial squamous cell metaplasia and dyskaryosis were found more frequently in the heavy smokers (dyskaryosis occurring in 27% of nonsmokers, 15% of moderate smokers, and 39% of heavy smokers). Columnar cells were distributed similarly in smokers and nonsmokers, while lymphocytes were more frequent in the sputum of smokers than in the sputum of nonsmokers. Smokers had lower values than nonsmokers for forced vital capacity tests, forced expiratory volume in 1 sec tests, arterialized capillary blood oxygen at rest tests, pulmonary diffusing capacity tests, and tests of fractional uptake of carbon monoxide during exercise.

- 0976 SMOKING AND CANCER OF THE LOWER URINARY TRACT. (E.) Cole, P. (Harvard Sch. Publ. Hlth., Boston, Mass.), R. R. Monson, H. Haning and G. H. Friedell. *New Eng J Med* 284(3):129-134, 1971.

The association of cigarette smoking and transitional or squamous-cell carcinoma of the lower urinary tract was investigated in a survey of 470 cancer patients. More than 90% of the patients had bladder tumors. The age-specific incidence data for bladder cancer for males and females indicated that the risk of bladder cancer for men increases at a constant rate throughout life, while the risk for women began to increase after age 60. Male cigarette smokers had a relative risk of bladder cancer of 1.89 compared with nonsmokers and female smokers had a relative risk of 2.00. About 39% of male cases of bladder cancer were related to smoking, and about 29% of female cases were smoking-related. The highest number of bladder cancer cases among smokers occurred in male patients who smoked from $\frac{1}{2}$ -1 $\frac{1}{2}$ packs of cigarettes/day (140 observed cases). In both sexes, the risk of contracting bladder cancer was increased among smokers who inhale deeply. Attributable risks of bladder cancer for smokers increased with age; risks for patients aged 20-59 yr, 60-74 yr, and 75-89 yr being, resp., 10, 60 and 87 cases/100,000 population. None of the excess risk of bladder cancer associated with cigarette smoking was explained by any indirect association with occupational exposure. It appeared likely that incidence rates for bladder cancer among women will increase in the next 10 yr. Pipe and cigar smoking was not associated with a significant risk of bladder cancer.

0977 THE EPIDERMIS AND THE RESPIRATORY TRACT AS BIOASSAY SYSTEMS IN TOBACCO CARCINOGENESIS. (E.) Wynder, E. L. (Amer. Hlth. Found., New York, N.Y.) and D. Hoffmann. *Brit J Cancer* 24(3):574-587, 1970.

The carcinogenic effects of cigarette smoking have been investigated using the mouse epidermis as a bioassay system. The advantages of mouse skin were that it is responsive to tumorigenic substances in small doses, it responds only to carcinogens and not to non-specific physical agents, and it involves squamous epithelium, which must be formed before malignant transformation can take place in the respiratory epithelium. The smoke of 2 cigarettes, containing about 52 mg of moist particulate matter, was applied 3 times/wk to squamous epithelium of mouse skin. This technique has permitted the identification of tumor initiators in the "tar" fraction of tobacco smoke which included benzo(a)pyrene. Tumor "accelerators" have also been detected; these are components which exhibit neither carcinogenic activity nor tumor initiating activity, but which accelerate the activity of complete carcinogens when applied concurrently with them. Such tumor accelerators include trans-4,4'-dichlorostilbene, 5-methylindole, and 9-methylcarbazole. Tumor promoting agents identified by use of the mouse epidermal bioassay system have been found to reside in the weakly acidic (phenolic) and the acidic fractions of the smoke; the specific identity of these agents, however, remains to be determined. Apparently, the tumorigenicity of tobacco smoke "tar" declines significantly when pyrosynthesis of alkylated and non-alkylated polynuclear hydrocarbons is inhibited.

0978 THE EFFECTS OF BETEL-NUT CHEWING ON THE BUCCAL MUCOSA OF 296 INDIANS AND MALAYS IN WEST MALAYSIA: A CLINICAL STUDY. (E.) Chin, C. T. (Dist. Hosp. Kluang, Johore, West Malaysia) and K. W. Lee. *Brit J Cancer* 24(3):427-432, 1970.

The association of betel-nut chewing and changes in the buccal mucosa was investigated in a Malay and Indian population in West Malaysia, where the habit is widespread. The 212 Indians in the study ranged in age from 12-74 yr, and the 84 Malays ranged in age from 25-90 yr; 167 of the Indians incorporated tobacco in their betel-nut quids, while 45 of the Malays substituted gambir for tobacco in their betel-nut quids. Sixty-two percent of tobacco-chewing Indians showed changes in the buccal mucosa; of these changes 40% were designated "leukoplakia" and 23% were designated "preleukoplakia." Only 26% of non-tobacco-chewing Indians showed changes in the buccal mucosa; 9% of these changes were considered to be leukoplakia. Changes in the buccal mucosa were observed in 22% of gambir-chewing Malays, and 11% of these were regarded as leukoplakia and a similar proportion were regarded as preleukoplakia. Among non-gambir-chewing Malays, 25% showed changes, 12% with leukoplakia-like conditions, and 12% with preleukoplakia-like conditions. These results appear to indicate that quids without tobacco are less potent inducers of changes in the

buccal mucosa than quids with tobacco. No dose-effect relationship between changes in the buccal mucosa and light or heavy chewing could be demonstrated.

0979 THE EFFECTS OF BETEL-NUT CHEWING ON THE BUCCAL MUCOSA: A HISTOLOGICAL STUDY. (E.) Lee, K. W. (Inst. Dental Surg., London, England) and C. T. Chin. *Brit J Cancer* 24(3):433-441, 1970.

The histological appearance of leukoplakias from the mouths of West Malaysian betel-nut chewers was examined microscopically. Subjects were Indians and Malays; there were 42 Indians who chewed a quid containing tobacco, and the durations of their chewing habits ranged from 1-50 yr. The remainder of the study population was composed of chewers of quids which did not contain tobacco. An amorphous von Kossa positive layer was seen on the keratin surface in 42 subjects; tobacco was apparently unrelated to this layer. Of 42 tobacco-chewers, 9 showed orthokeratosis, 31 showed parakeratosis, and 12 showed mixed ortho- and parakeratosis. The numbers of non-tobacco-chewers (10 cases) who showed these 3 conditions were resp., 3, 4 and 3. Nine biopsies showed epithelial atypia, all from tobacco-chewing subjects. The average number of mitoses/100 μ length of the basal layer was 0.044 in subjects without leukoplakia and 0.123 in patients with leukoplakia. Long duration of chewing habit seemed to be correlated with relative thinness of buccal epithelium; most chewers whose habit was of 30-40 yr standing had epithelial thicknesses in the 100-250 μ range, while those who had chewed for less than 10 yr were more likely to have epithelia from 450-500 μ in thickness. Eight of the 9 subjects with epithelial atypia had been chewing for more than 10 yr. No relationship between "intensity of habit" (length of time each quid was retained in the mouth of the chewer) and degree of epithelial atrophy was evident. In general, severe histological changes were more likely to be seen in chewers of tobacco-containing quids than in chewers of tobacco-less quids.

0980 TUMORS OF THE URINARY BLADDER: AN ANALYSIS OF THE OCCUPATIONS OF 1030 PATIENTS IN LEEDS, ENGLAND. (E.) Anthony, H. M. (Sch. Med., U. Leeds, England) and G. M. Thomas. *J Nat Cancer Inst* 45(5):879-895, 1970.

The correlation of occupation and development of tumors of the urinary bladder was investigated in a survey of the whole-life occupational histories of 1,030 workers in Leeds, England, with bladder papillomas or carcinomas. Hospital patients with lung cancer and with nonmalignant diseases served as controls. Data on smoking habits of the bladder cancer patients was also compiled, but no clear association between cigarette smoking and the occurrence of bladder tumors could be established. Excesses of bladder tumor patients compared to nonmalignant patients and non-bladder cancer patients were found for workers in the textile and clothing industry, electrical and electronic workers, engineering workers, and service, sport and recreation

workers. Differences in incidence of bladder tumors compared to controls were significant at the 5% level for engineering fitters, engineers, weavers, tailors, and medical workers (mainly nurses). The ratio of textile workers having bladder tumors to controls having bladder tumors was 20:11, and the ratio of clothing workers with tumors to controls with tumors was 19:11. Dye workers were also at risk, with 3 dye workers having bladder cancer. Among clothing workers, tailors and clothes pressers were at especially high risk, the ratio of bladder cancer patients to controls in these 2 occupational categories being 7:0 and 7:2, resp. High risk was usually associated with long-term employment (e.g., employment of more than 20 yr standing). In dye workers, tailors' cutters and hairdressers, tumors appeared at younger ages. The distribution of papillomas and carcinomas in the patients was similar. It was concluded that of the bladder cancer cases observed, the fraction of cancer cases related to occupation may have been in excess of 20%.

- 0981 A CASE OF CHRONIC BERYLLIUM INTOXICATION: PATHOGENIC CONSIDERATIONS AND THE DIAGNOSTIC VALUE OF THE "PATCH TEST". (Fr.) Groetenbriel, C. (Occup. Dis. Med. Council, Brussels, Belgium), W. Van Ganse and J. Oleffe. *Acta Tuberc Pneumol Belg* 61(3-4):363-376, 1970.

A case of chronic beryllium intoxication in a 40-yr-old man who had been exposed to 4 yr of beryllium oxide inhalation while handling fluorescent tubes 15 yr previously is presented. Micronodular opacities in the apical lung region and minor hypertrophic alterations of the right hilar region were found. An immunological mechanism in the pathogenesis of chronic berylliosis and the relationship of beryllium exposure and cancer in humans is discussed. Reference is made to the fact that beryllium containing tobacco is used for smoking in Rhodesia and in Great Britain.

- 0982 ETHMOIDAL CANCER IN WOOD-WORKERS IN THE FURNITURE INDUSTRY. (E.) Macbeth, R. G. (Oxford, England), E. D. Acheson and E. H. Hadfield. *Oto-Rhino-Laryngology* 206:840-842, 1970.

A causal connection between wood dust and adenocarcinoma of the ethmoid sinus was put in evidence. The incidence of ethmoid carcinoma among workers exposed to wood dust in connection with the British furniture manufacturing industry in High Wycombe was investigated. The annual incidence of ethmoid adenocarcinoma in the whole country was 0.00046/1000, while the incidence for this condition among wood workers in the selected town was 0.7/1000. Wood dust deposits in the noses of wood workers were located around the anterior ends of the middle turbinates and in particular on the more roomy side of the nose in the cases of deviated septum.

- 0983 QUALITATIVE CHANGES IN LYMPHOCYTES FOLLOWING BENZENE ABSORPTION. (Ger.) Roth,

L. (2nd Med. Clin. Timisoara, Rumania), P. Turcanu, V. Serban and G. Moise. *Z Ges Inn Med* 25(20):932-935, 1970.

Patients with chronic benzene intoxication in connection with their occupation were investigated for morphological changes in the peripheral blood and the distribution of sinus- and follicular lymphocytes by means of the Stockinger and Kellner staining method. These patients (155) worked in shoe factories where benzene, toluene and acetone were used as solvents, and occasionally the concentration in the atmosphere rose above the permitted threshold. The results of hemograms showed a high incidence of anemias in which slight disturbances in iron metabolism was seen, and which were almost exclusively found in females. In 7 (4.5%) of the tested subjects, massive granulo- and thrombopenias were found. There was also a high incidence of absolute monocytosis (22.5%), and a lesser incidence of changes in the absolute value of lymphocytes (lymphocytosis 7.7%, lymphopenia 5.8%). Large bright lymphoid cells characterized by unusual plasticity of the cytoplasm were observed. Another characteristic feature was the formation of hyperbasophilic lymphocytes. Sixteen cases showed an increase in sinus lymphocytes relative to follicular lymphocytes; of these, 6 showed a complete inversion of the relationship. This inversion of the sinus and follicular lymphocytes was detected in these subjects before any subjective symptoms appeared.

- 0984 BREAST CANCER DURING ORAL CONTRACEPTIVE THERAPY. (E.) Fechner, R. E. (Baylor Coll. Med., Houston, Tex.). *Cancer* 26(6):1204-1211, 1970.

The possibility of an association between the use of oral contraceptives and mammary cancer was explored in 5 women under 35 yr who had been using oral contraceptive pills for periods ranging from 13-60 months. Patients ranged in age from 26-32 yr; all had developed mammary tumors 1.2-3.5 cm in size. In all 5 cases, the invasive neoplasm was a large cell carcinoma of ductal origin; in some cases, remote areas were involved, and metastatic carcinoma involved the axillary lymph nodes in 3 cases. Control cases were composed of mammary cancer cases arising in women who had not used oral contraceptives. Controls included 7 large cell infiltrating ductal carcinomas and 2 intraductal carcinomas without invasion. Four cases showed metastasis to axillary lymph nodes. Controls had a slightly larger average tumor size than test cases, but no gross qualitative differences were seen between the 2 groups.

- 0985 EFFECT OF INTRAUTERINE CONTRACEPTIVE SUTURE ON THE RESPONSE OF RAT UTERUS TO PROLONGED ESTROGEN TREATMENT. (E.) Malaviya, B. (Central Drug Res. Inst., Lucknow, India), J. N. Karkun and A. B. Kar. *Indian J Exp Biol* 8(1):19-21, 1970.

The response of the rat uterus to the insertion of an intrauterine contraceptive suture and to prolonged

rogen administration was investigated. Rats were fitted with a silk suture in 1 uterine horn, and thereafter were given terramycin therapy and i.m. injections of estradiol dipropionate (1 µg/rat/day) for 7 days prior to the insertion in the uterine horn of an intra-uterine contraceptive device (IUCD). After insertion of the IUCD, estradiol dipropionate doses were increased to 2 µg for 3 days, 4 µg for 4 days, and 5 µg for another 136 days. Acid phosphatase activity was markedly greater in the uterine horn containing the IUCD than in the uterine horn containing device (157.5 and 81.8 mg phosphate/100 g/hr in IUCD and control horns, resp.). Glycogen and phospholipid were also increased in the IUCD uterine horn. The endometrium of the control horn was found to be edematous, and exhibited mild polymorphonuclear leukocyte infiltration; cystic hyperplasia was occasionally seen in control horns. Early squamous metaplasia was discernible in places in the control horns. In the uterine horns fitted with IUCD's, polymorphonuclear leukocytic infiltration of the endometrium was more extensive than in control horns, and much of the glandular epithelia and glandular lumina showed massive cystic hyperplasia. Squamous metaplasia of the epithelium was frequent in IUCD-bearing uterine horns. Neoplasia was evident in either control or IUCD uterine horns. Possibly, estrogen treatment and the presence of an IUCD serve to accentuate traumatic reaction in the uterine tissue.

- 0992 FIBROSARCOMA INDUCED BY ALPHA PARTICLE IRRADIATION. (E.) De Estable-Puig, R. F. (Dept. Path., Laval U., Quebec, Canada), J. F. De Estable-Puig and C. Auger. *Virchow Arch Zellpath* 6(4):367-369, 1970.

Production of a fibrosarcoma by subjecting a rat to particulate irradiation is recorded. One rat was exposed to irradiation to the head with α -particles (48 Mev and 1,000 rads/min) produced by a 60 inch cyclotron accelerator. A year after irradiation, a fibrosarcoma was observed on the scalp of the irradiated rat. Microscopically, the tumor cell cytoplasm possessed abundant rough endoplasmic reticulum and well-developed Golgi apparatus. Nuclei were large with irregular invaginations of the nuclear envelope and hypertrophic nucleoli. Many cells had nuclear inclusions in the form of membranes enclosing several sacs or large vesicles filled with a finely granular material of intermediate density.

- 0993 EARLY EFFECTS OF LOCALIZED SINGLE DOSES OF IONIZING RADIATION ON HUMAN BONE MARROW. (E.) Stefani, S. (VA Hosp., Hines, Ill.) and A. Monti. *Acta Radiol* 9(5):449-456, 1970.

The dose effect and effect over time of single doses of ionizing radiation on human bone marrow were investigated. Patients with bronchogenic carcinoma were exposed to daily or weekly doses of 200, 400 or 800 rads in the center of the sternum; radiation was administered at 300 kV at a rate of 48 r/min. The bone marrow of patients exposed to 3 doses of irradiation were examined after 2 days. Cells in the myeloblast-premyelocyte group showed a 25-50% decrease from initial levels; the decrease was more marked at higher doses of radiation. Erythrocytes showed a marked drop which increased with radiation dose, the mean count for these cells reaching a low of 10.8% of the initial count after 800 rads. The relative percentage of lymphocytes rose sharply, the mean being 137.3% for 200 rad and 159.8% for 800 rad. Changes produced by 400 rads of irradiation as a function of time included a relative drop in the myeloblast-premyelocyte group which was evident at 3 hr after exposure, reached its low point after 3 days, and recovered after 6 days. The erythroblasts showed the sharpest relative decrease of any cell component, reaching a 4% of initial cell count at 3 days, and recovering after 6 days. In all cell smears taken 1, 2 and 3 days postirradiation, morphologic abnormalities were observed. Erythroblasts were characterized by an increase in cell size, disruption of the nuclear chromatin pattern, presence of nuclear fragments in the cytoplasm, and double nuclei. No morphologic aberrations were detected in lymphocytes or plasma cells.

- 0994 CLINICAL AND GROSS PATHOLOGICAL FINDINGS IN SWINE RELATIVE TO LATE EFFECTS OF MIXED GAMMA-NEUTRON AND X-IRRADIATION. (E.) Brown, D. G. (Agric. Res. Lab., U. Tennessee, Oak Ridge) and D. F. Johnson. *Radiat Res* 44(2):498-511, 1970.

The effects of mixed gamma-neutron nuclear bomb ir-

radiation and X-irradiation on swine were investigated. Seventy-one swine surviving bomb irradiation in amounts between 15-850 rads were, in some cases, reirradiated with X-rays; pathological and clinical effects were observed for the remainder of the animals' life spans. Irradiated swine weighed on the average 45 kg more than unirradiated controls. Clinical changes were similar in irradiated and control animals except for unilateral atrophy of the musculature in some swine exposed to more than 250 rads. Major causes of death were chronic diseases, the usual clinical syndrome including loss in body wt, debilitation, bacterial infection, and blood changes associated with infections. Mean postirradiation survival times for irradiated swine were 8.3 yr for males and 7 yr for females; survival times for controls were 9 yr for males and 7 yr for females. Mortality rates were higher in irradiated animals through about 7 yr postirradiation, and regression of survival times on dose of irradiation indicated a significant shortening of life of irradiated females. Lesions which were found in significant numbers in irradiated swine and presumably attributable to irradiation were asymmetrical conformation, genital neoplasia usually manifested as leiomyomas of the broad ligaments and uteri, hepatomas, and annular sclerosing adenocarcinomas in the small intestine. Genital tumors appeared earliest in animals exposed to the highest radiation doses. Although genital, hepatic and intestinal tumors developed in all animals, tumors developed earlier in irradiated animals, with controls developing tumors beginning at 9 yr after the beginning of observation and irradiated animals developing tumors beginning at 5-6 yr postirradiation. By 11 yr post-irradiation, 80% of female swine had developed uterine tumors.

- 0995 CARCINOMA OF THE HYPOPHARYNX AFTER IRRADIATION OF THE NECK REGION FOR TUBERCULOSIS OF THE LYMPH NODES. (Ger.) Heilmann, H. P. (Mad. Radiol. Inst., U. Tubingen, Germany). *Strahlentherapie* 140(4):388-391, 1970.

A squamous epithelial carcinoma of the hypopharynx developed in a 69-yr-old woman 50 yr after exposure to roentgen therapy for lymph node tuberculosis in the neck region. The dose monitoring instrument used in 1920 expressed exposure dosages in empirical units which could not be converted to current units. The latency periods for development of malignant tumors through radiation exposure vary in the literature from 3 to 47 yr, with the latency period increasing with lower irradiation dosages.

- 0996 A CASE OF LATE SILICOSIS WITH PLEURAL MESOTHELIOMA. (Fr.) Thzolov, C. (Sofia, Bulgaria) and K. Kolev. *Acta Tuberc Pneumol Belg* 61(3-4):354-362, 1970.

A case of silicosis developed after 14 yr of latency in a 59-yr-old man who spent 10 yr in an uranium mine and was exposed to silicotic dusts and radon radiation is presented. The primary coniotic condition was associated with a later pleural mesothelioma with considerable cellular polymorphism

with the clinical appearance of a lung cancer. Reference is made to the increasing incidence of lung cancer (42%, according to the author's experience) in silicotic patients. The relationship between silicosis and lung cancer is still uncertain. Silicosis may create the favorable conditions for the development of pulmonary neoplasia by triggering the development of pleural mesothelioma in conditions of excessive exposure to pathogenic radiation.

7 ANALYSIS OF ETIOLOGICAL FACTORS OF SQUAMOUS CELL SKIN CANCER OF DIFFERENT LOCATIONS: THE ARM AND THE HAND. (E.) Swanbeck, G. Karolinska Hosp., Stockholm, Sweden) and L. Lästrom. *Acta Dermatovener* 50(5):350-354, 1970.

The distribution of squamous cell carcinoma of the arm and hand was investigated in the Swedish population from reported cases during the period 1958-1965. Of 129 cases of squamous cell carcinoma of the skin on the hand, most cases involved the backs of the hands; 96 of the cases were men and 33 were women. For both sexes the incidence of skin cancer on the hand reached a peak between the ages of 70 and 80 yr (30 male cases and 8 female cases). Specific etiological factors associated with skin cancer on the hands were burn injury (3 cases), X-ray treatment (2 cases), mechanical injury (4 cases) and eczema (3 cases). The fact that more cases of squamous cell skin cancer occurred in outdoor workers than in any other occupational group (40 cases) may indicate that exposure to sunlight is an etiological factor for this condition. Eight cases of skin cancer on the hand had metastasized, 3 of them to the lymph nodes. Cancer of the skin on the arms occurred in 25 cases, of which 11 were men and 14 were women. Age peaks for this condition fell at 55 yr for women and at 65-70 yr for men. No correlation with outdoor work was found for squamous cell skin cancer of the arm; metastases occurred in 11 cases.

98 OCCURRENCE OF ONCOGENOUS X-RAY SUSCEPTIBILITY IN *DROSOPHILA MELANOGASTER* ZYGOTES. (E.) Ghelelovitch, S. (Pasteur Lab., Inst. Radium, Paris, France). *Int J Radiat Biol* 18(4):331-354, 1970.

Specimens of the *cltu* strain of *Drosophila melanogaster* were used to investigate whether irradiation of gametes or irradiation of the fertilized ovum determines the development of tumors in the respective progeny. Males and virgin female flies were exposed to 600 r, 900 r or 1200 r of X-irradiation. Progenies from irradiated females crossed with irradiated males, from irradiated females crossed with nonirradiated males or from nonirradiated females crossed with irradiated males revealed no differences in tumor incidence with respect to progenies from nonirradiated parent gametes. The tumor incidence in progenies from females exposed to 900 r after insemination was compared to 26% in controls, revealing stimulation of tumorigenesis in specimens developed from irradiated zygotes. The environmental con-

ditions within the maternal organism seemed to have no protective effects against X-ray exposure. The lack of tumorigenic effects in progenies originating from male and female gametes irradiated before their fusion and the appearance of such effects following the irradiation of zygotes seem to indicate that the fertilization of the ovum may constitute the event determining the tumor susceptibility to X-irradiation.

0999 STIMULATION OF LEUKEMOGENESIS BY FRACTIONATED X-RAY RADIATION; INHIBITORY ACTION OF HYDROCORTISONE. (Fr.) Mistry, P. B. (Inst. Radium, Paris, France), P. Monnot and J. F. Duplan. *C R Soc Biol* 164(4):697-700, 1970.

The effect of hydrocortisone on AKR or C57BL mice exposed to intermittent irradiation was compared to effects produced by treatment with isogenous bone marrow cells. The animals (AKR and C57BL mice) were irradiated 4 times within 1 wk, the first irradiation being administered at a mean age of 40 days. The injection of hemopoietic cells was administered 24 hr after the final irradiation (8×10^6 to 12×10^7 nucleated cells from isogenic bone marrow). The animals treated with hydrocortisone received 0.5 mg 3 times a week for 3 wk (AKR mice) and for 4 wk (C57BL), commencing immediately following the last irradiation. The incidence and latency of leukemias in the normal AKR mice was 90% at the age of 323 days. After fractionated radiation, all died of leukemia at the mean age of 205 days. Under treatment of hydrocortisone, the incidence of leukemias was 95% and latency was 288 days. In the C57BL mice, fractionated irradiation increased the incidence from 2.5 to 81% and decreased the latency from 612 to 261 days. Cortisone administration caused an incidence of 39% and latency of 297 days. The incidence of leukemia decreased to 10% and the latency period increased to 528 days after treatment with isogenous bone marrow cells. This specific treatment produced better results in C57BL mice than in AKR mice. Hydrocortisone exhibited inhibitory effects on leukemogenesis in both investigated mouse lines.

1000 BONE CANCERS INDUCED BY ^{224}Ra (Th X) IN CHILDREN AND ADULTS. (E.) Spiess, H. (Child. Polyclin., U. Munich, Germany) and C. W. Mays. *Health Phys* 19(6):713-729, 1970.

The induction of bone sarcomas by therapeutic exposure to ^{224}Ra for the treatment of tuberculosis, ankylosing spondylitis, and other diseases was investigated. Subjects included 217 children and 708 adults; the average skeletal dose of radium was 140 $\mu\text{C}/1000$ esE, which amounted to an average dose in rads to the marrow-free skeleton of 0.6 rads for children aged 1-15 yr, 0.4 rads for those aged 16-20 yr, and 0.2 rads for adults. Forty-nine patients developed bone sarcomas; the lowest skeletal dose of radium among patients developing tumors was 90 rads. Fifteen percent of children and 1.4% of adults developed bone sarcomas, yielding incidence rates for tumor development/100 rads of 1.38% for children and 0.69% for adults. In 19 cases, 5-11 yr elapsed be-

tween radium exposure and appearance of sarcomas. Radium induction of sarcomas was equally efficient in males and females and in patients with and without bone disease at the time of radiation. Twenty-one soft-tissue tumors developed in the study population, but none was thought to be related to radium exposure.

- 1001 ACUTE RADIATION INJURY IN NEONATALLY THYMECTOMIZED GERM-FREE MICE: HEMATOPOIETIC AND MORPHOLOGIC CONSEQUENCES. (E.) Doughty, W. E. (Sch. Med. U. New Mexico, Albuquerque), R. E. Anderson, J. L. Howarth and S. Tokuda. *Arch Path* 91(2):119-126, 1971.

The hematologic and morphologic consequence of a single whole body exposure to 700 rads of cobalt 60 γ -rays in neonatally thymectomized germ-free mice and the role of the thymic-dependent lymphoid reserve in subsequent recovery were studied. At 6 wk of age, 64 intact and 112 thymectomized mice were exposed to γ -irradiation; on days 4, 8, 12, 20, 24, 28, 32, 40 and 150 postirradiation, 4 mice from each group were bled and sections were prepared from their organs. Four intact and 4 thymectomized non-irradiated mice were similarly treated at 6 and 27 wk of age as controls. The cumulative mortality was 9.3% and 18.3% in the intact-irradiated and thymectomized-irradiated groups, resp. Following radiation, total leukocytes dropped to less than 500/mm³ in both groups, recovered, and exceeded control levels by 20-24 days postexposure; this peak was followed by another decrease and recovery cycle peaking at day 40. The absolute lymphocyte count variation was directly related to the total leukocyte count; mean hematocrit values decreased transiently postirradiation. Spleen wt decreased to half of control values at 10 day postirradiation and more than doubled at 20-24 days following exposure before returning to control values at 30 days. Hematopoietic colony forming unit proliferation in spleen and bone marrow more or less followed the changes in spleen wt. The thymus gland of the intact irradiated mice underwent hyperplasia initially, but by 20 days postexposure had less cellularity than control animals. Microscopic abnormalities were not found in the heart, lung, gonads, and liver of either group. The hematological response to radiation injury appears to be modified by thymectomy, favoring the nonoperated over the thymectomized mice.

- 1002 CHROMOSOME ABERRATIONS INDUCED BY X-RAY THERAPY AND MYXOVIRUS INFECTION IN HUMAN PERIPHERAL LEUKOCYTES. (E.) Stenman, S. (3rd Dept. Path., U. Helsinki, Finland), S. Nordling, L. R. Holsto and E. Saksela. *Mutat Res* 10(6):607-616, 1970.

The induction of chromosome aberrations by X-irradiation and myxovirus infection was investigated in phytohemagglutinin-stimulated lymphocytes from 29 women who had undergone radical surgery for cancer of the breast. Patients were given 250 kV of X-irradiation in 4 areas near the left breast and shoulder. Correlations between X-ray dose and chromosome aberration for these patients' lympho-

cytes, and for lymphocytes from irradiated patients with myxovirus infection were studied. Dicentric and rings increased in incidence as X-irradiation doses increased, with the number of aberrations/cell approaching 0.2 as irradiation doses increased from 1000-10,000 rads; the equation for the yield of dicentric and rings was $y = 0.0086 + 1.53 (\pm 0.15) \times 10^{-5} D$, where D is equal to the accumulated skin dose of X-ray in rads. The incidence of fragments/cell was similar, and corresponded to the equation $y = 0.022 + 1.68 (\pm 0.17) \times 10^{-5} D$. The percentage of all damaged cells peaked at 22% between 6000-7000 rads, and dwindled at doses exceeding this. Irradiation did not affect the numbers of aneuploid cells, nor did it markedly decrease the percentage of chromatid-damaged cells. Lymphocytes from irradiated patients were infected with Newcastle disease virus, Sendai virus, measles virus, and mumps virus, and controls were given normal allantoic fluid. The frequency of chromatid-type aberrations in controls increased after irradiation, while none of the viruses caused significant increases. Virus treatment did not significantly affect the frequency of chromosome-type aberrations. Radiation therapy increased the frequency of aneuploid cells from 5% before therapy to 15% at the end of therapy for all virus-infected cells; percentages of tetraploid cells increased with therapy from 0.4-0.6%. In all dose ranges of X-irradiation, the distribution of cells with chromosome breaks deviated from a Poisson distribution unless the number of undamaged cells present in excess was omitted from calculations. Almost 30% of circulating lymphocytes appear to have been exposed to irradiation by the area-irradiation method used.

- 1003 SPECULATED RISK TO BONE AND LIVER FROM ²³⁹Pu. (E.) Mays, C. W. (Radiobiol. Div. U. Utah, Salt Lake City), G. N. Taylor, W. S. S. Jee and T. F. Dougherty. *Health Phys* 19(5):601-610, 1970.

The risk of developing bone and liver cancer following exposure to ²³⁹plutonium was estimated speculatively on 3 models of the incidence of tumor development extrapolated from available human and animal dose-response data. The threshold model of risk of bone and liver tumors was developed from data on tumor incidence in humans exposed to radium, while the dose-rate model and the lifespan dose model were developed from data on tumor incidence in dogs exposed to plutonium. The acceptable body burden of ²³⁹plutonium in radiation workers is 0.04 μ C. Plutonium reaching the circulatory system from occupational exposure is deposited approximately equally in bone and liver. Fifty-yr doses to man for a constant dose of 0.02 μ C of ²³⁹plutonium in bone and liver were calculated as 14 and 57 rads. From these doses the probability of radiation-induced tumors in the liver and bone with the threshold model are 0% for both bone and liver. The probability of tumor induction in these organs with the dose-rate model are 1% for bone and 2% for liver. The probability of tumor development following ²³⁹plutonium exposure for bone and liver with the lifespan model are 5% and 10%, resp. Hazards to the lung from inhaled

autonium and hazards for tumorigenesis at exposed wound-puncture sites were not estimated. The risks calculated referred to adult ^{239}Pu exposure only.

- 004 DIFFUSE PLEURAL MESOTHELIOMA: A CLINICAL AND PATHOLOGICAL STUDY. (E.) Roberts, G. (Southern Gen. Hosp., Glasgow, Scotland). *Brit Dis Chest* 64(4):201-211, 1970.

Clinical and pathological features of cases of diffuse pleural mesothelioma were investigated in a Glasgow hospital. The hospital served a population which was mainly employed in shipyards, and which incurred a high risk of asbestos exposure. Over 18 yr, 20 cases of diffuse pleural mesothelioma were found among 6406 necropsies, with 15 cases reported from the second 9-yr period. Of these cases, 19 were middle-aged or elderly patients, and 16 were men. Six of the male patients had some occupational connection with the shipbuilding industry. In 18 cases, presenting symptoms included dyspnea and chest pain; 15 cases showed evidence of pleural effusion at the time of admittance to the hospital. Seventeen of the patients died within 12 months of the onset of symptoms. In all cases, pleural involvement by the tumor was extensive, partially or completely obliterating the pleural cavity. In 16 cases, the mesothelioma was unilateral, the lung parenchyma was infiltrated. The mediastinal lymph nodes were infiltrated in 9 cases, the pericardium in 6 cases; spread outside the thorax was found in 6 cases. Distant metastases were not common; 11 tumors showed an epithelial pattern and 6 were mesenchymal. Asbestos bodies were found in the lungs of 18 of the cases; there was histological evidence of asbestosis in 13 cases.

- 005 CHROMOSOME ABERRATIONS IN SWINE LEUKOCYTES AFTER *IN VIVO* OR *IN VITRO* EXPOSURE TO 14 MeV NEUTRONS. (E.) McFee, A. F. (U. Tennessee-Atomic Energy Comm. Agric. Res. Lab., Oak Ridge), M. W. Banner and M. N. Sherrill. *Radiat Res* 44(2):512-522, 1970.

The efficacy of irradiation with MeV neutrons in causing chromosome aberrations in pig leukocytes irradiated *in vivo* and *in vitro* was investigated. Female pigs, averaging 206 pounds in wt, were subjected to whole-body neutron irradiation, and venous blood samples were irradiated simultaneously. Leukocyte cultures were established from control, *in vivo*-irradiated pigs and *in vitro*-irradiated cells, and chromosome aberrations, including deletions, dicentric, rings, and breaks, were examined in each culture. Neutron irradiation was more effective in producing chromosome breaks in *in vitro*-irradiated cells than in *in vivo*-irradiated cells. Breaks in *in vitro*-irradiated cultures averaged 2.4 total breaks/cell at 200 rads, while at the same dose *in vivo*-irradiated cells averaged 0.7 breaks/cell. At 300 rads, chromosome deletions averaged 1.4/cell in *in vitro*-irradiated cells, and 0.9 in *in vivo*-irradiated cells. At 350 rads, dicentric and rings averaged 0.5/cell in *in vitro*-irradiated cells and 0.2 in *in vivo*-irradiated cells. These findings

permit the derivation of formulae for the prediction of chromosome aberrations in *in vitro*- and *in vivo*-irradiated cells. The prediction formulas are, for *in vitro* breaks/cell, $Y = 0.00068D + 0.47$; for *in vivo* breaks/cell, $Y = 0.0068D - 0.539$, where D represents the neutron dose administered to a blood sample or measured in air at the recipient animal's midline.

- 1006 NATURAL THORIUM IN HUMAN BONE. (E.) Lucas, H. F. Jr. (Argonne Natl. Lab., Ill.), D. N. Edgington and F. Markun. *Health Phys* 19(6):739-742, 1970.

The thorium content in the bone matter of normal humans was determined in a survey of the ^{232}Th content in the rib bones from 38 individuals. The concentrations of ^{232}Th ranged from less than 0.1-72 ng/g bone ash. The high figure was markedly higher than the next highest value for ^{232}Th concentration, 42.4 ng/g, and was recorded from a man who had had a 40-yr occupational exposure to thorium dust. Thorium concentrations increased with age, with concentrations of 2.5 ng/g for 20-yr-olds, compared to concentrations of 10 ng/g for 70-yr-olds. The increase of ^{232}Th concentration with age fitted the equation: $Y = (0.16 \pm 0.02)T$, where Y = the ^{232}Th concentration in ng/g bone ash and T = the age in yr. Smokers were thought to have increased ^{232}Th concentrations compared to nonsmokers.

- 1007 HISTOPATHOLOGY OF LATE LOCAL RADIOLESIONS IN THE GOAT BRAIN. (E.) Andersson, B. (Gustav Werner Inst., Uppsala, Sweden), B. Larsson, L. Leksell, W. Mair, B. Rexed, P. Sourander and J. Wennerstrand. *Acta Radiol* 9(5):385-394, 1970.

Histopathological examinations were made on deep-brain lesions produced in goats by cross-fire irradiation with 185 MeV proton-beams. Adult goats were exposed to proton irradiation in doses of 15,000 rads (1 animal) or 20,000 rads (5 animals) and killed 1½-4 yr later. Lesions were located in the thalamus, optic chiasma, optic tract, pallidum and internal capsule. Following the acute degeneration produced by irradiation, lesions appeared to progress in 3 phases. At 3-4 wk post-irradiation, necrosis and inflammatory reactions were observed; thereafter, progress of the lesions was characterized by resorption of cellular debris and by the beginning of glial scar formation. This phase was marked by astrocyte proliferation around the necrotic area, and by occasional giant cells, formation of new capillaries, and round cell proliferation. The late stage was marked by prominent glial scar formation, lesions showing no inflammatory reaction, no giant cells, no teleangiectasis, and no hemorrhage. No evidence of cellular elements resembling neoplastic development was found, and it appeared that no untoward late developments followed proton-irradiation in the goat brain.

- 1008 CHROMOSOME CONSTITUTION AND ITS BEARING ON THE CHROMOSOMAL RADIOSENSITIVITY IN MAN. (E.) Sasaki, M. S. (Inst. Med. Genet., Tokyo,

Japan), A. Tonomura and S. Matsubara. *Mutat Res* 10(6):617-633, 1970.

The relation between chromosome constitution and chromosomal radiosensitivity of lymphocytes was studied by analyzing the types and frequencies of radiation-induced (γ -rays, 160 r) chromosome aberrations in blood samples from 49 patients with various types of inborn chromosome abnormalities. Chromosomal radiosensitivity was consistently higher in trisomic cells (whole or part of a chromosome) than in normal cells but was not affected by monosomic conditions, reciprocal translocation, or inversion. An age dependency for radiosensitivity was observed in the level of exchange aberrations which were elevated in the neonatal stage but dropped to the expected level of adults within the first 1 or 2 years, but the level of deletions was not dependent on either chromosomal constitution or the age of the subject. The increased chromosomal radiosensitivity in trisomic cells and the susceptibility of the affected subjects to neoplasia suggest that trisomic cells are particularly cancer-prone and that the illegitimate repair of chromosome damage (intrinsic to trisomic cells) may be a common pathway in carcinogenesis.

1009 THE ULTRASTRUCTURE OF THE LUNG OF MICE EXPOSED TO A SUPRA-LETHAL DOSE OF IONIZING RADIATION ON THE THORAX. (E.) Maisin, J. R. (Dept. Radiobiol., C. E. N./S. C. K., Mol, Belgium). *Radiat Res* 44(2):545-564, 1970.

Electron microscope examinations were conducted on the lungs of mice which had been exposed to supra-lethal doses of ionizing radiation to the thorax. Mice were given doses of 2000 rads of X-irradiation to the whole chest or to the right hemithorax, and ultrastructural studies were carried out 0-15 months thereafter. Three to 6 hr after exposure, lesions were limited to certain foci; however, all types of lung cells showed changes, and the interstitial tissue was dissociated by edema. At this early stage, the cytoplasm of granular pneumocytes showed dilation of the endoplasmic reticulum. Most mice irradiated at the whole chest died between 2-7 months after irradiation; the lungs showed accumulation of myelin-like figures, cell debris, and fibrin-like material in the lumen of the alveoli. Increases in size and number of granular pneumocytes, severe lesions in the capillaries, and an increase in the number of macrophages, neutrophilic leukocytes and plasmocytes also characterized this intermediate stage. Nuclei of granular pneumocytes at this stage were hypertrophied and irregular. Collagen fibers and elastic fibers, however, were only slightly more abundant during the intermediate stage than normally. Mice which survived the intermediate phase showed extensive sclerosis and hyalinization of the alveolar septa associated with lesions in the capillaries. In this final or chronic stage, granular pneumocytes appeared to be normal but were largely diminished in number. Lesions in the capillaries seemed to play an important role in the development of ultrastructural changes in the lung epithelium and in interstitial tissue; however, it is difficult

to assess the contributions to the total picture of ultrastructural change of direct radiation damage to cells and of indirect damage by impaired blood circulation.

1010 BREAST CANCER AND CALCIFIED FATTY TISSUE TRANSPLANTS AFTER PLASTIC SURGERY FOR BREAST ENLARGEMENT. (Ger.) Hermanutz, D. (Radiol. Clin. U. Bonn, Germany) and R. Müller. *Fortschr Roentgenstr* 113(4):530-533, 1970.

Calcium deposits are often seen in the breast both with malignant and benign tumors and may be detected by radiological technique. Malignancy is characterized by a "granular" appearance of such calcification and is found in about 1/3 of the cases. The case of a 30-yr-old patient with palpable nodes in the right breast and a well-defined node in the right axilla, is described. Microcalcifications were observed in X-rays films; additional evidence of carcinoma was the presence of dilated vessels in the tumor area, a characteristic of this type of carcinoma. Histologically, the tissue revealed a predominantly solid, partially adenoid carcinoma in sections of the lactiferous ducts and fine granular calcified foci of necrotic cell bands in the tumor. At the age of 24 yr the patient had received subcutaneous fat tissue transplantation in both breasts to correct a hypoplasia. The mother and sister of this patient had died of carcinoma, the former of mammary carcinoma. The question whether plastic breast surgery would increase the incidence of mammary gland carcinoma is raised.

1011 PROLIFERATIVE ACTIVITY OF THE STEM CELLS IN THE BONE-MARROW OF MICE AFTER SINGLE AND MULTIPLE IRRADIATIONS: TOTAL-OR PARTIAL-BODY EXPOSURE. (E.) Croizat, H. (Inst. Gustave-Roussy, Villejuif, France), E. Frindel and M. Tubiana. *Int J Radiat Biol* 18(4):347-358, 1970.

Female mice were given single doses of 150 rads of X-irradiation to the whole body (40 mice) or a similar dose with the right leg shielded (249 mice); mice in another group were subjected to 1000 rads of whole-body irradiation. In the iterated X-irradiation experiments, 60 mice were given subtotal irradiation daily (150 rads for 2-11 irradiation sessions in total); a comparison group was given 1000 rads of whole-body irradiation. Numbers of stem cells in the bone marrow of irradiated mice were determined, as were the proportions of stem cells synthesizing DNA. Mice receiving a single dose of radiation showed a transient decrease of stem cells in the shielded marrow followed by a rise to 125% of the initial number of stem cells from 7-48 hr after irradiation. The proportion of stem cells synthesizing DNA remained at 50% of normal 24 hr after irradiation. In irradiated leg bone marrow, the number of stem cells decreased rapidly to 50% of control and remained at this level for the next 24 hr. The proportion of cells in DNA synthesis increased sharply immediately after irradiation, then fell off to 12% of controls before rising again to 50% at 24 hr. After whole body

radiation, the number of stem cells fell to 55% of normal and changed little thereafter. By 24 hr post-radiation the proportion of stem cells in DNA synthesis was slightly higher than unirradiated controls. In repeatedly irradiated mice the number of stem cells in the marrow of the protected leg decreased steadily and reached 10% of normal values at the end of the course of irradiation. In repeatedly irradiated areas the number of stem cells dropped during the first days to 0.5% of the initial value and increased slowly thereafter to 1.5% of initial values at the end of the irradiation course. In protected marrow after the second irradiation session the number of cells synthesizing DNA was twice the initial number, later decreasing to 2% of initial numbers. However, the proportion of cells in DNA synthesis remained higher than in controls. The depletion of protected bone marrow stem cells following irradiation and their subsequent recovery is apparently due to migrating hematopoietic cells between irradiated cells and protected regions.

1012 DISTRIBUTION OF ^{239}Pu IN THE BONE MARROW AND ON THE ENDOSTEAL SURFACE OF THE FEMUR OF ADULT RABBITS FOLLOWING INJECTION OF $^{239}\text{Pu}(\text{NO}_3)_4$. (E.) Bleaney, B. (Churchill Hosp., Oxford, England) and J. Vaughan. *Brit J Radiol* 44(517):67-73, 1971.

The distribution in bone tissue of plutonium following a dose of $^{239}\text{Pu}(\text{NO}_3)_4$ was studied in rabbits. Rabbits were given either 2.62, 1.24, 1.25, or 2.5 $\mu\text{C/kg}$ of $^{239}\text{Pu}(\text{NO}_3)_4$. In the 1.25 μC dosage group, the dose was administered i.v., while in other dosage groups the dose was administered i.m. At all dose levels, the distribution of plutonium given i.m. was diffuse for the first 35 days postinjection; aggregates of plutonium began to appear at 112 days. In rabbits given 1.24 μC doses, the plutonium level at the injection site dropped more rapidly than in the group given 2.62 μC , and, as a consequence, radiation doses in the marrow were higher in shorter times in the lower dosage group. Estimation of the amount of plutonium in cells at the surface of the marrow showed that the amount increased by a factor of 5 between 8-112 days after i.m. injection. More plutonium was found in the endosteal cells after i.m. injection of 2.5 μC (50% of the total plutonium was retained in the endosteal area in the i.m. group as opposed to 30-44% in the i.v. groups). In cells of the endosteal surface, 40% of the total plutonium was present in the endosteal cells themselves, and 60% was located on the mineral or matrix of the bone surface free of cells. Plutonium was also found in the osteogenic cells themselves, a finding which may account for the virulent carcinogenicity of plutonium.

1013 TOXICITY OF INHALED ^{90}Sr FUSED CLAY IN BEAGLE DOGS: I. (E.) Barnes, J. E. (no affil), B. B. Boecker, C. H. Hobbs, R. K. Jones, G. M. Kanapilly, J. L. Mauderly, R. O. McClellan and J. A. Pickrell. *Fission Products Inhalation Program Annual Report* 1969-1970: 188-196, 1970.

The retention of Sr^{90} fused clay in the body of beagle dogs 8-256 days after inhalation of aerosol Sr^{90} fused clay was investigated. Initial lung burdens of Sr^{90} ranged from 30-680 $\mu\text{C/kg}$. Sixty-

four percent of the aerosol inhaled was deposited in the dog; of that amount deposited in the dogs' body, 57% was found in the pulmonary region. The percentage of Sr^{90} retained in the bodies of dogs declined with time; by the end of the first day after inhalation, percentages of retained Sr^{90} dropped 100-40% thereafter leveling off at 30% and 28% retention by days 180 and 265, resp. The rapid initial loss was thought to represent the rapid clearance of the upper respiratory tract which occurred with a half-time of about 0.35 days. The gradual phase of decline in retained Sr^{90} is consistent with a half-life of 420 days for Sr^{90} , with a biological half-life of 440 days. By 512 days after inhalation, 89% of the retained Sr^{90} was located in the lungs, 6% in the skeleton and 3% in the tracheobronchial lymph nodes. Sr^{90} retention in other organs was negligible; however, activity in the liver comprised a small percentage of the total body burden of Sr^{90} until 256 days after inhalation. Although no dogs died of Sr^{90} inhalation, those dogs given the largest doses showed signs of radiation pneumonitis when their cumulative radiation doses reached 40,000-47,000 rads in the lungs.

1014 TOXICITY OF INHALED $^{90}\text{SrCl}_2$ IN BEAGLE DOGS: IV. (E.) Boecker, B. B. (no affil), T. L. Chiffelle, C. H. Hobbs, R. K. Jones, R. O. McClellan, J. A. Pickrell and H. C. Redman. *Fission Product Inhalation Program Annual Report* 1969-1970 :123-127, 1970.

The toxic and carcinogenic effects of ^{90}Sr , inhaled as an aerosol of $^{90}\text{SrCl}_2$ by beagle dogs, was investigated. At 14 days after inhalation of the compound, mean body burdens of ^{90}Sr for the dogs ranged from 1.4-75 μC of $^{90}\text{Sr/kg}$. Dogs with 14-day body burdens of ^{90}Sr of 50-100 $\mu\text{C/kg}$ had markedly shorter survival periods than dogs with lower body burdens. Nineteen dogs died or were killed between 585-1787 days postinhalation; of these dogs, 7 had angiosarcomas, 3 had fibrosarcomas, 5 had osteosarcomas, 1 had osteochondrosarcoma, 1 had osteochondrofibrosarcoma, 1 had leukemia, 1 had an epileptic seizure, and 1 had cerebellar hemorrhage. The cumulative radiation doses to the skeletons of the dogs in this group at death from the inhaled ^{90}Sr ranged from 4000-22,000 rads.

1015 TOXICITY OF INHALED $^{144}\text{CeCl}_3$ IN BEAGLE DOGS: IV. (E.) Boecker, B. B. (no affil), S. A. Benjamin, T. L. Chiffelle, R. K. Jones, C. H. Hobbs, R. O. McClellan, J. A. Pickrell and H. C. Redman. *Fission Products Inhalation Program Annual Report* 1969-1970 :128-136, 1970.

The toxic effects of ^{144}Ce , inhaled as $^{144}\text{CeCl}_3$, was investigated in beagle dogs. Fifty-five dogs which inhaled the compound were placed in a longevity study for lifelong observations. The ^{144}Ce burden of these dogs at 14 days after inhaling $^{144}\text{CeCl}_3$ ranged from 0 $\mu\text{C/kg}$ for controls not inhaling the compound to a high of 230 $\mu\text{C/kg}$. It was found that inhaled ^{144}Ce deposited in the lung was rapidly transferred to liver and skeleton. By 450 days after inhalation,

the lung contained less than 1% of the initial lung burden of ^{144}Ce , while the liver and skeleton contained 50% and 30%, resp., of the initial lung burden. Seventeen dogs from the 120 and 230 $\mu\text{C/kg}$ ^{144}Ce body burden groups died by 510 days after inhalation. Of these, 3 had hepatic necrosis, 1 had pulmonary fibrosis, 1 had marrow aplasia and 2 had tumors. One of the tumor-bearing dogs had an osteogenic sarcoma, and 1 had squamous cell carcinoma of the maxilla and a small papillary adenoma of the lung.

1016 RADIOPATHOLOGY OF AMERICUM 241: I. DISTRIBUTION OF AMERICUM IN ADULT MICE. (E.)
Hammarstrom, L. (Roy. Vetr. Coll., Stockholm, Sweden) and A. Nilsson. *Acta Radiol* 9(5):433-442, 1970.

- 7 VIRUS-LIKE PARTICLES IN RHABDOMYOSARCOMA WITH EPIDERMODYSPLASIA VERRUCIFORMIS. (E.) Imoto, T. (Fukayama Natl. Hosp., Hiroshima, Japan), Y. Yabe and S. Ohmori. *Dermatologica* 141:309-314, 1970.

Rhabdomyosarcoma located on the chest wall of a 4-yr-old man who also had squamous cell carcinoma of the leg and metastasis to the right inguinal lymph node was found to contain virus-like particles. The rhabdomyosarcoma exhibited epidermodysplasia verruciformis. Under the light microscope, the tumor showed pleomorphism, and numerous giant cells, often having bizarre nuclei and vacuolated cytoplasm. Under the electron microscope, virus-like particles were demonstrated; the particles ranged 90-110 nm in diameter, with nuclei of about 50 nm. The particles were apparently C-type, and appeared in both cytoplasm and extracellular spaces. Four rhabdomyosarcomas without epidermodysplasia verruciformis were examined and found to lack virus-like particles.

- 8 VIRUS-LIKE PARTICLES IN CULTURED HUMAN GLIOMA. (E.) Tani, E. (Kyoto U. Med. Sch., Japan), J. Takeuchi and T. Ametani. *Acta Neuropath* 16(3):266-270, 1970.

Segments of the tumor mass cultured for 30 days and surgical specimens from a patient with glioma were examined by light and electron microscopy. The tumor cells exhibited a pleomorphism with elongated nuclei and scant cytoplasm. Nucleoli contained annular components and glycogen particles were scattered throughout the cytoplasm. Round virus-like particles (100-110 mμ in diameter) were observed in the extracellular site of the cultured tumor cells. The particles had a homogeneous dense core (60-70 mμ in diameter) and were surrounded by a limiting membrane with no spikes or spicules. The virus-like particles suggested a mature type C virus although budding at the cell membrane (characteristic of immature type C virus) was not observed.

- 9 VIRUS-INDUCED POLYKARYOCYTOSIS AND THE MECHANISM OF CELL FUSION. (E.). Poste, L. (Roy. Postgrad. Med. Sch., London, England). *Advances Virus Res* 16:303-356, 1970.

Aspects of the process of polykaryocytosis and cell fusion are discussed with emphasis placed on viral-induced phenomenon. Time-lapse cinematographic studies, electron microscopy, cell marker and nuclear count techniques and studies of single cells are given as evidence of viral polykaryocytes being formed by cell fusion. Differences in the ability of cells to fuse following virus infection are striking with a higher fusion capacity exhibited by malignant and established cell lines and "young" cells and is ultimately dependent upon the genetic constitution of the virus modified by culture media and techniques. Viruses which induce cell fusion cause a reduction in the thickness of the cell coat to below 35 Å by release of lysosomal

hydrolases, a process which can be inhibited by stabilizing agents which also prevent cell fusion. The membrane fusion process is energy-dependent, involving fundamental reorganization of membrane structure. There is little detailed knowledge of the biochemical and molecular events involved in the process. (334 references)

- 1020 EFFECT OF NEOCARZINOSTATIN ON THE CULTURED BURKITT LYMPHOMA CELLS, WITH PARTICULAR REFERENCE TO THE ENHANCEMENT OF PRODUCTION OF EPSTEIN-BARR VIRUS. (E.) Sairenji, T. (Sch. Dent., Tohoku U., Sendai, Japan), J. Yamaguchi, S. Katagiri and Y. Hinuma. *Cann* 61(5):451-460, 1970.

The relationship between Epstein-Barr virus synthesis and the growth of host cells harboring the virus was studied. Neocarzinostatin, in amounts of 1 or 10 μg/ml, was added to cultures of Burkitt lymphoma cells, and the effect on cell division and on the presence and activity of virus in the cells was observed. Treatment with 1 μg/ml of neocarzinostatin inhibited cell growth, with the cell count decreasing from 10^5 /ml at incubation with the antibiotic to $10^{4.8}$ /ml 5 days later. Incubation with neocarzinostatin induced development of giant cells, which began to appear 24 hr after introduction of the compound. Immunofluorescence-positive cells were more frequent in neocarzinostatin-treated cultures than in controls, with the positive cells constituting 28% of cultures 5 days after incubation with 1 μg/ml neocarzinostatin as compared with 11% positive cells in control cultures at that time. This indicated that the percentage of Epstein-Barr virus-bearing cells was higher in neocarzinostatin-treated than in untreated cultures. Counts of virus particles in cultures treated with neocarzinostatin and in control cultures showed that the production of virus particles in treated cultures was higher than in untreated cultures; cell-associated virus particles numbered 8×10^7 /culture at the commencement of neocarzinostatin incubation and 2.8×10^8 after 8 days of incubation. Virus particles in treated and untreated cultures were morphologically similar. The number of cells incorporating ^3H -thymidine was higher in fluorescent (virus-bearing) cells in the presence of neocarzinostatin than in non-fluorescent cells. Apparently, neocarzinostatin inhibits cell division but not viral DNA synthesis or the formation of viral particles in cells; the compound also appears to reduce the synthesis of host cellular DNA.

- 1021 EPSTEIN-BARR VIRAL ANTIGEN IN SINGLE CELL CLONES OF TWO HUMAN LEUKOCYTIC LINES. (E.) Miller, M. H. (Child. Hosp. Med. Ctr., Boston, Mass.), D. Stitt and G. Miller. *J Virol* 6(5):699-701, 1970.

Single cell clones derived from 2 cell lines were assayed for Epstein-Barr virus (EBV) antigen. The cell lines, LS-B and EB₃, were established from the peripheral blood of a child with acute leukemia and from a Burkitt lymphoma tumor. Clones were established from single cells from each of these lines

in the presence of human placental cell feeder layer. All 10 of the clones derived from LS-B cells contained EBV antigen; usually no more than 0.1-0.2% of the cells contained antigen. All EB₃ clones also contained viral antigen, about 1% of cells showing antigen-positive reactions. These findings appear to suggest that the EBV genome is associated with more cells than demonstrate EBV antigen.

- 1022 IMMUNOSUPPRESSION BY LEUKEMIA VIRUSES:
IV. EFFECT OF FRIEND LEUKEMIA VIRUS ON
ANTIBODY-PRECURSORS AS ASSESSED BY CELL TRANSFER
STUDIES. (E.) Ceglowski, W. S. (Temple U. Sch. Med.,
Philadelphia, Pa.) and H. Friedman. *J Immunol*
105(6):1406-1415, 1970.

Immunosuppression induced by leukemogenic Friend virus infected mice spleens were studied for antibody-precursor cells through indirect cell transfer using drug-treated inbred female BALB/c mice as recipients, in an attempt to delineate the mechanism involved. Transfer of cells from normal mice, followed by immunization with RBC, resulted in the appearance of increasing numbers of plaque-forming cells reaching a peak of approximately 5000 at 9 days after cell transfer; drug-treated mice showed similar kinetics of plaque-forming cell appearance but which peaked at a level 50% lower than in control animals. Earliest rise in the appearance of antibody foci occurred on day 3, increasing till day 6 and then declining with consistently fewer foci appearing in spleens of recipient mice given spleen cells from infected donor animals, with the lowest number occurring when the time interval between infection and cell transfer was longest. Although a direct effect of a leukemia virus on antibody-forming cells or their precursors is still speculative, it has been proposed that these viruses may suppress immunity by interfering with specific cellular components of the immune system.

- 1023 STUDIES ON THE INFECTIVITY AND CYTOPATHOLOGY OF EPSTEIN-BARR VIRUS IN HUMAN LYMPHOBLASTOID CELLS. (E.) Durr, F. E. (Dept. Virol. Cancer Res., Pfizer Inc., Maywood, N.J.), J. H. Monroe, R. Schmitter, K. A. Traul and Y. Hirshaut. *Int J Cancer* 6(3):436-449, 1970.

The infective capacity and cytopathic effect of Epstein-Barr virus (EBV) in cultures of human lymphoblastoid cells was investigated. EBV concentrates were prepared from virus-positive Burkitt lymphoma cells (P-3J strain) and from a clone of these cells (HRLK cells). Cell cultures were prepared from normal human peripheral blood, maxillary tumors from Burkitt lymphoma cases, and blood from acute myelogenous leukemia cases. Indicator cells from these cultures were exposed to 0.5-1.0 ml of virus concentrate. All types of culture were successfully infected by the virus, and 2 general types of cytopathic effect were observed. In 1 case, a cytopathic effect was produced which brought about 98% cell death in 4 days. HRLK cells produced the most marked cytopathic effects, usually inducing acute cytopathic effects within 16-72 hr postinfection.

The acute cytopathic effect was characterized by cell swelling, progressive degeneration, and progressive polykaryocyte formation. A less severe cytopathic effect included minimal cell swelling, followed by either the establishment of a carrier culture or of a culture in which virus eventually disappeared. Non-enveloped herpesvirus-type particles were detected in the nuclei of changed cells as early as 16 hr postinfection; virus particles with envelopes could be found in the cytoplasm at a later point. Cells from Burkitt lymphoma and acute myelogenous leukemia showed a less acute cytopathic effect and fewer virus-antigen containing cells than did cells from normal blood. Human sera containing antibodies which reacted with the EBV envelope neutralized infectivity.

- 1024 EPSTEIN-BARR VIRUS IN BURKITT'S LYMPHOMA AND NASOPHARYNGEAL CARCINOMA. (E.) Gunven, P. (Karolinska Inst., Stockholm, Sweden), G. Klein, G. Henle, W. Henle and W. Clifford. *Nature* 228(5276):1053-1056, 1970.

Anti-membrane antigen and anti-Epstein-Barr-viral capsid antigen antibody levels in 96 Burkitt's lymphoma patients in different disease stages were compared with their healthy blood relatives and Africans with chronic tonsillitis. Elevated levels of anti-viral capsid antigen antibody were found in all Burkitt's lymphoma patients compared to 2 groups of healthy relatives and the tonsillitis group; no significant differences were found according to age and sex. A significant elevation of anti-membrane antibody was also noted; a slightly lower mean was seen in patients in remission for 1 yr. The temporary rise of anti-membrane antigen levels after local radiotherapy suggests that continued antigenic stimulation may be important for the maintenance of high anti-membrane antigen antibody levels.

- 1025 EPSTEIN-BARR VIRUS (EBV)-ASSOCIATED ANTIBODY PATTERNS IN MALIGNANT LYMPHOMA AND LEUKEMIA: I. HODGKIN'S DISEASE. (E.) Johansson, B. (Karolinska Hosp., Stockholm, Sweden), G. Klein, W. Henle and G. Henle. *Int J Cancer* 6(3):450-462, 1970.

Epstein-Barr virus (EBV) antibody titers were determined in the blood of patients with Hodgkin's disease. Sera from Swedish patients with Hodgkin's disease and from normal donors were used; EBV was prepared from tumor biopsies from patients with Burkitt lymphoma, and antibody titration in the Hodgkin's disease sera was carried out in indirect immunofluorescence tests. Serum antibodies capable of blocking the direct membrane immunofluorescence reaction between EBV-carrying cell lines and a fluorescein-conjugated serum from a Burkitt lymphoma patient (the F-Mutua conjugate) were tested. Sera from Hodgkin's disease patients had higher titers of EBV antibody and F-Mutua conjugate than normals. In 47% of Hodgkin's disease sera a high EBV antibody titer (greater than 160) was found, compared to 17% of normal sera with high titers. Patients over 40-yr-old of both sexes had higher

ers of EBV antibody than did younger patients. titers of EBV antibody were found in Hodgkin's disease patients with paraganuloma (15% of patients having titers in excess of 160), granuloma, and sarcoma (83% of Hodgkin's sarcoma patients having titers in excess of 160). These findings showed an inverse relationship between abundance of lymphoid cells and EBV-associated serological reactivity. A similar relationship was found for patients having varying degrees of clinical symptomatology associated with Hodgkin's disease, including constitutional symptoms, low or high peripheral lymphocyte counts and slow or rapid sedimentation rates.

POLYRIBOSOMES AND MESSENGER RNA OF AVIAN VIRUS-INDUCED LEUKEMIA CELLS. (Fr.)
 Ger, C. (Gustave Roussy Inst., Villejuif, France), J. Imbenotte, F. Lacour and J. Harel. *Ann Inst Pasteur* 119(3):384-396, 1970.

Sedimentation characteristics of polyribosomes isolated from AMV-infected brown leghorn chicken leukemic cells (virus-producing myeloblasts from peripheral blood) were compared to those from bone marrow myeloblasts of normal 5-day-old baby chickens. Amount of polyribosomes with a sedimentation coefficient above 250 S was much higher in leukemic cells than in normal cells. The pulse-labeled RNA (32 P) in normal cell polyribosomes exhibited a peak of radioactivity in the 5-10 S fraction (centrifugation in 0.14 M NaCl or 0.05 M NaCl), while RNA from leukemic cell polyribosomes showed a peak in the 18 S fraction. The labeled polyribosomal RNA from leukemic cells of the fraction with a sedimentation coefficient above 18 S constituted 58-62% of the total radioactivity of RNA; this fraction ranged between 12 and 32% in normal cells. The nucleotide composition of the RNA from all centrifugal fractions from both normal and leukemic cells revealed similar levels of uridine nucleotide (approximately 30%), and lower amounts of adenine nucleotide (approximately 20 mole %). The 18-26 S fraction of polyribosomes from leukemic cells exhibited a lower content of guanosine and cytidine than the corresponding fraction from normal cells. The relationship between the higher amounts of heavy messenger RNA found in polyribosomes from leukemic cells to malignancy is not certain.

THE N-TERMINAL AMINO ACID SEQUENCE OF TWO AVIAN LEUKOSIS GROUP SPECIFIC ANTIGENS.
 Niall, H. D. (Massachusetts Gen. Hosp., Boston), G. Bauer and D. W. Allen. *Proc Nat Acad Sci* 67(4):1181-1186, 1970.

Two major group-specific antigenic proteins from avian leukosis virus have been compared by amino acid analysis, tryptic peptide fingerprinting and N-terminal sequence determination. Amino acid composition of group-specific antigen showed high values of alanine, leucine and glutamic acid for gs-a, whereas gs-b showed high values of leucine, glycine and aspartic acid, resp., indicating that these are distinct proteins with unique amino acid sequences; there was some similarity between residues 14-20 of gs-a

and residues 11-19 of gs-b. Sequence microheterogeneity was detected at residue 6 of gs-b, with both threonine and glutamic acid present in approximately equivalent amounts. This glutamic acid-threonine substitution is present in both tobacco mosaic virus and bacteriophage coat proteins.

1028 ANTIGEN COMMON TO A HERPES TYPE VIRUS FROM CHICKENS WITH MAREK'S DISEASE AND EB VIRUS FROM BURKITT'S LYMPHOMA CELLS. (E.) Ono, K. (Res. Inst. Microbial Dis., Osaka U., Japan), S. Tanabe, M. Naito, T. Doi and S. Kato. *Biken J* 13(3):213-217, 1970.

Double-diffusion precipitation tests demonstrated that herpes type virus isolated from a chicken with Marek's disease and Epstein-Barr virus (EBV) isolated from Burkitt's lymphoma cells shared a common antigen. Antisera for use in the immunodiffusion tests were prepared from adult humans with EBV-positive sera. Similar antigen lines were formed between EBV-positive human sera and the EBV antigen, and between EBV-positive human sera and chick herpes virus antigen. No antigen line was formed by either chicken herpes virus or EBV with any sera from chickens raised in vinyl isolators or with sera against duck embryo fibroblasts.

1029 PROPAGATION OF HERPES TYPE VIRUS ISOLATED FROM CHICKENS WITH MAREK'S DISEASE IN JAPANESE QUAIL EMBRYO FIBROBLASTS. (E.) Onoda, T. (Res. Found. Microbial Dis. Osaka U., Japan), K. Ono, T. Konobe, M. Naito, Y. Mori and S. Kato. *Biken J* 13(3):219-228, 1970.

The virological properties of a herpes-type virus grown in Japanese quail embryo fibroblasts (QUEF) were investigated; the virus had been isolated in duck embryo fibroblasts from a chicken with Marek's disease. In QUEF cultures, the characteristic morphological changes brought about by the virus were foci consisting of round refractile cells and multinucleate giant cells. When herpes-type virus-infected QUEF cultures were inoculated with anti-quail red blood cell serum and quail red cells, mixed agglutination was observed and almost all cultured cells were affected. No mixed agglutination was observed when infected QUEF cultures were tested with anti-quail red cell serum and duck red cells, indicating that the herpes-type virus-infected QUEF culture consisted exclusively of quail cells at the passage level examined. No infectious virus could be found in the supernatants of infected cultures, and no virus could be extracted by sonic or temperature-disruption of cells, indicating that the virus in infective QUEF cells was not cell-free. The propagation of virus in cell cultures was inhibited by 5-iododeoxyuridine. DNA synthesis occurred only in the nuclei of infected cells, as revealed by autoradiography with 3 H-thymidine. Hematoxylin-eosin staining revealed herpes-type intranuclear inclusion bodies in infected cells, and herpes virus antigen was demonstrated by the direct fluorescent antibody method in both cytoplasm and nucleus. Although the virus produced

plaques on monolayers of either QUEF or duck embryo fibroblast cells, the number of plaques in the QUEF monolayer was approximately $2 \log_2$ less than the number of plaques in the duck monolayer. Infected QUEF was injected into the chorioallantoic membrane of embryonated hen's eggs, with the result that the inoculated cells produced pocks on the membranes within 7-8 days after inoculation.

- 1030 ISOLATION OF HERPES TYPE VIRUS FROM CHICKENS WITH MAREK'S DISEASE USING DUCK EMBRYO FIBROBLAST CULTURES. (E.) Kato, S. (Res. Inst. Microbial Dis., Osaka U., Japan), K. Ono, M. Naito, T. Doi, N. Iwa, Y. Mori and T. Onoda. *Biken J* 13(3):193-203, 1970.

The characteristics of a Herpes type virus isolated from chickens with Marek's disease were investigated. Chicken blood from birds with Marek's disease was cultured with duck embryo fibroblasts, and viral cytopathic agents were isolated from cultures. Cytopathic agents produced foci characterized by refractile rounded or shrunken spindle cells and syncytial type giant cells. In the infected duck embryo fibroblast cultures, these foci exhibited typical herpes type intranuclear inclusions and intracytoplasmic eosinophilic inclusions, as revealed by hematoxylin-eosin staining. Labeling studies with ^3H -thymidine showed that DNA synthesis continued in the nuclei of the cells in the infectious foci; cells in these foci showed specific fluorescence using the fluorescent antibody technique. Supernatants from infected cultures apparently contained no infectious agent, and ultrasonic disintegration abolished the infectivity of a virulent infected duck embryo fibroblast suspension. Electron microscopy revealed naked particles similar to those of herpes virus in infected foci, as well as occasional particles with an additional membrane. Morphologically, particles consisted of a hexagonal capsid and a central core, reminiscent of herpes virus particles. Inocula containing intact cells was required in order to induce the cytopathic effect by viral agents in cell cultures. The cytopathic agents could not be shown to have transforming activity. Although herpes type virus was recovered after inoculation into day-old chicks, duck embryo fibroblast-passaged herpes type virus apparently had no pathogenic efficacy for chickens.

- 1031 DEMONSTRATION OF A HERPES-TYPE VIRUS IN SHORT-TERM CULTURED BLOOD LYMPHOCYTES ASSOCIATED WITH MAREK'S DISEASE. (E.) Campbell, J. G. (Brit. Empire Cancer Campaign Res., Edinburgh, Scotland) and G. N. Woode. *J Med Microbiol* 3(3):463-473, 1970.

Lymphocytes were cultured from chickens with Marek's disease and examined by electron microscopy. Cultures exhibited a blast form in 72-96 hr, with transformation of about 4% of the cultured lymphocytes into blast cells. Transformed cells, which came from chickens with classical Marek's disease, were 2-4 times the size of unaltered lymphocytes and showed large, often misshapen, vesicular nuclei,

marginated chromatin, and occasional disruption of the nuclear membrane. Typical, hexagonal, herpes-type virus particles were present in many of the transformed cells. Most of the particles were immature and had a single envelope surrounding a nucleoid of variable density. Empty and double-enveloped particles were also seen, but the latter rarely. Some virus particles were associated with intranuclear filaments, which may have been the product of aberrant viral replication. Some untransformed cells also showed granule-lamellar arrays in the cytoplasm, possibly representing the inner structure of the filaments. When kidney cells from healthy chicks were incubated with lymphocytes cultured from birds with Marek's disease, a cytopathic effect was produced within 3 wk. The reaction was necrotic, with microplaques and long delicate cytoplasmic threads extending across the plaque. Similar results were obtained using fresh lymphocytes or tumor cells from cases of acute Marek's disease. Indirect immunofluorescence showed that a high proportion of transformed lymphocytes from cases of Marek's disease contained a viral antigen, as did the kidney cells in the region of the cytopathic effect. Transformed lymphocytes from cases of acute Marek's disease with gonadal tumors also included a herpes-type virus.

- 1032 PROTEIN SYNTHESIS IN NORMAL, X-IRRADIATED AND FRIEND VIRUS INFECTED MOUSE SPLEEN NUCLEI. (E.) Munson, B. R. (Roswell Park Mem. Inst. Springville, New York) and R. J. Fiel. *Res Commun Chem Path Pharmacol* 1(4):517-525, 1970.

The incorporation of amino acids in the nuclei of normal, X-irradiated, and virus-infected cells was investigated. Mice were exposed to whole-body irradiation (60 rads/min) or injected with 0.2 ml of a 10% spleen homogenate infected with Friend virus. At various times thereafter, mice were killed and amino acid incorporation in the nuclei of their spleen cells was assayed. When *in vitro* incorporation of amino acid into nuclei isolated from normal and Friend virus-infected mice were compared, it was seen that nuclei isolated from infected mice incorporated less amino acids than normal cells. Amino acid incorporation in nuclei from mice infected 4 days earlier was similar to that from normal mice. However, the rate of amino acid incorporation in nuclei from cells infected 25 days earlier was less than 50% that of normal cells. In nuclei isolated 4 days after X-irradiation amino acid incorporation was stimulated 6-fold over that of normal controls, while in nuclei isolated 18 days after X-irradiation the rate was stimulated 3-fold.

- 1033 ERYTHROCYTE OSMOTIC FRAGILITY IN FRIEND VIRUS-INFECTED MICE. (E.) Parr, I. B. (Chester Beatty Res. Inst., Sutton, Surrey, England) and K. E. K. Rowson. *Europ J Cancer* 6(5):411-415, 1970.

Osmotic fragility was investigated in the erythrocytes of mice infected with Friend leukemia virus (FLV). Erythrocyte osmotic fragility was deter-

ed by exposing erythrocytes from virus-infected mice to various concentrations of buffered saline pH 7.4; the ability of the spleens of normal and virus-infected mice to take up ^{14}C chromium-labeled erythrocytes was also studied. When normal and infected erythrocytes were incubated in saline for 30 min, infection with FLV could not be shown to affect erythrocyte fragility until late in the course of the disease, at which point there was still no change in the mean concentration of saline causing 50% erythrocyte lysis. However, in cells incubated for 30 min, there was an increase in the proportion of erythrocytes which were both more and less fragile than the average. When normal and virus-infected erythrocytes were incubated for 72 hr, erythrocytes from infected mice appeared to lyse more readily than normal erythrocytes; there was an increase in mean osmotic fragility of erythrocytes as early as 15 days after virus injection. Tonicity causing 50% lysis in normal and infected erythrocytes incubated in saline for 72 hr was 0.65 and 0.68 on day 15 after virus injection, and 0.74 on day 23 after virus injection. Splenectomized mice, survival after FLV injection was prolonged, and the onset of increased osmotic fragility and anemia were delayed but not prevented. Erythrocytes labeled with ^{14}C chromium were taken up by the spleen of FLV-infected mice about twice as rapidly as they were taken up by the spleen of normal mice (6.3% and 3.5%, resp.).

4 WILD-TYPE GROSS LEUKEMIA VIRUS AND THE PATHOGENESIS OF THE GLOMERULONEPHRITIS OF ZEALAND MICE. (E.) Mellors, R. C. (Hosp. Spec. Lab., New York, N.Y.), T. Shirai, T. Aoki, R. J. G. and K. Krawczynski. *J Exp Med* 133(1):113-119, 1971.

A hypothesis that spontaneous glomerulonephritis in NZB and (NZB x NZW) F_1 hybrid mice is associated with the formation by the mice of natural antibodies against antigens of Gross leukemia virus was tested. Kidney homogenates and kidney eluates from mice of these strains were assayed for the presence of Gross virus antigens and antibodies. Only mice having glomerulonephritis demonstrated by proteinuria were used. Soluble antigen was detected in the plasma and eluate of mice with proteinuria from 8-14 months of age. G natural antibody was found in none of the kidney homogenates, but in all of the kidney eluates. Tests for antinuclear antibody, anti-erythrocyte antibody and G natural antibody were performed on acid-eluate of kidneys of NZB mice, with the result that the normalized titer of G natural antibody in the kidney eluate was 25 and 12 in the serum. Titer of antinuclear antibody in kidney eluate was 25 and 32 in the serum. Anti-erythrocyte antibody titer in kidney eluate was 25 and 56 in the serum. (NZB x NZW) F_1 hybrid mice were positive for complement-fixing murine leukemia virus antigens. Hybrid mice developed glomerulonephritis and produced soluble antigens and free G natural antibodies earlier in life than did NZB mice. As G soluble antigen was progressively eliminated from hybrid mice, the proteinuria manifestation of glomerulonephritis became increasingly conspicuous. Gross

leukemia virus-specific antigens and bound immunoglobulins were found in glomerular lesions of hybrid mice, both in the mesangium and in the wall of the peripheral capillary loop of the glomeruli. Apparently, the pathogenesis of glomerulonephritis is related to the formation of antibodies against Gross virus antigens, and specifically to the deposition of immune complexes of G natural antibodies with G soluble antigen in the glomeruli.

1035 INCREASED INCIDENCE OF LYMPHOMA IN C3H/HeJ ADULT MICE INJECTED WITH GROSS VIRUS AND ANTITHYMOCYTIC SERUM. (E.) Vredevoe, D. L. (Sch. Nurs., U. California, Los Angeles) and E. F. Hays. *Infect Immun* 2(6):723-726, 1970.

The effect of antithymocyte serum (ATS) on the development of lymphomas in mice injected with Gross leukemia virus was investigated. Mice were given regimens of 1-4 weekly i.p. doses of cell-free filtrate of a Gross virus-induced lymphoma and 0.2 ml doses of ATS; controls were given cell-free filtrate and normal rat serum in place of ATS. The incidence of lymphoma was higher in each of the ATS-treated groups than in controls. Incidence of lymphoma increased as the number of cell-free filtrate doses increased; the maximum incidence was attained at 3 injections of cell-free filtrate, at which point 79% of rats in the ATS group showed lymphomas, compared to less than 50% of rats given normal rat serum. Rats given 3 and 4 doses of ATS had markedly shorter latent periods for the development of lymphomas than rats given normal rat serum; at 4 doses, latency for ATS-treated rats was 119-266 days, and latency for controls was 239-298 days.

1036 AN IMMUNOFLUORESCENT FOCUS ASSAY FOR GROSS LEUKEMIA VIRUS. (E.) Woods, W. A. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), J. Massicot and M. A. Chirigos. *Proc Soc Exp Biol Med* 135(3):772-777, 1970.

An immunofluorescent focus assay technique for Gross leukemia virus was developed which demonstrated Gross leukemia virus in tissues and fluids of AKR strain mice, and which permitted the assay of virus-neutralizing antibody in tissue cultures. Viruses in cell suspensions were frozen and thawed, and sera were diluted in 10% fetal calf serum and inactivated at 56° before testing. Equal volumes of serum and virus were mixed and incubated, and 0.1 ml of virus-serum mixture was inoculated onto three-ring cultures on slides; slides were then incubated. Anti-Gross leukemia virus serum was prepared in rats, and immunofluorescent staining was carried out according to standard procedures. Diffuse foci of strongly fluorescent cells were observed in cultures infected with Gross virus after staining with rat-anti-Gross leukemia virus serum or rat anti-murine sarcoma virus serum. Blocking experiments showed that staining of cultures infected with viruses other than Gross virus with anti-Gross virus serum produced fluorescent staining of almost all cells, and that staining was due to the group-spe-

cific antigen. Inoculation of Gross virus onto cultures of mouse cells from various sources produced titrations of between 2×10^1 and 4×10^5 focus forming U/ml culture 7-35 days after inoculation.

- 1037 RNA-DEPENDENT DNA POLYMERASE ACTIVITY IN FIVE RNA VIRUSES: DIVALENT CATION REQUIREMENTS. (E.) Scolnick, E. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), E. Rands, S. A. Aaronson and G. J. Todaro. *Proc Nat Acad Sci* 67(4): 1789-1796, 1970.

This study compares the effects of manganese and magnesium on DNA synthesis by RNA-dependent DNA polymerase in Rauscher leukemia virus. Synthesis of DNA from viral RNA of intact virions occurred equally well with either magnesium acetate or manganese acetate. However, at limiting concentrations of divalent cation (1×10^{-3} M) manganese was more effective; with synthetic RNA polymer used as template, a 50- to 100-fold stimulation of activity occurred in the presence of manganese with optimal concentrations for synthesis from endogenous viral RNA being too high for optimal synthesis with the synthetic template. At either 4×10^{-3} M magnesium or 4×10^{-3} M manganese, DNA synthesis from endogenous viral RNA is optimal. Conditions that are optimal for detecting polymer-stimulated activity in murine leukemia virion are effective for murine mammary tumor virus and avian myeloblastosis virion. Two nononcogenic viruses, visna virus and primate syncytium-forming virus, exhibit similar DNA polymerase activity.

- 1038 RAUSCHER VIRUS AND ITS EFFECT ON RNA SYNTHESIS IN SPLEEN CELLS OF BALB/c MICE. (Rus.) Kiselev, F. L. (Acad. Med. Sci. USSR, Moscow), G. G. Shatalova, L. A. Semenova, N. A. Varich and I. S. Irlin. *Vop Virus* 15(5):589-596, 1970.

The presence of a specific RNA_x fraction in mouse spleen cells during the early stages of Rauscher virus-induced leukemogenesis was ascertained. Experimental BALB/c mice were inoculated i.v. with Rauscher virus at a 1:1000 dilution which led to the development of more than 50 colonies in the spleen. Spleen cells were isolated at various stages of leukemogenesis and RNA was extracted after double phenolic deproteinization. No differences in sucrose gradient sedimentation characteristics were noticed between RNA preparation from normal and infected cells. Further fractionation on cellulose columns for the segregation of double- and single-stranded RNA showed within the single-stranded fraction the presence of an additional fraction called RNA_x, with a buoyant density of 1.6 in a cesium sulfate gradient. This density was lower than that of the usual single-stranded RNA and was typical for the intermediate replicative forms in animal viruses; it was also indicative of a more ordered configuration with respect to the usual single-stranded RNA. Sucrose gradient centrifugation situated RNA_x at the level of the 28 S

ribosomal RNA with a shoulder having a lower sedimentation constant, indicating its heterogeneity and precluding the determination of its molecular weight from the sedimentation characteristics. RNA_x was found in both normal and infected spleen cells; substantially higher amounts were found in the latter. Studies of the effect of viral infection on the accumulation of RNA_x in various stages of leukemogenesis showed RNA_x reaching a peak (12-14% of the total single-stranded RNA) on the 3rd day following inoculation and decreasing thereafter. Levels of RNA_x accumulation were dependent on the amount of Rauscher virus inoculation. This phenomenon was noticed only in Rauscher virus replication susceptible systems such as BALB/c mouse spleens and did not occur in C57BL/6 mouse spleens which are resistant to Rauscher virus infection.

- 1039 ELECTRON MICROSCOPIC STUDY OF THE GUINEA PIG LEUKEMIA VIRUS. (E.) Feldman, D. G. (VA Hosp., Bronx, N.Y.) and L. Gross. *Cancer Res* 30(11):2702-2711, 1970.

The structure of virus particles and their distribution, formation and location in relation to cell components in the guinea pig are described and compared to particles found in mouse leukemia. Strain 2 and F₁ hybrid guinea pigs were inoculated subcutaneously with 10 or 20% leukemic cell suspension and leukemic plasma. All inoculated animals developed stem cell leukemia and were sacrificed when the disease was fully developed 14 to 46 days after inoculation at which time peripheral blood counts exceeded 250,000 to 3,000 WBC/mm³. Fragments of various organs of leukemic animals and non-inoculated control animals were removed and processed for electron microscopic studies and for routine light microscopy. All leukemic animals revealed leukemic virus particles in the tissue examined. Immature virus particles with electron-lucent centers and two concentric shells were observed budding from the membranes or free within the cisternae of the endoplasmic reticulum. Mature virus particles with electron-dense nucleoids and single, thick outer shells were found mainly in the intercellular spaces. Structurally these differed from mouse leukemia virus which presents a relatively thin and smooth unit membrane of the outer coat and a nucleoid which varies from opaque to electron-lucent and often exhibits pleomorphism. A process of reverse pinocytosis may possibly describe the movement of particles from the interior to the periphery of the cell.

- 1040 VIRUS-INDUCED MYELOGENOUS LEUKAEMIAS OF THE MOUSE: ELECTRON MICROSCOPIC AND MORPHOMETRIC STUDIES. (Ger.) Fritsch, R. S. (German Acad. Sci., Berlin, Germany). *Veroeff Morph Path* 48:1-128, 1971.

Electron microscopy and morphometry applied to the study of the morphology and leukemogenesis of Graffius virus-induced myelogenous leukemias in AB/Jena mice revealed the number of cytoplasmic myeloid granules per area unit (Zgr) as the most appropriate ultra-

structural parameter for the characterization of the stages of myelogenous cell maturation. Myelogenous leukemias were thus classified into undifferentiated (myeloblastic and paramyeloblastic leukemias), moderately differentiated (of which 90% are chloroleukemias), well-differentiated myelogenous leukemias (in which 76% of cell infiltrates appear yellowish); the defining characteristics in the 2 latter cases were associated with their verdoperoxidase contents. All leukemias presented intercellular C-type virus particles and intramegakaryocytic A₃-type virus particles. Crystalline inclusions (20-25 Å diameter) were observed within phagocytes and kidney tubular cells in some of the well-differentiated leukemias; these inclusions were considered to be protein containing deposition products of hemoglobin resulting from erythrocytic degeneration. The first passage of cell-mouse reticuloendothelial ascites sarcoma filter (RAB-1), inoculated into 136 mice, induced exclusively myelogenous leukemia in 50% of the animals. Serial filtrate passages (5 or 6) led to an increase in virulence and induced diversification into several genetic types of induced leukocytoses in 89-95% of infected animals. Morphometrical ultrastructural analysis allowed detection of quantitative differences between normal granulocytopenia and the corresponding preleukemic process; an ultrastructural morphological myelogram was established using the frequency distribution of the relative number of cytoplasmic vacuoles (Zgr).

THE EFFECT OF ACID DEOXYRIBONUCLEASE ON THE LEUKOCYTES AND BONE MARROW CELLS OF PS-MICE INDUCED LYMPHOBLASTIC LEUKEMIA IN PS-MICE.

(Rus.) Eschenbach, C. (Child. Clin. U. Marburg, Germany), G. Ludwig, W. Kühnel and C. Förster. *Immunologie* 2(3):387-402, 1970.

The effect of deoxyribonuclease (DNase II) on the leukocytes of peripheral blood and on bone marrow cells of PS mice with virus-induced lymphoblastic leukemia is described. The mice were inoculated at the age of 3 wk with an organ extract of leukemic infiltrated lymph nodes and spleen containing lymphoblastic leukemia cells from a leukemic mouse of the same strain. A large percentage of the inoculated mice revealed lymphoblastic leukemic cells in their peripheral blood 3 or 4 wk after the inoculation with a count of 50,000/mm³ within a few days. The DNase II activity of 100 Kunitz units was injected at various intervals. The results showed that the DNase II had a cytotoxic effect on the lymphoblastic leukemia cells, and these cells were affected more severely than the neutrophilic granulocytes and lymphocytes of the healthy mice. In the healthy mice, as well as in the animals in the preleukemic stage of the disease, the DNase II (16 x 0.4 mg/kg), induced a decrease in the leukocyte count 48 hr after administration in the peripheral blood of 60% of the initial value; the leukemic mice reacted with a decrease of 90 to 95%. The marked cytotoxic effect of the enzyme on the leukemic cells is evident from the temporary shrinkage of the infiltrate quantity at the site of inoculation where necrosis of single cells is seen; during this period an increase in granulopoiesis and myelopoiesis was observed in the

bone marrow. Deoxyribonuclease appears to have a greater cytotoxic effect on lymphoblastic leukemia cells than on normal leukocytes.

- 1042 IMMUNOSUPPRESSIVE EFFECTS OF DNA VIRUSES: PAPOVA VIRUS AND HUMAN ADENOVIRUS TYPE 16. (Rus.) Gamburg, V. P. (Acad. Med. Sci., USSR, Moscow), O. E. Shcherbakova and G. Ya. Svet-Moldasky. *Vop Virus* 15(5):612-614, 1970.

Immunosuppression response to inoculation of live Sendai virus into animals previously inoculated with SV40 and adeno type 16 viruses was studied in Syrian male hamsters 2 months of age. Antibodies to Sendai virus were determined at various intervals following immunization. The average antihemagglutinin titers expressed logarithmically were much lower in the SV40 or adeno type 16 virus inoculated hamsters than in the control animals which were immunized with Sendai virus only 15 and 23 days following specific immunization. Another experiment was performed with hamsters treated as follows: 1) immunized with Sendai virus following inoculation with SV40 virus, 9 days earlier; 2) immunized with Sendai virus following previous inoculation with uncontaminated green monkey kidney culture media; 3) immunized with Sendai virus only; 4) simultaneously immunized i.p. with SV40 and Sendai virus. The levels of specific antihemagglutinins in sera of group 1 hamsters were much lower than in those inoculated with Sendai virus only (group 3). Simultaneous inoculation with SV40 and Sendai virus (group 4) or inoculation with culture media of green monkey kidney (group 2) had no effect on the specific antibody levels of the sera. The immunosuppressive effect manifested by these viruses appears to support a carcinogenic mechanism in which immunosuppression constitutes one of the conditions for the occurrence of malignancy.

- 1043 STRUCTURAL PROTEINS OF ADENOVIRUSES. (E.) Petterson, U. (Wallenberg Lab., U. Uppsala, Sweden). *Acta Univ Uppsala* 89:1-21, 1970.

Adenovirus capsid proteins were obtained in purified form and characterized. Adenovirus hexon antigens were purified from infected KB cells and characterized by analytical ultracentrifugation, immunodiffusion, and electron microscopy. The hexons had the form of prolate ellipsoids, probably with cylindrical shapes measuring 76 x 119 Å, and a molecular wt of 400,000. The hexons were found to be free of carbohydrates, contained 0.5-0.8% half-cystine, and had a general amino acid composition similar to that of the whole virion, except that the virion had a higher arginine content than the hexon; no free N-groups were found on the hexon polypeptide chain. Antisera prepared with the purified hexon did not contain significant amounts of neutralizing antibodies, in contrast to antisera prepared with hexons which were partially purified. Fiber antigen from adenovirus was purified as was hexon antigen. The form of the fiber antigen was that of an extended structure with a knob at the end, and the molecular wt of the single type of

polypeptide detected was 70,000. High titers of neutralizing antibodies were observed for antisera against purified fiber antigens when neutralization was measured with focus-forming unit assay, while the plaque assay gave only insignificant titers. Purified penton antigens appeared as complex units each with a 90 Å base and a 200 Å projection, and some units had pentagonal outlines; the molecular wt of the penton was 400,000. The bonds between fiber and penton base were not covalent; fibers could be dissociated from bases by an 8% pyridine soln. Intact pentons and their free bases caused a cytopathic effect when added to monolayer cultures of KB cells.

- 1044 CELLULAR DNA SYNTHESIS IN PRODUCTIVE INFECTION WITH ADENOVIRUSES. (E.) Takahashi, M. (Res. Inst. Microbial Dis., Osaka U., Japan), K. Baba and Y. Minekawa. *Int J Cancer* 6(3):399-409, 1970.

The effect of adenoviruses on cellular DNA synthesis (^3H -thymidine incorporation and DNA-DNA hybridization studies) in productive infection of hamster kidney cells (HamK) and human embryonic lung cells (HEL) was investigated. After 24 hr adenovirus type 5 (Ad5)-infected HamK cells that had been treated with 5-fluorouracil (FU, 13 $\mu\text{g}/\text{ml}$) and thymidine (0.5 $\mu\text{g}/\text{ml}$) showed lower ^3H -thymidine incorporation than untreated cells (2.8 and 9 cpm/ μg DNA $\times 10^4$, resp.), but remained higher than uninfected cells treated with FU or untreated (1.3 and 0 cpm/ μg DNA $\times 10^4$, resp.). The newly synthesized ^3H -DNA was mainly cellular DNA between 16 and 32 hr after infection in FU-treated cultures, and synthesis of viral DNA was delayed and reduced in FU-treated cells (560 cpm after 28-32 hr compared to 3,343 cpm in untreated cells). When long-term labeling of DNA was studied in the presence of hypoxanthine, aminopterin, and glycine (to prevent endogenous biosynthesis of thymidylic acid), incorporation of counts into cellular DNA was 3 times higher in Ad5-infected cells (12,488 cpm) than in uninfected cells (4,337 cpm) suggesting that cellular DNA synthesis was stimulated by infection. Incorporation of ^3H -thymidine into cellular DNA in monolayer cultures of HEL infected with adenovirus types 2, 3, 4, 5, and 12 was 2-6 times higher than uninfected cultures 16-40 hr after infection, and the stimulation was detectable for prolonged periods (88-112 hr after infection), suggesting that the induction of cellular DNA synthesis by the infection had occurred.

- 1045 PRODUCTION OF HIGH TITRES OF INTERFERON IN CHICKEN LEUKOCYTES INOCULATED WITH HUMAN ADENOVIRUS TYPE 12. (E.) Mucsi, I. (U. Med. Sch. Szeged, Hungary), R. Pusztail, I. Beladi and M. Bakay. *Acta Virol* 14(6):453-458, 1970.

The effect of infection with human adenovirus type 12 on interferon production in chicken leukocytes was investigated. Chicken leukocyte cultures were prepared and inoculated with $2 \times 10^{4.5}$ TCD₅₀ of adenovirus type 12. Adenovirus induced maximal

interferon titers when the concentrations of leukocytes were high; at concentrations of $12-14 \times 10^6$ cells/ml culture fluid, interferon titers were 5-8 (\log_2 values.) At lower concentrations of cells, interferon production was proportionally lower (interferon titers of 1 and 2 (\log_2) at concentrations of 8 and 10×10^6 leukocytes, resp.). Chicken leukocytes retained their interferon-producing ability after incubation at 36° for 48 hr (titers of 1024). When leukocytes were cultured with calf serum and then inoculated with virus, it was found that a serum content of 2.5% or more was required to produce higher titers of interferon (titer of 512 at 2.5% serum concentration); titers of interferon increased when serum concentrations were increased to 20% (interferon titer of 2049 at 20% concentration). Treatment of leukocytes with chloroquine (30 $\mu\text{g}/\text{ml}$) reduced interferon, and treatment with 40 μg chloroquine completely inhibited interferon production in cells inoculated with adenovirus. When viruses were treated with trypsin and then inoculated in leukocyte cultures, interferon production continued, but at reduced levels of efficiency. Leukocytes infected with human adenovirus type 12 apparently release a synthesized and not a preformed interferon.

- 1046 INHIBITION OF ADENOVIRUS REPLICATION BY CANAVANINE. (E.) Neurath, A. R. (Wyeth Lab., Philadelphia, Pa.), F. P. Wiener, B. A. Rubin and R. W. Hartzell. *Biochem Biophys Res Commun* 41(6):1509-1517, 1970.

The effect of canavanine on adenovirus replication *in vitro* was investigated. Adenovirus was cultured in human embryonic kidney cells to which arginine had been added in concentrations of 0.01 mM. Canavanine labeled with ^{14}C was added to cultures in amounts of 1 $\mu\text{mole}/\text{ml}$ culture, and the incorporation of ^3H -thymidine into DNA, the synthesis of viral capsid components and virions, and the synthesis of virus-specific tumor antigens were determined. Addition of canavanine decreased but did not prevent the incorporation of ^3H -thymidine into DNA of adenovirus-infected cells. Rate zonal centrifugation showed that the proportion of label incorporated into viral DNA was 6 and 13% of control when canavanine was added 14 and 24 hr, resp., after virus infection of culture. Apparently, canavanine prevented the initiation of viral DNA synthesis but did not prevent the transient increase of cellular DNA synthesis in infected cells. Canavanine also inhibited the formation of viral capsid components, including pentons, dodecons, and hexons. However, addition of canavanine to cells at the time of infection or later did not prevent the synthesis of adenovirus tumor antigens. Inhibition of adenovirus replication by canavanine was reversible; when canavanine was added at the time of virus infection and withdrawn 2-24 hr later, virus was synthesized but the eclipse period was prolonged by the amount of time canavanine was present. Canavanine added to cultures after the onset of DNA replication partially inhibited DNA synthesis and synthesis of capsid components, and completely blocked the assembly of both into virions.

7 THE RESPONSE OF BHK21 CELLS TO INFECTION WITH TYPE 12 ADENOVIRUS: IV. ACTIVATION DNA-SYNTHESIZING APPARATUS. (E.) Zimmerman, J. Jr. (Rutgers Med. Sch., New Brunswick, N.J.), Raska, Jr. and W. A. Strohl. *Virology* 42(4): 7-1150, 1970.

effect of infection with adenovirus type 12 on synthesis and on various enzyme systems was investigated in hamster cells. Hamster cells were infected with adenovirus type 12 to the point at 89% of cells stained positive for tumor antigen in immunofluorescent staining tests. DNA synthesis began to increase sharply at 12 hr after infection, rising from 1.80 cpm ^3H -thymidine incorporated $\times 10^{-3}/10^6$ cells at 12 hr to 13 cpm $\times 10^{-3}/$ cells at 21 hr; thereafter, DNA synthesis declined quickly, approaching the values for DNA synthesis in uninfected cells at 51 hr postinfection. Thymidine kinase activity reached its maximum level at 16 hr postinfection (10 nmoles of midylate/mg protein/10min). Increases of 136% and 72% were recorded for deoxycytidylate deaminase activity and for cytidine-5'-diphosphate reductase activity, resp., in virus-infected cells. DNA polymerase activity was increased in infected cells compared with controls; at 45 min postinfection, ^3H -TPP incorporation for infected and control cells, resp., were 2900 and 1500 cpm/mg protein.

8 GLYCOLYSIS IN ADENOVIRUS-INFECTED RAT CELL CULTURES AND IN ADENOVIRUS TYPE 12-INDUCED HAMSTER SARCOMA CELLS. (Rus.) Ageyenko, A. I. (P. A. Herzen Sci. Res. Inst. Oncol., Moscow, USSR), N. M. Imukhamedova, V. T. Timofeyev, I. Ya. Kogan and N. Saprin. *Vop Onkol* 16(9):49-53, 1970.

Glycolysis was studied in rat embryo fibroblast (REF) monolayer cultures following inoculation with human adenovirus type 12, with the weakly oncogenic adenovirus type 3 and with the nononcogenic infectious adenovirus type 6; similar studies were done with *in vitro* cultivated adenovirus type-12 induced hamster sarcoma cells. Glucose utilization and lactic acid formation were the parameters followed. Control cultures were obtained with noninfected REF cultures, REF cultures inoculated with inactivated (56°C for 30 min) viruses or with virus-free inoculum medium. Intensified glycolysis was noticed in all cell cultures 2-4 hr following inoculation; it appeared most intense in adenovirus type 12-inoculated REF cultures. Glucose which was utilized in both inoculated and control cultures was completely converted into lactic acid under anaerobic conditions. Aerobic glycolysis occurring in both normal and virus-inoculated cultures was 3 times higher in adenovirus type 12-infected REF cultures and in adenovirus type 12-induced hamster sarcoma cell cultures compared to control cultures. Nearly complete conversion of glucose to lactic acid occurred under aerobic conditions in the case of the adenovirus type 12-inoculated cells while other glucose oxidation pathways seemed to be followed partially in the adenovirus types 3-6-inoculated REF cultures. The ratios between lactate and glucose under aerobic conditions 72 hr following inoculation were 0.7 in the control, 1.96

in the adenovirus type 12, 1.1 in the adenovirus type 3, 1.0 in the adenovirus type 6-inoculated REF cultures and 1.48 in the adenovirus type 12-induced hamster sarcoma cell cultures. The glycolytic shifts in both adenovirus type 12-inoculated REF culture and in the sarcoma cell cultures seemed to be similar. The amount of monolayer cells decreased slowly in the adenovirus type 6-infected culture while no such variations occurred in the adenovirus type 3 and 12 inoculated REF cultures.

1049 PROPERTIES OF THE TRANSFER RIBONUCLEIC ACID METHYLASE ACTIVITY *IN VITRO* OF HAMSTER TUMORS INDUCED BY ADENOVIRUS-12: BASE ANALYSIS. (E.) McFarlane, E. S. (Dept. Microbiol., Dalhousie U., Halifax, Nova Scotia, Canada) and C. G. Lee. *Biochem J* 120(3):499-503, 1970.

The *in vitro* tRNA methylase activity (the bases which are methylated, and the effects of ammonium acetate and pH) of adenovirus-12-induced hamster tumor, normal hamster liver, and normal hamster muscle-connective tissue was studied. Enzyme extracts from the virus-induced tumor and the normal tissues were active on both *Escherichia coli* tRNA and yeast tRNA substrates although the degree of methylation was greater with *E. coli* tRNA. The total activity recovered was higher with the virus-induced tumor extracts (in which 1-methyladenine, 3-methyladenine, and N^6 -methyladenine bases were produced) than in extracts from muscle-connective tissue (3-methyladenine and an unidentified pyrimidine base) or from liver (1- and 3-methyladenine). Muscle-connective tissue extracts yielded both the 3-methyladenine and the unidentified base from *E. coli* tRNA at a pH of 7.0 but only the 3-methyladenine at a pH of 8.5; the same extracts yielded both 3-methyladenine and the unidentified bases from yeast tRNA at a pH of 7.0 and only the 3-methyladenine at a pH of 8.5. Ammonium acetate (480 $\mu\text{mole}/2\text{ ml}$) did not affect the bases methylated but increased the total activity recovered.

1050 THE EFFECT OF IMMUNIZATION ON THE RATE OF GROWTH OF ADENOVIRUS TYPE 12-INDUCED SARCOMA IN HAMSTERS. (Rus.) Ageyenko, A. I. (P. A. Herzen Res. Inst. Oncol., Moscow, USSR), V. T. Timofeyev, I. S. Bashkayev and E. Sh. Vardosanidze. *Vop Onkol* 16(10):64-66, 1970.

The effect of immunization on the growth of human adenovirus type 12-induced sarcoma in hamsters was studied. Antigens were obtained by subjecting sarcomatous tissue homogenates to 1) freeze-thawing, 2) ultrasonic treatment with or without addition of Freund's adjuvant or 3) heating at 56°C , and inoculating 5-7 hamsters 4 times at weekly intervals. Additional groups were treated with fresh homogenate or supernate, with normal hamster tissue homogenates (liver, spleen, muscle) or with Freund's adjuvant alone. Tumor producing amounts of trypsin-treated transplantable sarcomatous cells (9.5×10^6 or 19×10^6) were inoculated 10 days after the last immunization into 4 axillary sites and animals were sacrificed 2 wk later. Transplantability was 100%

in all the experimental animals. Immunization with both intact and treated homogenates, normal tissues and Freund's adjuvant stimulated tumor growth. The stimulation coefficients expressed in relative weights of total tumor tissue as compared to those developed in control (nonimmunized) hamsters were 3.5-4.7 in case of homogenates subjected to freeze-thawing, 5.3 in case of ultrasound treatment with addition of Freund's adjuvant, 3.8 when the homogenate was exposed to ultrasound only, 4.8 in case of normal tissue homogenates and 3.6 in the case of inoculation Freund's adjuvant only, when hamsters were injected with 19×10^6 tumor cells. No such effects were noticed in hamsters inoculated with homogenates heated at 56°C and then injected with 9.5×10^6 tumor cells. Massive inoculation with tumor tissue (19×10^6) seemed to produce immunosuppressive effects. The role of stimulation of tumor growth by immunization is still an open question in carcinogenesis.

- 1051 INTEGRATION OF THE DEOXYRIBONUCLEIC ACID OF ADENOVIRUS TYPE 12 INTO THE DEOXYRIBONUCLEIC ACID OF BABY HAMSTER KIDNEY CELLS. (E.) Doerfler, W. (Rockefeller U., New York, N. Y.). *J Virol* 6(5):652-666, 1970.

This study demonstrates the integration of viral DNA of adenovirus type 12 (Ad12) into cellular DNA of baby hamster kidney cells through covalent linkage. Adsorption of ^3H -Ad12 to baby hamster kidney cells occurred more efficiently at low concentrations with release of 82% of the ^3H activity that was cell associated being recovered in the medium at the end of 2 hr. The parental viral label hybridized predominantly to viral DNA and later to cellular DNA with a 25 to 1,380-fold higher value in infected cells as compared to uninfected control cells. Integration values are calculated to be 5-55 Ad12 DNA equivalents per cell, with only slightly lower values in the presence of cytosine arabinoside, cycloheximide and actinomycin D, indicating that DNA replication is not necessary for integration to occur.

- 1052 ADENOVIRUS TYPE 2-SIMIAN VIRUS 40 HYBRID POPULATION: EVIDENCE FOR A HYBRID DEOXYRIBONUCLEIC ACID MOLECULE AND THE ABSENCE OF ADENOVIRUS-ENCAPSIDATED CIRCULAR SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID. (E.) Crumpacker, C. S. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), M. J. Levin, W. H. Wiese, A. M. Lewis, Jr. and W. P. Rowe. *J Virol* 6(6):788-794, 1970.

Adenovirus type 2 (Ad2) and simian virus 40 (SV40) DNA components of the hybrid population plaque variant high efficiency yielder (Ad2⁺HEY) were studied by equilibrium density centrifugation, and nucleic acid hybridization (with the virus-specific complementary RNA synthesized *in vitro*) and supercoiled SV40 DNA (form I) were investigated with alkaline sucrose gradients. The Ad2⁺HEY population contained a recombinant genome composed of Ad2 and SV40 DNA linked together within the same molecule; the failure of alkaline denaturation to

separate the components indicated a covalent linkage. Alkaline sucrose gradients of a mixture of ^{32}P -labeled SV40 DNA and ^3H -labeled Ad2 DNA revealed the broad peak expected for the denatured linear duplex molecule (Ad2 DNA) and 2 peaks for the SV40 DNA (the form I component and a mixture of forms II and III), while a mixture of ^{32}P -labeled Ad2⁺HEY DNA and ^3H -labeled Ad2 DNA revealed no SV40 DNA form I component. The DNA from the Ad2⁺HEY population apparently consists of nonhybrid Ad2 DNA and an Ad2-SV40 hybrid DNA.

- 1053 ENHANCEMENT OF ADENOVIRUS PLAQUE FORMATION ON HeLa CELLS BY MAGNESIUM CHLORIDE. (E.) Williams, J. F. (Inst. Virol., Glasgow, Scotland). *J Gen Virol* 9(3):251-255, 1970.

The effect of magnesium chloride on plaque-formation by adenoviruses in infected cultures of HeLa cells was investigated. Magnesium chloride in amounts ranging from 12-50 mM were added to cultures, with the result that adenovirus plaques began to appear in cultures 2-3 days earlier than normally; maximum plaque counts were also attained 2-3 days earlier than normally. In cultures supplemented with 25 mg magnesium chloride, 7 plaques were counted/50 mm petri dish on day 4, with maximal counts (50 plaques) falling on days 10-12. Optimal amounts of magnesium chloride for plaque-formation enhancement were between 25-30 mM; numbers of plaques began to decline when magnesium chloride supplements exceeded 30 mM. To determine whether the increased plaque-formation brought about by magnesium chloride was due to increase in viral yield at high magnesium chloride concentrations, infectivities were measured for intracellular and extracellular virus in cells infected with adenovirus at input multiplicities ranging from 0.05-5 plaque-forming units/cell. At low multiplicities of infection, levels of extracellular virus were 10-30-fold higher in cultures containing 25 mM of magnesium chloride, while levels of intracellular virus were not affected. Apparently, the effect of magnesium chloride supplement on plaque formation is due to an increase in the rate of virus release from infected cells.

- 1054 IMMUNOLOGICAL BASIS OF THE ADENOVIRUS 8-9 CROSS-REACTION. (E.) Hierholzer, J. C. (Ctr. Dis. Control, Atlanta, Ga.) and W. R. Dowdle. *J Virol* 6(6):782-787, 1970.

Cross-reactivity between the dodecon component purified 304- to 362-fold (fluorocarbon extraction, calcium phosphate batch chromatography, and ion exchange chromatography) and the hexon component purified 230- to 240-fold (erythrocyte adsorption, ion exchange chromatography, and exclusion chromatography) of adenovirus types 8 and 9 was studied. A bilateral but predominantly one-sided cross relationship existed between dodecons of types 8 and 9 in hemagglutinin inhibition tests with type 9 reacting equally well against type 8 (2560 titres) or type 9 (2560) antigens while type 8 reacted significantly less with type 9 antigen (40) than with the homologous antigen (2560). Dodecons and hexons

both types exhibited some neutralizing activity (0-80), and combining anti-dodecon and anti-hexon sera or producing antisera against a mixture of dodecon and hexon components produced neutralizing sera identical to those against crude virus. Dodecons and hexons of each type apparently shared at least 1 antigenic determinant (on the vertex hexamer). Complement fixation, neutralization, and immunodiffusion demonstrated group- and type-specific determinants in the hexon components.

5 TRANSPLANTATION IMMUNITY FOLLOWING IMMUNIZATION WITH EXTRACTS OF ADENOVIRUS 12

TUMOR CELLS. (E.) Potter, C. W. (Lodge Moor Hosp., Sheffield, England) and J. S. Oxford. *Int J Cancer* 5:410-414, 1970.

Induction of transplantation immunity by immunization with cells from tumors induced in mice with adenovirus 12 was investigated. Tumor extracts were prepared from transplanted adenovirus 12-induced tumors of mice and hamsters by freezing and thawing and centrifugation at 100,000 x g for 1 hr; the extracts were filtered through Millipore filters. CBA strain mice immunized by a s.c. injection of 0.1 ml of the adenovirus-induced tumor extract were challenged with 5×10^5 viable tumor cells 1, 2, or 3 wk later. No immunity was conferred by tumor cells in mice challenged 1 wk after immunization (95-100% of mice developing tumors); however, a significant reduction in tumors was seen in mice challenged 2 and 3 wk after immunization, immunized in these categories developing tumors in 70-100% of cases. Mice immunized with 3 doses of filtered tumor cell extract and challenged with viable tumor cells developed tumors in 3/20 cases, while mice immunized with antigen extracts from normal CBA tissue developed tumors upon challenge in all cases. Mice immunized with antigen extracts from transplanted hamster tumors induced by SV40, chick embryo lethal orphan virus, and adenovirus showed no immunity to tumor development on challenge with tumor cells. Apparently, a soluble extract of adenovirus 12 tumor transplantation antigen is present in tumors induced in CBA mice by adenovirus 12.

6 STUDIES OF THE ENHANCEMENT OF AN ADENOVIRUS ASSOCIATED VIRUS BY HERPES SIMPLEX VIRUS.

(E.) Blacklow, N. R. (Natl. Inst. Allergy Infect. Dis., 1. Inst. Hlth., Bethesda, Md.), R. Dolin and M. D. Hagan. *J Gen Virol* 10(1):29-36, 1970.

The interaction between herpes simplex virus type I and adenovirus-associated virus type I (AAV) was investigated; quantitative kinetic procedures were employed to examine herpes virus replication and the activity of AAV and herpes virus-infected cells to produce AAV antigen detectable by immunofluorescent tests. Cultures of Hep-2 cells inoculated with AAV alone failed to produce immunofluorescent antigen, but when co-infected with AAV and herpes simplex virus, the cells showed AAV specific antigen. Between 6-18 days after infection, titers of herpes simplex virus were from $2.5-6.5 \log_{10}$ TCID₅₀/ml. AAV fluorescent

cells increased from 0.03% to 5.0% 6-12 hr after infection. Dose response studies showed that a single infectious AAV particle and a single infectious herpes simplex virus particle were sufficient to initiate AAV antigen synthesis. In co-infected cultures, AAV antigen was produced before herpes simplex virus. When arginine was removed from co-infected cultures, it was found that herpes simplex virus was not produced, while AAV antigen production proceeded as in arginine-positive cultures, but at a slower rate, the percentage of AAV fluorescent cells at 12 hr postinfection being 0.05%. Preinfection with herpes simplex virus lengthened the 6 hr latent period for AAV antigen production. When co-infected cultures were treated with cytosine arabinoside AAV antigen production was abolished.

1057 PATHOGENICITY STUDIES IN RABBITS, HAMSTERS, MICE AND EMBRYONATED EGGS WITH HERPES T VIRUS VARIANTS. (E.) Daniel, M. D. (Harvard Med. Sch., Southboro, Mass.) and L. V. Melendez. *Arch Gwa Virusforsch* 32(1):45-52, 1970.

The pathogenicity and antigenicity of a large plaque variant (LPV) and a small plaque variant (SPV) of herpes tumor virus was investigated in mice, hamsters, rabbits and embryonated chicken eggs. Both variants formed pocks when inoculated in embryonated eggs; LPV formed larger pocks than SPV, and the LPV-induced pocks appeared 2 days after inoculation, while SPV-induced pocks appeared after day 3. LPV intracerebral inoculation was 100% fatal in weaned and adult mice, death ensuing in 3-7 days. Seventy percent mortality was observed in weaned mice inoculated i.m. with LPV; mortality declined to 16% in mice inoculated at 7 wk-of-age. SPV proved fatal only to 1-day-old mice; intracerebral inoculation of weaned and adult mice was not fatal. Mice inoculated with SPV showed a 90% survival when challenged with LPV inoculations 21 days later. LPV was 100% lethal in 4-day-old hamsters and 93% lethal in weaned animals with intracerebral inoculation; it was not lethal when inoculated by s.c., i.m., or i.p. routes. SPV was lethal to 1 and 2-day-old hamsters by the intracerebral route but with inoculation at 4 days, survival rose to 56% and to 100% at 3 wk. Corneal scarification and instillation of 2 drops of LPV in rabbits produced acute conjunctivitis and keratitis by 3 days postinfection. SPV administered similarly failed to produce ocular lesions. LPV was more antigenic than SPV and produced higher antisera titers; sera from animals inoculated by corneal infection produced high antibody titers in 14 days, while the i.p. inoculation was slower in producing antibodies.

1058 RNA SYNTHESIS IN CELLS INFECTED WITH HERPES SIMPLEX VIRUS: III. ABSENCE OF VIRUS-SPECIFIC ARGINYL- AND SERYL-tRNA IN INFECTED Hep-2 CELLS. (E.) Morris, V. L. (Dept. Microbiol., U. Chicago, Ill.), E. K. Wagner and B. Roizman. *J Molec Biol* 52(2):247-263, 1970.

Experiments were designed to test the ability of herpes simplex virus to specify its own arginine- or

serine-specific transfer RNA in human epidermoid carcinoma no. 2 cells (HEp-2) utilizing co-chromatography and hybridization competition tests. Arginyl-tRNA reached a maximal level after 15 min at 37°C and remained unaltered for at least 15 additional min, showing that little or no RNase was present. Hydrogen ion concentration and the ratio of magnesium ion:ATP did not alter populations of tRNA charged with arginyl-tRNA synthetase. No differences in elution profiles of arginyl-tRNA extracted from infected and uninfected cells determined from inspection of $^3\text{H}/^{14}\text{C}$ ratios was noted. Chromatographic properties of seryl-tRNA were indistinguishable from those of the corresponding tRNA's of uninfected cells. Approximately 2 moles of purified 4 S RNA of molecular wt 25,000 daltons extracted from infected cells hybridized with 1 mole of viral DNA; the annealed nucleotide sequences were homologous to those found in nuclear RNA of molecular wt 50,000 daltons or higher. Arginine-specific or serine-specific tRNA could not be shown to anneal to viral DNA. If viral arginine- and serine-specific tRNA are coded in HEp-2 cells, they are made in amounts insufficient to be detected.

- 1059 LETHAL RETICULOPROLIFERATIVE DISEASE INDUCED IN *CEBUS ALBIOFRONS* MONKEYS BY *HERPESVIRUS SAIMIRI*. (E.) Melendez, L. V. (Harvard Med. Sch., Southboro, Mass.), R. D. Hunt, M. D. Daniel, C. E. O. Fraser, F. G. Garcia and M. E. Williamson. *Int J Cancer* 6(3):431-435, 1970.

A reticuloproliferative disease induced in monkeys by *Herpesvirus saimiri* was investigated in 4 ring-tail cinnamon monkeys. Monkeys were injected i.m. with 0.5 ml of undiluted Cebus isolate virus; 6 months later undiluted *H. saimiri* were inoculated into the monkeys (0.5 ml, i.m.). All monkeys died between 18-20 days after *H. saimiri* injection. Sera were assayed for viral antibodies and no antibodies to either Cebus isolate virus or *H. saimiri* were found. No cytopathic effect was observed in owl monkey cultures inoculated with liver and kidney samples from monkeys injected with Cebus isolate virus and *H. saimiri* virus. A cellular infiltrate was found at autopsy in the liver, lung, thymus and lymph nodes of each monkey and in the spleen and pancreas of certain of these animals. The infiltrate was composed primarily of round, polygonal to fusiform cells with leptochromatic nuclei and eosinophilic cytoplasm, and were thought to be reticulum cells. Multinucleated giant cells were occasionally observed in the reticulum cell sheets in the thymus. These reticulum cell infiltrates resembled reticulum cell sarcoma. It appeared that the reticuloproliferative disease in these monkeys was induced not by Cebus isolate virus but by *H. saimiri*.

- 1060 TEMPERATURE-SENSITIVE MUTANTS OF HERPES SIMPLEX VIRUS. (E.) Schaffer, P. (Baylor Coll. Med., Houston, Tex.), V. Vonka, R. Lewis and M. Benyesh-Melnick. *Virology* 42(4):1144-1146, 1970.

Human embryonic lung fibroblast cultures were infected with wild-type herpes simplex virus and in-

cubated with the mutagen 5-bromodeoxyuridine in concentrations of 0.3-5.0 µg/ml culture for 48 hr. Treated cultures were frozen and thawed 3 times and centrifuged, and the supernatants were stored at -90°C. These mutagenized viral stocks were seeded on human embryonic lung fibroblast monolayers, and the growth increments of plaques were observed. Plaques which did not increase in size during 24 hr were regarded as potential mutants. Of 708 plaques isolated, 22 were shown to have greatly decreased capacity for growth at 40° when compared to wild-type virus. Wild-type virus showed virus titers of 4.2×10^7 plaque-forming U at 40°, while representative mutants had titers of 1.0×10^2 and 4.5×10^2 . All mutants except one exhibited multiplicity-dependent leakiness, and all were significantly neutralized by herpes simplex virus antiserum.

- 1061 GENITAL HERPESVIRUS HOMINIS TYPE 2 INFECTION: AN EXPERIMENTAL MODEL IN CEBUS MONKEYS. (E.) Nahmias, A. J. (Emory U. Sch. Med., Atlanta, Ga.), W. T. London, L. W. Catalano, D. A. Fuccillo, J. L. Sever and C. Graham. *Science* 171(3968):297-298, 1971.

Attempts were made to infect the genital organs of female monkeys of 3 species with herpesvirus hominis type 2. The virus was originally obtained from a female patient and had undergone 3 or 4 passages in tissue cultures of rabbit kidney. Cotton pellets were impregnated with undiluted virus (titers of $10^{5.5}$ - $10^{6.5}$ TCID₅₀) which were implanted in the vaginal vault. Infections could not be produced by this method in squirrel monkeys or rhesus monkeys; however 10 cebus monkeys (*Cebus albifrons*) were successfully infected. Virus could be detected by immunofluorescence in cervico-vaginal swabs from 3-16 days after inoculation in 3 monkeys. All monkey had inflamed vaginas and cervixes, and 7 had herpetic like vesicles or ulcers on the vulvas. Four monkeys developed perineal and finger lesions from which virus could be recovered. Genital reinfection attempts with the same herpesvirus hominis strain were successful in 3 monkeys. All monkeys had neutralizing viral antibody in the serum. The infection of cebus monkey by herpesvirus hominis may be a valuable model for human infection by this virus.

- 1062 HERPESVIRUS ANTIGENS ON CELL MEMBRANES DETECTED BY CENTRIFUGATION OF MEMBRANE-ANTIBODY COMPLEXES. (E.) Roizman, B. (Dept. Microbiol. U. Chicago, Ill.) and P. G. Spear. *Science* 171(3968):298-300, 1971.

The binding of antiviral antibodies to cell membranes was investigated in herpes viruses. It was found the glycoproteins specified by herpes viruses bind to cell membranes and appear in the virion envelope. When antiviral antibodies were incubated with purified smooth membranes of human epidermoid carcinoma cells infected with virus, an increase was observed in the density of the membranes which was revealed in sucrose density gradient centrifugation. While the densities of untreated membranes were 1.08 g/cm³, densities of cell membranes treated with antibodies were as high as

1.6 g/cm³. Antiviral antibody did not increase the density of uninfected cell membranes, and saline and normal rabbit serum did not change the densities of infected or of uninfected cell membranes. It was suggested that viral antigens, probably the glycoproteins specified by the virus, were located on the surface of infected cell membranes, and were bound strongly enough to withstand the membrane isolation procedures.

1063 DETECTION IN CHICKEN AND HUMAN SERA OF ANTIBODY AGAINST HERPES TYPE VIRUS FROM A CHICKEN WITH MAREK'S DISEASE AND EB VIRUS DEMONSTRATED BY THE INDIRECT IMMUNOFLUORESCENCE TEST. (E.) Iwamoto, M. (Res. Inst. Microbial Dis., Osaka U., Japan), K. Ono, S. Tanabe, T. Doi and S. Kato. *Biken J* 13(3): 205-212, 1970.

Antibodies to chick herpes type virus antigen were found in sera from chickens with Marek's disease, healthy chickens and healthy humans; anti-Epstein-Barr virus antibody titers in sera from chickens with Marek's disease and in healthy humans were also examined. Herpes type virus antigens were prepared in duck embryo fibroblasts infected with herpes type virus from a chicken with Marek's disease. High antibody levels against chick herpes type virus antigens were found in sera from chickens with viremia of chick herpes type virus, in sera from chickens with Marek's disease, and in sera from chickens inoculated with herpes type virus. All sera from chicks in these conditions aged from 0-10 days had antibodies, while chicks aged from 11-30 days had lower incidences of antibody. Antibody levels increased in chicks aged 30-61 days. Antibody titers in the older chicks were at levels greater than or equal to 1:640. However, sera from chicks free of specific pathogen and negative COFAL tests had low incidences of antibody; sera from 11 specific pathogen-free chicks raised in vinyl isolators showed no antibody. Most sera prepared from healthy human subjects contained antibody activity against chick herpes type virus. The anti-Epstein-Barr virus antibody titers in sera from chickens were also tested using indirect immunofluorescent techniques; some chick sera were Epstein-Barr virus antibody-positive, but titers of antibody were not so high as titers of herpes type virus antibody. Antibodies to herpes type virus in sera from 7-18-day-old chicks may have been derived from maternal antibody stores.

1064 POLYPEPTIDES OF AVIAN RNA TUMOR VIRUSES: I. ISOLATION AND PHYSICAL AND CHEMICAL ANALYSIS. (E.) Bolognesi, D. P. (Max Planck Inst. Virus. Res., Tübingen, Germany) and H. Bauer. *Virology* 42(4):1097-1112, 1970.

The protein components of avian myeloblastosis virus were extracted with phenol and SDS and examined electrophoretically. Major components with molecular wt ranging from 13,000-28,000 and minor components with molecular wt well in excess of these were found. Four major bands were detected by specific staining and were present in viruses from subgroups A and B. A component protein of molecular wt 15,000 showed unusual staining properties with amido black stain, but incorporated radioactive amino acids poorly.

Another component (23,000 molecular wt) tended to aggregate, but this tendency was eliminated by treatment with dithiothreitol. The component proteins of higher molecular wt included one (115,000 molecular wt) which was associated with material which could be stained with polysaccharide and which was strongly labeled with ¹⁴C-glucosamine. A similar component was found in preparations which contained the type-specific antigen of the avian myeloblastosis virus.

1065 POLYPEPTIDES OF AVIAN RNA TUMOR VIRUSES: II. SEROLOGICAL CHARACTERIZATION. (E.)

Bauer, H. (Max Planck Inst. Virus Res., Tübingen, Germany) and D. P. Bolognesi. *Virology* 42(4):1113-1126, 1970.

The antigenicity of various protein components of avian myeloblastosis virus were investigated following extraction of virus with phenol and SDS and electrophoresis of the protein components on acrylamide gels. This process did not result in any significant loss of group-specific complement-fixing antigenicity, and the antigenic properties of the major viral polypeptides could be ascertained. Four major components were detected in complement fixation tests with group-specific rabbit and group-specific hamster antisera. The different protein components appeared to be immunologically distinct, and their differences were further accentuated in agar gel double diffusion tests. Viral components 1 and 2 were immunogenically weak, while components 3 and 4 were more antigenic. Component 4 appeared to be identical to a material shown previously to have the properties of a group-specific antigen. Much of the type-specific antigenicity was lost in the treatment of the virus; however, it was possible to test various fractions remaining after electrophoresis. Most of the virus envelope antigen was found in the region of the main glycoprotein component of the virus, but no correlation could be demonstrated between this antigenic activity and the polysaccharide staining material.

1066 DIFFERENCES BETWEEN THE RIBONUCLEIC ACIDS OF TRANSFORMING AND NON-TRANSFORMING AVIAN TUMOR VIRUSES. (E.) Duesberg, P. H. (Dept. Molec. Biol., U. California, Berkeley) and P. K. Vogt. *Proc Nat Acad Sci* 67(4):1673-1680, 1970.

Differences in the RNAs of a transforming avian sarcoma virus B77 and its nontransforming derivatives both in their native forms and after heat dissociation into subunits are reported; the nontransforming viruses were isolated after UV irradiation of B77. The viruses were grown in suspension cultures of myeloblasts from leukemic chickens, and viral RNA was labeled with ³H-uridine and ³²P-H₃PO₄. The RNAs of the nontransforming virus were found to migrate slightly faster than RNA of B77 with gel electrophoresis. Electropherograms of the heat-dissociated RNAs demonstrated both classes of RNA subunits *a* and *b* in B77, but in 2 of the nontransforming viruses, NT B77 clone 5 and NT B77 clone, the class *a* subunit was absent. The absence of class *a* RNA may be related to the inability of these viruses to transform chick embryo

fibroblasts in tissue culture, or its presence may be merely the consequence of the transformed state of the cell.

- 1067 INABILITY TO PREDICT MAMMARY TUMORIGENESIS IN STRAIN A MICE FROM PRESENCE OF MAMMARY TUMOR VIRUS OR ANTIGEN IN THE MILK. (E.) Heston, W. E. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), W. T. Hall, G. Vlahakis, J. Charney and D. H. Moore. *J Nat Cancer Inst* 45(5):937-940, 1970.

The correlation of development of mammary tumors and the presence in mammary milk of mammary tumor virus (MTV) and of MTV antigen was investigated in breeding female mice of the A/He strain in which the incidence of mammary tumors is about 40%. The presence of MTV in milk was tested for by an alveolar nodule test and MTV antigen by a microimmunodiffusion test. Full agreement was not found between the results of the MTV tests and the results of the MTV antigen tests. Of 35 tested samples, 18 were MTV antigen-positive and 17 were antigen-negative. Virus-presence tests were run only on 19 samples; of these samples 9 were shown to contain virus antigen and 10 did not contain virus antigen. Fourteen of the 19 samples contained virus, however, producing hyperplastic alveolar nodules at milk dilutions of from 10^{-1} - 10^{-4} . Eight of the virus-containing samples were also antigen-positive; of the 5 samples which did not contain virus, 3 were also antigen-negative, but 2 were antigen-positive. The presence in milk of virus and/or antigen could not be used to predict subsequent development of mammary tumors. Twelve of the tested mice developed tumors (34%). Seven of these were virus antigen-negative, and 9 of the antigen-positive mice remained tumor-free for the duration of the experiment. Seven of the mice which developed mammary tumors were virus-positive, but 2 females which developed tumors were virus-negative. Seven virus-positive mice failed to get tumors. Apparently, mammary tumorigenesis in this mouse strain is determined by factors other than the presence of MTV in the milk.

- 1068 DISSOCIATION BETWEEN CELL CONVERSION INDUCED BY MOUSE SARCOMA VIRUS AND PRODUCTION OF INFECTIOUS VIRUS. (E.) Guillemain, B. (Hosp. St. Louis, Paris, France), J. Laumond, C. Godard and M. Boiron. *J Gen Virol* 10(1):91-93, 1970.

The dependence on virus multiplication of cell conversion by mouse sarcoma virus isolate (MSV) was investigated by treating infected cell cultures with 5-fluorouracil to block this multiplication. Monolayers of mouse cells were infected with MSV, and 5-fluorouracil was added to the cultures in differing concentrations. The number of foci present decreased as the concentration of 5-fluorouracil increased; at a concentration of 0.0125 $\mu\text{g/ml}$, the percent of foci counted was about 80%, while at concentrations of 5-fluorouracil of 0.8 $\mu\text{g/ml}$, the percent of foci counted was 0.5%. In this experiment, the multiplicity of introduction of the virus was 2×10^{-4} FFU/cell and the amount of 5-fluorouracil needed to give 99.9% focus inhibition was about 1.0 $\mu\text{g/ml}$. For higher multiplicities of introduc-

tion, the dose of 5-fluorouracil needed to fully inhibit focus formation was higher. At doses of 25 μg of 5-fluorouracil cell multiplication was inhibited, and the rate of nucleic acid synthesis was reduced to 10% of normal and was evenly distributed between RNA and DNA. These findings suggest that cell conversion induced by MSV is related to an effect which occurs before replication of the virus.

- 1069 ENHANCEMENT OF MURINE SARCOMA VIRUS (MOLONEY) INFECTION IN MICE BY GUAROA VIRUS. (E.) Turner, W. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), W. Gibson and M. A. Chirigos. *Cancer Res* 30(11):2645-2651, 1970.

Temporal studies are presented in this report which show the potentiating effects of dually infecting mice with murine sarcoma virus (Moloney) and Guaroa virus. Mice were inoculated by various routes with Guaroa virus prior to or simultaneously with intramuscular inoculation of murine sarcoma virus (Moloney) and the time intervals noted with respect to increased incidence of death. Potentiation was most pronounced in mice inoculated with Guaroa virus three days prior to and simultaneously with murine sarcoma virus (Moloney) and resulted in earlier tumor deaths. Guaroa virus showed no effect on the humoral or cellular immune response nor did it produce significantly different titers of interferon from noninfected mice. The mechanism whereby Guaroa virus, a nononcogenic arbovirus, enhances murine leukemia in mice is not yet known.

- 1070 RESCUE OF MURINE SARCOMA VIRUS GENOME IN MIXED CULTURES OF "NON-PRODUCER" HAMSTER TUMOUR CELLS AND HELPER VIRUS CARRIER CELL LINES. (E.) Chang, S. S. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), R. V. Gilden and R. J. Huebner. *J Gen Virol* 10(1):107-110, 1970.

The rescue of the Moloney isolate of murine sarcoma virus (MSV) from non-producer hamster tumor cells (HT-1) by cocultivation with various murine leukemia virus (MLV)-carrier cells of mouse and hamster origin (F4 and F5 from Rauscher pseudotype MSV-transformed foci of mouse embryo cells, the Walkersville cell line (WH-1) from mouse tumor carrying a wild type MLV, and the RHT cell line from RLV-transformed hamster embryo cells) is described. Co-cultivation of HT-1 and F4 resulted in MSV recovery in more than 20 attempts, while mixed cultures of HT-1 with F5, WH-1, or RHT cells yielded MSV only once or twice in 3-5 attempts. The differences in rescue efficiency were related to the infectivity of the helper viruses for mouse embryo cell (except with F5). A 100-fold decrease in MSV rescue resulted from each 10-fold decrease in the number of F4 cells, and excess (2×10^5) HT-1 cells decreased the yield of MSV. A reproducible growth curve for MSV retrieval was obtained with optimal numbers of HT-1 (8×10^4 cells) and F4 (8×10^5 cells).

1 STRUCTURAL PROTEINS OF KILHAM RAT VIRUS.
(E.) Salzman, L. A. (Natl. Inst. Allerg.
ect. Dis., Natl. Inst. Hlth., Bethesda, Md.) and
L. White. *Biochem Biophys Res Commun* 41(6):1551-
56, 1970.

The component proteins of the Kilham rat virus were
investigated and described. Virus was cultured in
rat nephroma cell line at an input multiplicity
5 plaque-forming U/cell. Viral proteins were
separated by the addition to the culture of a mixture
of ^3H - or ^{14}C -L-amino acids, and protein subunits
were separated by electrophoresis on polyacrylamide
gels and by agarose gel filtration in 6M guanidine-
HCl. Electrophoresis of radioactive Kilham virus
proteins showed 3 major bands of radioactivity (A,
B, and C), which were found to have molecular wt of
100,000 daltons, 62,000 daltons and 55,000 daltons,
respectively. Component A made up 13.1% of the total viral
protein, component B made up 75.5%, and component C,
11.4%. Hemagglutination tests revealed that compo-
nent B showed strong hemagglutination activity as well
as strong hemagglutination inhibition. It was con-
cluded that component B was probably a capsid pro-
tein.

2 IMMUNOLOGICAL STUDIES ON A "SPONTANEOUS-
LY" TRANSFORMED CELL LINE OF SWISS MOUSE
EMBRYONAL FIBROBLASTS: A POSSIBLE VIRAL ONCOGENESIS.
(E.) Vernekar, S. D. (Cancer Res. Inst. Tata Mem.
Hospital, Parel, Bombay, India), S. G. Gangal and K. J.
Sinha. *Indian J Exp Biol* 8(1):7-10, 1970.

Culture of mouse embryo fibroblasts which had un-
dergone spontaneous malignant transformation was
examined for antigens to virus. The cell line,
maintained as a plasma clot culture, produced tumors
in 73% of mice as early as the 15th passage *in vitro*.
Cells were thought to possess 100% tumorigenicity
at an early stage. Accordingly, the cultures were
tested with antisera prepared from a heterologous
rabbit serum in order to confirm the possibility
of a viral etiology for the malignant transformation.
Tumor and cell extracts from the test cultures re-
acted well in complement fixation tests with anti-
virus; antigens were selected in such a way as to
exclude known cross-reactivities. High complement
fixing titers were obtained with tumor extracts test-
ed with unabsorbed rabbit antisera (titers of 126).
High complement fixing titers were also observed
in tumor extract cells were tested with rabbit
anti-adenovirus 12 antisera (titer of 512). Anti-
virus reactions with the heterologous rabbit anti-
sera were considered to be specific for an antigen
of the transformed malignant cells not found in nor-
mal tissue of the species and strain. The findings
presently suggested an unknown viral infection as
the cause of malignant transformation in the test
cell system.

3 PROPAGATION IN HUMAN CELLS OF A FILTER-
ABLE AGENT FROM THE ST FELINE SARCOMA.
(E.) Chang, R. S. (Dept. Med. Microbiol., U.
California, Davis), H. D. Golden and B. Harrold.
Virology 6(5):599-603, 1970.

A filtrate prepared from Snyder-Theilen feline sar-
coma (ST feline sarcoma) was propagated in human
fibroblast cultures from embryonic or sarcomatous
tissues. Seven of the 19 human cell lines tested
showed morphological alteration and released focus-
forming activity, and 2 lines showed alterations
but did not release focus-forming activity; 11 cell
lines neither showed morphological alterations nor
released focus-forming activity. A cell line de-
rived from an osteosarcoma at the 21st passage con-
sistently showed the most extensive morphological
changes on inoculation of feline cell cultures.
Altered cells were enlarged and hyper-refractile;
they stained intensely with hematoxylin. These
cells did not form visible foci, nor did they assume
a criss-cross pattern. Altered cells did not
divide and were motile. Cells derived from osteo-
sarcomas below the 10th passage level consistently
failed to show focus-forming activity. No inter-
feron activity was detected in the sarcoma filtrate
and in culture fluids from 8 cell lines. Fibro-
sarcoma was induced in newborn kittens by inocu-
lation with the fluid from 2 human fibroblast cul-
tures which had been treated with ST feline sarcoma
filtrate 4 and 14 wk before.

1074 INDUCTION OF PAPILLOMAS IN RABBITS WITH
NUCLEIC ACID EXTRACTS FROM Vx7 CARCINOMAS.
(E.) Ito, Y. (Aichi Cancer Ctr., Nagoya, Japan).
Brit J Cancer 24(3):535-541, 1970.

The ability of nucleic acid extracts from transplanta-
ble carcinomas Vx2 and Vx7 (one of the series of
transplantable carcinomas of the Shope papilloma-
carcinoma sequence) to induce tumors in rabbits was
investigated. The Vx7 and Vx2 tumors had been main-
tained in domestic rabbits for 111 and 203 genera-
tions, resp. Vx2 carcinomas were more invasive than
Vx7 carcinomas in the donor rabbits, the former tu-
mor type showing metastases to the lymph nodes in
109 cases, and the latter tumor metastasizing to
this site in only 18 cases. Histologically, Vx7 tu-
mors were characteristically squamous cell type car-
cinomas, while Vx2 were entirely anaplastic. At 5-7
wk after administration of nucleic acid extracts
from Vx7 tumors to rabbits, papillomatous growths
arose at a number of inoculation sites; numbers of
papillomatous growths/number of inoculation sites
ranged from 12/84-6/84. The majority of tumors in-
duced by nucleic acid from Vx7 tumors regressed af-
ter a certain period of growth on the rabbits' skin.
One papilloma underwent malignant conversion to the
status of a squamous cell carcinoma in the course of
77 wk. Efforts to induce tumors with nucleic acid
preparations from Vx2 tumor were entirely unsucces-
ful. Efforts to detect Shope papilloma virus in nu-
cleic acid-induced tumors revealed only 1 possibly
virus-associated excrescence in 400 inoculation sites.

1075 SOME FEATURES OF VIRAL RETICULUM CELL
SARCOMA IN MICE. (Rus.) Bergolits, V. M.
(P. A. Herzen Res. Inst. Oncol., Moscow), V. S.
Ter-Grigorov and O. Ya. Moskvkina. *Vop Onkol*
16(9):53-58, 1970.

Several features of viral reticulum cell sarcoma (RS) were investigated in CC 57BR/Mv, C57BL/G, C3HA and BALB/C mice and in Wistar rats. Virus preparations such as cell-free tumor nodule extracts or heparinized plasma from leukemic mice with RS were used. Cytologically detectable early stages of RS were noticed in 53% of the CC57BR mice at 1-1.5 months following i.v. or i.p. injection of either preparation; advanced forms of RS seen at this time (20%) increased to 75% at 2-3 months. The presence of leukemogenic virus in the plasma of these mice was proved in 10^{-3} - 10^{-4} dilutions. Large amounts of viral particles, 140-150 m μ in diameter were prevalent in the intercellular spaces as seen by electron microscopy. The possibility of RS virus cultivation *in vitro* (segments of RS tissue in embryonic tissue-containing plasma and medium 199 plus 10% bull serum) was proved by i.v. inoculation with cell-free liquid phase after 11 and 47 days of culture which induced leukemia in 2 of 12 mice 35 days following contamination and RS in 4 of 4 mice killed 4 months after inoculation, resp. Transmittance of RS from CC57BR mice (by cell-free extract inoculation or cell transplants) was possible only into C57BL/6 mice having a closely related genotype with the CC57BR mice; however, the occurrence of RS appeared irregular and after 5-14 month-long latency periods. Inoculation of 16 newborn Wistar rats with RS material induced leukemia in 1 rat of the 16-19 month-old animals. Suppression of resistance to RS virus was achieved with Freund's adjuvant in the BALB/c and CC57 W lines. Group-specific antigen was found to be present in RS in amounts similar to those found in Gross-, Rauscher-, Friend- and Moloney-virus-induced leukemias. Attempts to induce antiRS immunity in CC57BR mice by preliminary inoculation with low virus dosages failed; tumor growth stimulation took place instead. Mouse RS is concluded to be an appropriate model for experimental investigation.

- 1076 CHARACTERIZATION OF THE COMPLEMENTARY NUCLEAR RNA OF MURINE SARCOMA-LEUKEMIA VIRUS. (E.) Biswal, N. (Baylor Coll. Med., Houston, Tex.) and M. Benyesh-Melnick. *Virology* 42(4):1064-1072, 1970.

This study is an investigation into the sedimentation behavior of the viral RNA-nuclear RNA hybrids and the complementarity of the base composition of heat dissociated RNA (37 S) of murine sarcoma-leukemia virus hybridized with 32 P-labeled heat denatured nuclear RNA of cells infected with murine sarcoma-leukemia virus. Three distinct sedimenting species of RNA hybrids were formed, 18 S, 10.5 S and 4 S. The 18 S hybrid showed virus-specificity and an overall base composition similar to the viral RNA, indicating it may be a true specific product of hybridization of the viral RNA with its complement in the nucleus of the transformed cell. Murine sarcoma-leukemia virus RNA may possibly replicate like the RNA of nononcogenic viruses.

- 1077 RELATIONSHIP BETWEEN GROWTH RATE, CELL VOLUME, CELL CYCLE KINETICS, AND ANTIGENIC PROPERTIES OF CULTURED MURINE LYMPHOMA CELLS. (E.)

Cikes, M. (Karolinska Inst., Sch. Med., Stockholm, Sweden). *J Nat Cancer Inst* 45(5):979-988, 1970.

Mechanisms underlying the expression of H-2 and Moloney leukemia virus-induced surface antigens of murine lymphoma cells during the growth cycle were clarified through the use of indirect membrane immunofluorescence testing and complement-dependent antibody-mediated cytotoxic sensitivity testing. A rapid fall in cytotoxic sensitivity was shown in cells during the first 48 hr after seeding followed by a rise until 148 hr when a decline was again noted, with a similar pattern established for indirect membrane immunofluorescence reactivity. Cell volume of the whole population indicated a marked shift toward small cell populations between 48 and 148 hr, with the larger cells showing a growth rate higher than that of smaller cells. Life cycle analysis at different intervals during the growth cycle showed that variations in duration of population doubling time influenced the length of the G1 period mainly. Variations in expression of surface antigens on cultured cells during the growth cycle can be considered the result of limiting periods of synthesis of membrane antigenic receptors. Hence, variations in concentration of surface antigens on cultured mouse lymphoma cells may result from sequential repression and derepression of genes specifying the synthesis of cell-surface antigens.

- 1078 A STUDY OF THE ONCOGENIC AND INFECTIOUS FUNCTIONS OF ROUS SARCOMA VIRUS. (Fr.) Golde, A. (Fac. Sci. Orsay, France). *Bull Cancer* 57(2):195-216, 1970.

Oncogenic action and reproduction capability of Rous virus *in vitro* were investigated on chick embryo fibroblast cultures with various mutants of the Schmidt-Ruppin strain by varying the conditions of cell culture, promoting one or the other of the investigated functions. Two defective mutants of the Schmidt-Ruppin strain were obtained by exposure to 3000 kr of 60 Co emitting γ -radiations; one mutant had oncogenic properties but was unable to reproduce itself within the transformed cell culture, and the other was a noncarcinogenic mutant capable of reproduction. The neoplastic nature of the cells transformed by the oncogenic mutant was confirmed by their transplantability into eggs with 10 day-embryos; these cells did not release virions and were referred to as NP cells. The non-oncogenic mutant was referred to as NT gamma mutant and produced no morphological alterations in chick embryo fibroblasts. However, these virions contained a group specific (gs) antigen characteristic for avian oncogenic viruses. The occurrence of these 2 different mutants suggested that oncogenicity and reproduction were coded by different independent portions of the viral genome; it was postulated that the viral RNA molecule could be constituted of several independent subunits. Variations of culture conditions indicated that the infection and transformation efficacy of Schmidt-Ruppin and Bryan mutants was not cell age dependent. These properties seemed to be affected by the number of monocellular layers (degree of confluence)

the moment of infection. A cellular density of monolayers appeared to be the threshold when cell transformation would no longer occur, although infection and virion production were still possible. The factor of cellular density apparently did not affect infectivity and virion productivity but did inhibit the reading of the viral information needed to induce cell transformation.

79 ADENINE NUCLEOTIDE DEPENDENT ULTRASTRUCTURAL SURFACE ALTERATIONS IN TRANSFORMED BHK 21/13 CELLS. (Fr.) Torpier, G. (Inst. Pasteur, Lille, France) and L. Montagnier. *Int J Cancer* 6(3):529-535, 1970.

Adenine nucleotide-dependent surface cell alterations were studied by means of ruthenium red staining in BHK 21/13 cell cultures subjected to Rous or polyoma virus transformation. The cell clones were grown in glass bottles on ETC 10 media with 10% bactotryptose phosphate and 10% calf serum treated with 5 µg/ml of streptomycin. The role of nutritive factors was studied on Eagle BME media treated with 10% calf serum and 3 mg glucose/ml (basic media). The cell cultures transferred from the ETC 10 media were kept for 48 hr in the basic media until the end of their exponential growth before being subjected to ultrastructural investigation. Electron microscopy revealed a thick ruthenium red staining layer on the external surface of the cytoplasmic membrane in both normal and transformed BHK 21/13 cells; this layer was thicker in transformed cells grown wholly on ETC 10 media. In normal cells cultivated on basic media lacking bactotryptose for 48 hr before fixation, no differences were seen in the thick layer compared to the clones grown on ETC 10 media. Addition of ribosomal RNA (200 µg/l) or of pancreatic ribonuclease-hydrolyzed RNA or of adenine nucleotides such as adenosine 3'- or 5'-phosphate (300 µM/ml) produced considerable thickening of the ruthenium red staining layer in all transformed clones. UMP, CMP and GMP had no such effects. AMP had less effect in the presence of bactotryptose and no effect in the original BHK 21/13 clone. The mechanism of action of adenine nucleotides in modifying the cell surface may possibly be the same in all transformed cells; this mechanism seems to be associated with the initial changes related to transformation of these cell clones by the oncogenic viruses.

80 STUDIES ON NUCLEIC ACIDS IN ROUS SARCOMA VIRUS-INDUCED MOUSE ASCITES SARCOMA CELLS. DISTRIBUTION AND ELECTRON MICROSCOPY OF NUCLEIC ACIDS IN SUBCELLULAR FRACTIONS AND CIRCULAR DNA IN MITOCHONDRIAL FRACTIONS. (E.) Yamamoto, G. (Okayama U. School of Medicine, Japan) and T. Oda. *Acta Med Okayama* 25(3):287-302, 1970.

The distribution of nucleic acids in subcellular fractions (differential centrifugation) of mouse ascites sarcoma cells (SR-C3H) induced by Rous sarcoma virus and of normal C3H mouse liver was studied, and the extracted nucleic acids were examined by electron microscopy. The RNA/DNA ratios were 2.3 and 3.7 in the homogenates and 0.34 and 0.56 in the

nuclear fractions of SR-C3H cells and liver cells, resp. DNA and RNA contents of SR-C3H mitochondria (3.1 and 24 µg/mg protein, resp.) were higher than in liver mitochondria, but the mean value of the contour length of circular DNA molecules was smaller in SR-C3H mitochondria (4.88 µ) than in liver mitochondria (5.08 µ). Microsomal and supernatant fractions of both the SR-C3H cells and liver contained DNA equivalent to 3-6% of the RNA content; the SR-C3H supernatant fraction seemed particularly high in DNA content, and electron micrographs revealed fibrous linear structures (double-stranded nucleic acids) in the SR-C3H supernatant but not in the liver supernatant.

1081 DEOXYRIBONUCLEIC ACID POLYMERASE ASSOCIATED WITH ROUS SARCOMA VIRUS AND AVIAN MYELOBLASTOSIS VIRUS: PROPERTIES OF THE ENZYME AND ITS PRODUCT. (E.) Garapin, A. C. (Dept. Microbiol., U. California, San Francisco), J. P. McDonnell, W. Levinson, N. Quintrell, L. Fanshier and J. M. Bishop. *J Virol* 6(5):589-598, 1970.

A DNA polymerase associated with Rous sarcoma virus and avian myeloblastosis virus is identified in preparations of the viruses purified through treatment with a nonionic detergent. DNA polymerase activity was dependent upon concentration of detergent as a function of protein concentration of the virus suspension; catalysis of the synthesis of DNA persisted for at least 6 hr at an optimum temperature of 45°C and showed an 8- to 10-fold reduction of activity when pretreated with ribonuclease, a 2- to 3-fold inhibition in the presence of actinomycin D and only slight inhibition with Rifampin. Sedimentation analysis of the early and late products showed a DNA which cosedimented with 70 S viral RNA at neutral pH (30 min) and a mixture of DNA-RNA hybrids and double-stranded DNA (4 hr); at 8 hr, the major product was double-stranded DNA.

1082 THE GROWTH CAPACITY OF NORMAL AND ROUS-VIRUS-TRANSFORMED CHICKEN FIBROBLASTS IN VITRO. (E.) Ponten, J. (Wallenberg Lab., Uppsala, Sweden). *Int J Cancer* 6(3):323-332, 1970.

The proliferation dynamics of chicken embryo cell cultures transformed by Rous sarcoma virus, Schmidt-Ruppin strain (RSV-SR), was compared with that of normal cells. RSV-SR-transformed cells had a decreased average population doubling time (15 hr vs 21 hr for normal cells), and increased maximal terminal cell density (70×10^4 cells/cm² vs 35×10^4 for normal cells) and a shorter life span (10-15 passages compared to 20-27 passages in normal cells). The cumulative cell number of the transformed cells (10^9) was considerably lower than that of untransformed cells (10^{12}), and no established cell lines were developed. RSV-SR-transformed cells from one sex cocultivated with normal cells of the opposite sex resulted in a rapid transformation of the normal cells with the proportion of dividing cells from the originally transformed cells decreasing as the newly transformed cells became dominant. Apparently avian Rous sarcoma proliferates only if normal cells are constantly transformed and added to the pool of transformed or neoplastic cells.

- 1083 STUDIES ON THE LOSS OF GROWTH INHIBITION IN CELLS INFECTED WITH ROUS SARCOMA VIRUS. (E.) Weiss, R. (Dept. Anat. Embryol., U. Coll., London, England). *Int J Cancer* 6(3):333-345, 1970.

The loss of growth inhibition (density-dependent and anchorage-dependent growth) was studied in chick embryo cells infected with Rous sarcoma virus (RSV). Transformed cells and newly infected cells were capable of proliferating in soft gel suspension and among densely populated normal cells. Plating freshly infected cells on crowded mouse embryo cells or 3T3 cells inhibited cell transformation and viral replication, but the majority of infected cells lost their sensitivity to inhibition 6 hr after infection, and all cells were released from inhibition after 12 hr. The quantity or envelope properties of virus released from the cell surface did not influence the changes in proliferative behavior of transformed cells, and preinfection with a Rous-associated virus (RAV) did not alter the density-dependent cell transformation by RSV. Freshly infected cells maintained in the inhibited state for 6 days were capable of transforming when replated to sparse conditions. Cell transformation was dependent on cell proliferation but RSV infection could not initiate the cell division cycle in crowded monolayers.

- 1084 CHROMOSOMAL ANALYSIS OF PRIMARY AND METASTATIC ROUS SARCOMAS IN THE RAT. (E.) Mitelman, F. (Inst. Path. U. Lund, Sweden) and J. Mark. *Hereditas* 65(2):227-236, 1970.

The chromosomes of 13 primary and 4 metastatic Rous Sarcomas in the rat were studied in sections taken directly from the tumors. The stemline number was 42 in 11 of the primary tumors and in 3 of the metastatic tumor cases, but the spread of the overall chromosomes showed a positive skewness. Polyploid cells were uncommon (approximately 1%), and hyperploidy was the most common heteroploid pathway (24% in the primary tumors and 38% in the secondary tumors) while pseudoploidy was the second common pathway (15% in the primary and 50% in the metastatic tumors). Trends towards a nonrandom chromosomal engagement were observed.

- 1085 PROTEINS OF AVIAN TUMOR VIRUSES WITH DIFFERENT COAT ANTIGENS. (E.) Robinson, W. S. (Stanford U. Sch. Med., Calif.), P. Hung, H. L. Robinson and D. D. Ralph. *J Virol* 6(5):695-698, 1970.

The protein components of 2 avian tumor viruses with distinct type-specific envelope antigens were examined by gel electrophoresis. The viruses which were studied, Rous-associated virus type 1 (RAV-1) and Rous sarcoma virus type $\beta(0)$ [RSV $\beta(0)$], had identical isoelectric points, as demonstrated by isoelectric focusing. Coelectrophoresis of ^{14}C -amino acid-RSV $\beta(0)$ and ^3H -amino acid RAV-1 in a polyacrylamide gel containing sodium dodecyl sulfate permitted the identification of 8 labeled protein components in the viruses, numbered P1-P8. P1,

a slowly-moving protein, was the major protein in RSV $\beta(0)$, while P2 was the major protein in RAV-1. The findings, which indicate that these 2 viruses of different type-specific surface antigens have glycoprotein components with differing mobilities in sodium dodecyl sulfate gel electrophoresis, suggest that the glycoproteins are related to the type-specific antigen.

- 1086 RECOVERY OF A NEW VIRUS FROM APPARENTLY NORMAL CHICK CELLS BY INFECTION WITH AVIAN TUMOR VIRUSES. (E.) Hanafusa, T. (Publ. Hlth. Res. Inst. City New York, N.Y.), H. Hanafusa and T. Miyamoto. *Proc Nat Acad Sci* 67(4):1797-1803, 1970.

A new virus was recovered from chick embryo cells containing a genetic factor "chick cell-associated helper factor" (chf). Although the chf could not mature into a complete virus by itself, it became transmissible after infection of C/O type chick embryo cells by avian leukosis virus or Rous sarcoma virus. The newly isolated virus was named RAV-60; it did not require the presence of another virus for its replication. RAV-60 grew in susceptible chick and quail cells; infected cells produced virus at a constant rate with minimal cytopathic effects. The host range of RAV-60 was the same as those of Rous sarcoma virus (RAV-60) and Rous sarcoma virus type $\beta(0)$; Japanese quail cells and Rous sarcoma virus type $\beta(0)$ -susceptible chick embryo cells were susceptible to the virus, and Rous sarcoma virus type $\beta(0)$ -resistant chick embryo cells were resistant to it. RAV-60 was antigenically identical to Rous sarcoma virus type $\beta(0)$ in the specificity and rate of inactivation by anti-Rous sarcoma virus type $\beta(0)$ antiserum. Rous sarcoma virus-RAV-60 had the type $\beta(0)$ specificity as Rous sarcoma virus type $\beta(0)$ in its sensitivity to interference induced by avian leukosis viruses. RAV-60 was structurally similar to Rous sarcoma virus type $\beta(0)$.

- 1087 ISOLATION OF A VARIANT STRAIN OF ROUS SARCOMA VIRUS ONCOGENIC FOR DUCKS AND MAMMALS. (E.) Kuwata, T. (Sch. Med. Chiba U., Japan) and H. Kawakami. *Arch Ges Virusforsch* 32(1):1-12, 1970.

The isolation of a strain of Rous sarcoma virus which proved to be oncogenic for ducks, mice and hamsters was described. The variant strain was developed from the Bryan standard strain (BS-RSV) which is not oncogenic for ducks or newborn mice. Cell suspensions of BS-RSV-induced chicken tumor were injected into ducklings which had been treated with cortisone; this method induced tumors in 4 ducklings, 3 of which regressed, but 1 grew to a large size (5.4 x 2.8 cm). Cells from this tumor were passaged further in ducks; metastases developed in the lung, spleen, liver and heart further confirming the oncogenicity of the BS-RSV variant (BK-RVS) for ducks; crude extracts were passaged for 30 generations without cortisone-treatment and continued to induce tumors in ducks. The oncogenic variant was passaged in ducks and injected into CFW mice, where it produced 1 tumor in 14 injected mice. In other passages in mice, BK-RSV induced tumors in 1/6 CFW mice and 2/8 AKR mice.

in experiments with hamsters, BK-RSV produced tumors in 2 of 6 injected animals. Neither mouse nor hamster tumors produced infectious RSV. However, sarcomas yielding infectious RSV were produced in the lungs of chickens injected with hamster tumor cells.

088 THE LOW MOLECULAR WEIGHT RNAs OF ROUS SARCOMA VIRUS: II. THE 7 S RNA. (E.) Bishop, T. M. (U. California Sch. Med., San Francisco), W. E. Levinson, D. Sullivan, L. Fanshier, N. Quintrell and Jackson. *Virology* 42(4):927-937, 1970.

The structure and chemistry of the 7S RNA of the Bryan and Schmidt-Ruppin strains of Rous sarcoma virus were investigated. The 7S RNA, which was purified by chromatography on columns of methylated albumin kieselguhr, appeared to be a single-stranded molecule with a molecular wt of 80,000. The nucleotide composition of the 7S RNA (which comprised 3-5% of the total viral RNA) was different in the 2 strains of virus, and was different from any known cellular RNA; an exceptionally high guanine plus cytosine content was found. This RNA was not appreciably methylated, suggesting that it is not a form of transfer RNA. Neither the 7S RNA nor the 4S transfer RNA were complementary to the Rous sarcoma virus genome, and no corresponding form of RNA could be identified in either normal or infected cells.

089 CHANGES IN DEOXYRIBONUCLEIC ACID SYNTHESIS REGULATION IN CHINESE HAMSTER CELLS INFECTED WITH SIMIAN VIRUS 40. (E.) Lehman, J. M. (U. Colorado Med. Sch., Denver) and V. Defendi. *J. Virol.* 6(6):738-749, 1970.

The patterns of cellular DNA synthesis in Chinese hamster cells after SV40 infection were studied to determine the relevance of cellular DNA induction to the phenomenon of cell transformation. No cell lysis was observed after SV40 infection but at a multiplicity of infection (MOI) of 50, 80-95% of the cells contained the virus-specific intranuclear antigen within 72 hr. In ³H-thymidine studies (0.2 µCi/ml) the infected cells had 85-90% labeled nuclei after 22-24 hr compared to the 50% of controls indicating that the SV40 infection stimulated DNA synthesis (only 2% of the newly synthesized DNA was viral DNA). Transformed cells were apparent in the infected cultures several weeks after infection and produced tumors (fibrosarcomas) at the injection site when injected into irradiated hamsters. The striking difference between infected and control cultures was a rapid increase in cells with 8n DNA content (from a steady 2% in controls to 4% at 6 hr, 18% at 36 hr, and 30-50% at 4 weeks in infected cells). The polyploid cells apparently resulted from an induction of 2 successive rounds of DNA synthesis in a G₁, S, or G₂ cell without an intervening mitosis.

090 SV40 THERMOSENSITIVE MUTANT: SYNTHESIS OF VIRAL DNA AND VIRUS-INDUCED PROTEINS AT NONPERMISSIVE TEMPERATURE. (E.) Takemoto, K. K. (Natl. Inst. Allerg. Infect. Dis., Natl. Inst. Hlth., Bethesda, Md.) and M. A. Martin. *Virology* 42(4):938-945, 1970.

The synthesis of viral DNA and virus-induced proteins at a nonpermissive temperature (40°C) was studied in the SV40 thermosensitive mutant (SV-L) grown in primary African green monkey kidney cells. Complement fixation and an indirect fluorescent antibody technique demonstrated that viral antigen and T-antigen were produced by infected cell extracts at similar titers at 37°C (128 and 64, resp.) and at 40°C (64 and 64, resp.), but the infectivity was higher at the lower temperature (1.5×10^9 compared to 5×10^5) plaque-forming units/ml. The physical properties (configuration, molecular size, polynucleotide sequence, and infectivity) of the viral DNA made at the nonpermissive and permissive temperatures were similar, although electron microscopy revealed fewer intranuclear virus particles in the cells infected at the higher temperature. SV-L virions formed at the permissive temperature were extremely thermolabile (0.001% survival after 60 min at 50°C) compared to the 100% survival of SV-S virions, the small-plaque mutant, indicating defects in the structural protein of SV-L.

1091 ALTERATION IN GANGLIOSIDE PATTERN AND SYNTHESIS IN SV40- AND POLYOMA VIRUS-TRANSFORMED MOUSE CELL LINES. (E.) Brady, R. O. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and P. T. Mora. *Biochem Biophys Acta* 218(2):308-319, 1970.

Changes in the ganglioside pattern of mouse cells caused by transformation by tumorigenic DNA viruses, including polyoma virus and SV40, were investigated. Ganglioside patterns of virally transformed cells were drastically altered compared to parent cell lines and spontaneously transformed cell lines. A reduction in the amount of the highest ganglioside homolog, *N*-acetylneuraminylgalactosyl-*N*-acetylgalactosaminyl-(*N*-acetylneuraminyl)-galactosylglucosylceramide (G_{D1a}), and an increase in *N*-acetylneuraminylgalactosylglucosylceramide (G_{Ma}), which becomes the principal ganglioside, were found. When strain AL/N mouse cells were transformed by DNA viruses, G_{D1a} and galactosyl-*N*-acetylgalactosaminyl-(*N*-acetylneuraminyl)-galactosylglucosylceramide (G_{M1}) were decreased from 1.8 and 1.5 nmoles/mg protein in normal cells to 0.14 and 0.08 nmoles/mg in polyoma virus-transformed cells, resp. When Swiss mouse cells were transformed by viruses, G_{D1a} and G_{M1} decreased, and hematoside (*N*-acetylneuraminylgalactosylglucosylceramide) (G_{M3}) became the principal ganglioside homolog, a result which was far more pronounced in cells cultured in Dulbecco-Vought medium than in cells cultured in Eagle's medium. Similar results were obtained by transforming BALB/c cells with either SV40 or polyoma virus. The dynamics of ganglioside reduction and increase in virally transformed cells were confirmed by incorporation studies with radioactive precursors. A common virus-regulated biochemical function appears to be present in SV40 and polyoma virus-transformed mouse cells, which is expressed in these changes in the membrane glycolipids of transformed cells.

1092 SUPERINFECTION OF SIMIAN VIRUS 40 TRANSFORMED PERMISSIVE CELLS WITH SIMIAN VIRUS

40. (E.) Barbanti-Brodano, G. (Inst. Microbiol., U. Bologna, Italy), P. Swetly and H. Koprowski. *J Virol* 6(5):644-651, 1970.

The capacity of a clone of African green monkey kidney cells previously transformed with SV40 to adsorb superinfectious doses of SV40 was investigated. Normally, SV40 permissive transformed cells adsorbed only negligible amounts of virus. When the transformed cells were incubated for 90 min with a homogenate of mouse embryo fibroblasts infected with polyoma virus, they adsorbed 20 times more virus than did untreated cells. Within 15 min after exposure to ^3H -labeled SV40 superinfection, treated cells had taken up 2.2% of the labeled virus; by 90 min postinfection, 4.5% of the virus had been adsorbed; thereafter, adsorption fell off slightly. Pretreatment of SV40-transformed cells with histones resulted in a 17-fold higher uptake of SV40 than was observed in untreated cells, and treatment with diethylaminoethyl dextran and a homogenate of noninfected mouse embryo fibroblast also enhanced the adsorption of SV40. Treatment of SV40-transformed cells with purified polyoma virus, receptor-destroying enzyme, neuraminidase, trypsin, heparin and dextran sulfate did not affect adsorption. Under conditions of enhanced viral adsorption, SV40 particles penetrated the nuclei of cells. The number of cells producing viral protein in superinfected transformed cultures was 15-fold greater than in untreated transformed cultures; the virus yield of SV40 superinfected transformed cells was 7 times less than the virus yield of African green monkey kidney cells 3 days after infection.

1093 SV40-TUMORIGENESIS IN MOUSE. (E.) Wesslen, T. (Inst. Med. Microbiol., U. Uppsala, Sweden). *Acta Path Microbiol Scand* 78(4):479-487, 1970.

The oncogenicity of SV40-transformed cells was investigated in mice after passage *in vitro* and *in vivo*. Virus-transformed cell lines were derived from kidneys and embryos of mice infected with SV40 at multiplicities of about 100 and tested for oncogenicity by injection into syngeneic mice (50×10^6 cells). Some mice receiving infected cells had been irradiated previously with 400 rads of whole-body X-irradiation. Infected kidney cells cultured for 1-6 months which were injected into mice produced small regressive tumors in a few cases, but otherwise were ineffective. When embryo cells infected with SV40 were injected into mice after 8 and 9 months in culture, walnut-sized regressive tumors appeared in irradiated mice, as well as a progressively growing tumor in 1 irradiated mouse. The mouse embryo cell line proved to be more actively oncogenic than the kidney cell line, the latter never producing tumors except for regressive ones in irradiated animals. After 4 *in vivo* passages, the SV40-containing tumor cells developed by an irradiated mouse were able to produce tumors in both irradiated and unirradiated mice. After multiple passages *in vivo*, the character of the tumor changed to an infiltratingly growing sarcoma metastasizing to regional lymph nodes. In repeated oncogenicity tests of *in vivo*-passaged

tumor cells, it was found that passaged cells produce tumors only in irradiated mice before they had undergone at least 2 passages, and thereafter produced tumors in all mice. At the third passage level 10^7 cells were required to produce tumors, while at the 22nd passage level, 10^4 cells produced tumors in 1 of 3 injected mice. The *in vitro* mouse embryo cells were cloned, as were cells from the 22nd *in vivo* passage; none of the cloned cells from the *in vitro* cells produced tumors, while clones from the *in vivo* passaged cells (10^3) produced tumors in most of the tests. All the cell lines contained SV40 until the 3rd wk after virus inoculation, after which SV40 could not be recovered from any line. Most tumor material did not contain SV40 specific complement-fixing antigen; the antigen titers of tumor cells which varied from 1:8-1:32 were not correlated to tumorigenicity. Animals carrying SV40 induced tumors had high titers of immunofluorescent antibodies for long periods of time to the SV40 neoantigen in their sera.

1094 THE SV PSEUDOVIRUS: ITS POTENTIAL FOR GENERAL TRANSDUCTION IN ANIMAL CELLS. (E.) Grady, L. (New York St. Dept. Hlth., Albany), D. Axelrod and D. Trilling. *Proc Nat Acad Sci* 67(4):1886-1893, 1970.

This report presents evidence that the SV40 pseudovirus is a potential general transducing virus based on measurements of reassociation rates and the finding that Vero cell DNA incorporated into pseudoviruses can be introduced into mouse embryo cells and penetrate the cell's nucleus without loss of physical integrity. Data demonstrate that DNA from pseudoviruses more closely resembles that of Vero cells than it does the DNA of mature SV40. Rates of reassociation of fast sequences of Vero cells and from pseudoviruses are similar with less than 1% nonspecific binding being observed in the initial sample; similarity in temperature stability of reassociated unique sequences indicated the precision of base pairing in Vero-pseudovirus hybrids to be similar to that of the reassociated, unique sequences of Vero DNA. Pseudoviruses entered the mouse embryo cell and in both stationary and dividing cultures approximately 10% penetrated the nuclei. Lysis of the nuclei and sedimentation yielded ^{32}P -DNA profiles identical to those of pseudovirus DNA even to the ratio of the amounts of 5S and 18S DNA. The SV40 pseudovirus and general transducing bacteriophage appear to be analogous in several respects.

1095 TRANSFORMATION OF HUMAN CELLS WITH DIFFERENT FORMS OF SV40 DNA. (E.) Aaronson, S. A. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and M. A. Martin. *Virology* 42(4):848-856, 1970.

The transformation of human fibroblast cells and the induction of T-antigen by the supercoiled DNAs (form I) of the small (SV-S) and large (SV-L) plaque variants of the tumor virus SV40 and by a mixture of open circular (form II) and linear forms of SV-S DNA were investigated. The whole SV-S

rus was 100 times more efficient than the SV-L virus in inducing T-antigen, but DNA I from both viruses exhibited similar induction levels (0.5-3% plateau levels with 0.4 μ g DNA I). The number of transformed colonies obtained with 0.4 μ g of DNA I is similar for SV-S and SV-L (0.06 and 0.1 colony/ 10^6 cells), and the cellular morphology of the colonies transformed with DNA closely resembled that observed with whole virus. Mixtures of the open circular and linear forms of SV-S DNA (0.05 μ g) were capable of inducing T-antigen (0.2%), transforming cells (20 transformants/ 10^6 cells), and yielded infectious progeny (1.1×10^5 plaque-forming units/ μ g DNA), but fragmented linear SV-S DNA (mechanically sheared in a French-type pressure cell) ranging in size from $3.0-8.6 \times 10^5$ daltons did not induce T-antigen or yield infectious virus.

96 TRANSFORMATION OF MOUSE MACROPHAGES BY SIMIAN VIRUS 40. (E.) Stone, L. B. Natl. Inst. Allergy, Infect. Dis., Natl. Inst. Health, Bethesda, Md.) and K. K. Takemoto. *J Virol* 5:621-627, 1970.

The ability of SV40 to transform mouse peritoneal macrophages was investigated. Macrophage cultures were infected by SV40 at a multiplicity of 10, and DNA synthesis and tumor antigen production were assayed to determine whether the normally non-dividing macrophage cells were proliferating. Tumor antigen was first seen at 24 hr after SV40 infection; by 72 hr the percentage of tumor-antigen positive cells had risen from 1% at 24 hr to 75%, and by 144 hr postinfection, 100% of the cells had tumor antigen. DNA synthesis was first observed 24 hr after infection, at which time the uptake of 3 H-thymidine into trichloroacetic acid-insoluble DNA at 1 hr was $10^{2.5}$ cpm. Seventy-two hr after infection, values for 3 H-thymidine uptake were $10^{3.75}$ cpm; after this point, DNA synthesis declined precipitously, thymidine uptake values returning to 10^2 cpm by 120-144 hr postinfection. During the tumor-antigen-producing period, it was possible to rescue SV40 from nondividing unaltered macrophages. About 66 days postinfection proliferating transformants appeared in the infected cultures. When these cells were cultured, they were found to be tumor antigen-positive and virus-negative. However, because of their morphological similarity to macrophages and their exhibition of phagocytosis, acid phosphatase, β_1 synthesis, and aminoacridine incorporation, these cells were thought to be transformed macrophages.

97 TRANSFORMATION OF RAT LYMPH NODE CELLS BY SIMIAN VIRUS 40: ATTEMPT TO "FIX" SPECIALIZED FUNCTION. (E.) Collins, J. J. (Massachusetts Gen. Hosp., Boston), K. J. Bloch and P. H. Black. *Nat Cancer Inst* 45(6):1097-1104, 1970.

In vitro production of a nonspecific antibody in response to oncogenic simian virus 40 (SV40) was attempted with suspension cultures of cells from pooled lymph nodes from rats hyperimmunized with phytohemagglutinin (PHA) and dinitrophenyl bovine serum albumin (DNP-BSA). At 40 hr after infection,

samples of cells revealed no SV40 T antigen either through inability of cells to support synthesis or undetectability by the indirect fluorescent antibody technique. At 34 days, few cultures showed lymphoblast transformation characterized by numerous prominent nucleoli and giant cells. Established cell lines upon fluorescent antibody staining revealed granular nuclear fluorescence characteristic of SV40 T antigen. Transformed cells grown in the presence of 14 C-leucine failed to incorporate labeled amino acid into the immunoglobulin molecules. Neither the transformed lines growing on glass nor untransformed lymphocytes in suspension at 5-7 wk after seeding appeared to synthesize rat immunoglobulin. Either infection of antibody producing cells did not occur or transformation was accompanied by a loss of specific function.

1098 RELATIONSHIP BETWEEN MOLECULAR LENGTH AND BIOLOGICAL ACTIVITY OF SV40 DNA. (E.) Yamamoto, S. (Okayama U. Med. Sch., Japan), S. Omura and T. Oda. *Acta Med Okayama* 24(3):273-285, 1970.

A correlation between the length of the DNA molecule in SV40 and the infectivity of the virus was observed. DNA was extracted from three separate groups of SV40: high-titered original virus, undiluted passaged original virus, and diluted passaged virus of the second group. Mean length of the DNA molecules in each group was, resp., 1.50 μ , 1.40 μ , and 1.47 μ . Undiluted passage of virus caused shortening of DNA and defective virus of low infectivity was produced; however, if the defective virus group received dilute passage again, infectivity was restored. Small circular DNA molecules shorter than 1 μ were observed in virions prepared from undiluted passages. Dimers and replicating forms of defective SV40 DNA were observed both in purified virion and in the nuclei of SV40 infected African green monkey kidney cells.

1099 EFFECT OF H-1 VIRUS INFECTION ON RNA SYNTHESIS IN NB CELLS. (E.) Fong, C. K. Y. (Putnam Mem. Hosp. Inst. Med. Res., Bennington, Vermont), H. W. Toolan and M. S. Hopkins. *Proc Soc Exp Biol Med* 135(3):585-588, 1970.

The effect of infection with H-1 strain virus on RNA synthesis in a cell line originally derived from SV40-transformed newborn human kidney cells (NB) was investigated. Monolayer cultures of NB cells were infected with H-1 at an input multiplicity of about 10-15, and RNA synthesis was assayed using cells labeled with 3 H-uridine. Cytopathic changes in the infected cells were first detected 24 hr after infection; at later stages, nuclear vacuolation, chromatin depletion, and disappearance of nucleoli were observed. The rate of RNA synthesis in infected cells rose sharply between 9-15 hr postinfection, and declined between 15-20 hr postinfection from 3.8 to 1.8 cpm of 3 H-uridine incorporated/ 10^5 cells/hr. From 15 hr postinfection, the rate of RNA synthesis in infected NB cells remained lower than that of uninfected cells (1.7 and 2.8 cpm 3 H-uridine/ 10^5 cells/hr at 20 hr postinfection; at 70 hr postinfection the rates were

0.3 and 1.7 cpm, resp.). The increase in uptake of uridine into RNA in H-1 virus-infected cells after infection was also observed in autoradiographic studies. After infection, the percentage of cells labeled with ³H-uridine in infected cultures declined from 100% at 8 hr to 23% at 48 hr. Uninfected cells continued to be labeled at about the 100% level till 48 hr postinfection. Gel electrophoresis showed that the 28S ribosomal RNA was selectively inhibited by viral infection, while stimulation was observed in the low molecular wt 4S RNA.

- 1100 VARIATION IN RESPONSE OF SYRIAN HAMSTER LUNG CELLS TO COMPLETE OR DEFECTIVE SV40 (PARA). (E.) Nachtigal, M. (Baylor Coll. Med., Houston, Texas) and J. S. Butel. *Proc Soc Exp Biol Med* 135 (3):727-731, 1970.

The cytopathic and antigenic responses of hamster lung fibroblasts to infection by intact or defective SV40 was investigated. Hamster lung cells in culture were infected with SV40 or with a defective strain of SV40 (PARA) in amounts of 20 plaque forming units (PFU)/cell of SV40 and 0.06 PFU/cell of PARA. No cytopathic effects were in evidence following infection of hamster fibroblasts with SV40; however, all cultures exposed to PARA exhibited transitory cytopathic effects. PARA- and SV40-transformed hamster fibroblast lines were tested by immunofluorescence for the presence of SV40 tumor and specific antigens, and for adenovirus tumor antigen. Six cell lines derived from cultures transformed by different clonal lines of PARA all contained SV40 tumor antigen. Cell lines transformed by SV40 exhibited no SV40 tumor antigen. All PARA-transformed cell lines contained SV40 specific antigen at the cell membrane, but specific antigen was not found in cells transformed by SV40.

- 1101 SIALIC ACID TRANSFERASES AND SIALIC ACID LEVELS IN NORMAL AND TRANSFORMED CELLS. (E.) Grimes, W.J. (Massachusetts Inst. Tech., Cambridge). *Biochemistry* 9(26):5083-5092, 1970.

The ability of particulate enzyme preparations from normal and SV40-transformed 3T3 Swiss and BALB/c mice cells to catalyze sialic acid transfer to glycoproteins was determined. Preparations from transformed 3T3 cells had only 55-60% of the sialyl transferase activity as normal cells, while preparations from spontaneously transformed cells had intermediate activity; transformed BALB/c cells had 31% as much sialyl transferase activity as normal cells. Incorporation of radioactivity into glycoproteins was stimulated 10% by 0.1% Triton-X. The optimal hydrogen ion concentration for the transferase was pH 6.5. The total sialic acid concentration/mg protein of the particulate cell fractions (which contained over 80% of the total cellular sialic acid) in transformed cells was 35% and 60% of that found in normal BALB/c and 3T3 cells, resp.

- 1102 CELL DENSITY-DEPENDENT CHANGES OF GLYCOLIPID CONCENTRATIONS IN FIBROBLASTS, AND LOSS OF THIS RESPONSE IN VIRUS-TRANSFORMED CELLS. (E.) Hakomori, S. (U. Washington Sch. Hlth. Commun. Med., Seattle). *Proc Nat Acad Sci* 67(4):1741-1747, 1970.

In the present investigation glycolipids of normal hamster kidney and human fibroblastic cultured cells at different stages of growth and with varying degrees of contact inhibition were analyzed and compared with the glycolipids of virally transformed cells. The concentration of galactosylgalactosylglucosyl-, N-acetylneuraminosylgalactosylglucosyl-, and N-acetylneuraminosyl-(N-acetylneuraminosyl)galactosylglucosyl-ceramide increased at high cell densities with decrease in concentration on successive passages or after malignant transformation of the cells. Glycolipids of human diploid fibroblasts showed a 1- to 2-fold increase with cell confluence and disappeared or were greatly reduced in concentration after transformation. Regulation of synthesis and degradation of carbohydrate chains showing density-dependent response, possibly through a contact-sensitive enzyme system, may be of crucial importance in understanding various phases of cell-sociologic phenomena, such as malignancy.

- 1103 SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID TRANSCRIPTION *IN VITRO*: BINDING AND TRANSCRIPTION PATTERNS WITH A MAMMALIAN RIBONUCLEIC ACID POLYMERASE. (E.) Herzberg, M. (Weizmann Inst. Sci., Rehovot, Israel) and E. Winocour. *J Virol* 6(5):667-676, 1970.

The *in vitro* binding pattern of mammalian RNA polymerase to simian virus 40 (SV40) DNA was studied by electron microscopy and velocity sedimentation techniques. An estimated 2.0 µg of RNA polymerase was required to saturate the binding sites in 0.1 µg of SV40 DNA. The majority of supercoiled SV40 DNA molecules revealed only a single binding site for mammalian RNA polymerase and a single chain of nascent RNA attached to the SV40 DNA template during transcription. The finding of a single binding site for RNA polymerase indicates that only part of the viral genome is transcribed *in vitro*.

- 1104 ELECTRON-MICROSCOPIC OBSERVATIONS OF POLYOMA VIRUS-TRANSFORMED MOUSE CELLS TREATED WITH SPECIFIC IMMUNE SERUM. (E.) Negroni, G. (Imperial Cancer Res. Fund., London, England) and R. Tilly. *J Cell Sci* 7(3):711-718, 1970.

Morphological changes in mouse cells transformed by polyoma virus and treated with virus-specific immune serum were observed by electron microscopy. Transformed nonmalignant cells were treated either with specific antiserum induced in mice by 6 i.p. inoculations of 10⁶ nonmalignant cells or with serum from untreated mice. In all experiments cells were also treated with complement. No morphological changes occurred in the cells treated with control serum and complement, while in cells treated with immune serum and complement, complete disruption of cells was observed. In another experiment in which mixtures of immune serum and complement were incubated with nonmalignant transformed cells for differing lengths of time, there were no morphological changes in nonmalignant transformed cells treated with control serum and complement, in nonmalignant transformed cells treated with immune serum only, and in normal mouse embryo cells treated with con-

rol (or immune) serum and complement. Changes in on-malignant transformed cells treated with immune serum and complement included discontinuity of cell membranes; the numbers of cells showing interruption of cell membranes increased with the duration of contact with complement and immune serum. Damaged cells showed a peripheral emptiness due to loss of organelles through the membrane lesions.

105 INHIBITION BY TOYOCAMYCIN OF RNA SYNTHESIS IN MAMMALIAN CELLS AND IN NORMAL AND AVIAN TUMOR VIRUS-INFECTED CHICK EMBRYO CELLS. (E.) Verak, L. (Duke U. Med. Ctr., Durham, N.C.), R. A. Conar, A. J. Langlois and J. W. Beard. *Biochem Biophys Acta* 224(2):441-450, 1970.

The effect of toyocamycin on RNA synthesis in mammalian cells and in normal and virus-infected chick embryo cells was investigated by density gradient centrifugation. Chick embryo cells and L cells were incubated with toyocamycin (0.1-2.0 µg/ml) for 20 min and labeled with ³H-uridine (chick embryo cells) or ¹⁴C-uridine (L cells). Without toyocamycin incorporation of radioactive uridine approached equilibrium with some radioactivity in the 45S region. Toyocamycin suppressed uridine incorporation into the 18S and 28S RNA in both cell species; in L cell RNA, but not in chick embryo RNA, there was a slight increase in radioactivity in the 45S region and a shift of 1 fraction of the radioactivity peak from the 28S to the 32S position. Increasing the dose of toyocamycin towards 2.0 µg/ml further suppressed L cell uridine uptake in the 45S region, and continued to suppress ribosomal RNA synthesis in chick embryo cells generally. The differences in the response of the 2 cell species to toyocamycin may reflect different enzyme sensitivities; the inhibitory effect of toyocamycin in chick cells may have been on both synthesis and conversion of the 45S precursor RNA. The nucleolar RNA formed in chick cells infected with MC29 virus was mainly ribosomal RNA precursor with no clear evidence of virus-specific RNA; this RNA was toyocamycin-resistant. Toyocamycin treatment caused nucleolar fragmentation and wide dispersion of nucleolar components in chick embryo cells, virus-infected chick cells and myeloblasts of BAI strain A virus leukemia.

106 FORMATION OF CELLULAR DEOXYRIBONUCLEIC ACID DURING PRODUCTIVE POLYOMA VIRUS INFECTION. (E.) Cheevers, W. P. (Cancer Res. Lab., J. Western Ontario, London, Canada), P. E. Branton and R. Sheinin. *J Virol* 6(5):573-582, 1970.

The formation of cellular DNA during productive polyoma infection at low input multiplicities (1-10 plaque-forming units/cell) in primary and secondary cultures of mouse embryo cells was studied using neutral and alkaline sucrose gradients. An increased rate of cellular DNA synthesis followed with ³H-thymidine (25,489 cpm compared to a control 21,609 cpm) was observed 15-18 hr after infection, but viral DNA synthesis was not detected until 3 hr later when 3% (898 cpm) of the total DNA synthesized was viral. After 27-30 hr, 86% of the DNA

synthesized was cellular and 14% was viral. DNA synthesized in polyoma-infected cells up to 18 hr after infection was of the same molecular size as the normal pre-infection DNA, but after 18 hr, the DNA consisted of 3 separate components: one component cosedimented with the normal cell DNA, another component sedimented as form I polyoma DNA, and the third component sedimented as a heterogeneous component consisting of discontinuous newly synthesized strands of cell DNA and arising by direct synthesis (not by degradation of the high molecular weight normal cell DNA) only after the initiation of viral DNA synthesis. The heterogeneously sedimenting component was then converted to normal cell DNA without prior degradation to acid-soluble components. The pattern of DNA synthesis is apparently altered late in the infection by a process associated with the replication of viral DNA.

1107 STUDIES ON THE IMMUNOCHEMICAL BASIS FOR ANTIGENIC VARIATION AMONG POLYOMA VIRUS STRAINS. (E.) Hare, J. D. (U. Rochester Sch. Med., N.Y.) and J. C. Chan. *J Nat Cancer Inst* 45(6):1179-1188, 1970.

Two serologically distinct plaque-sized variants of polyoma virus were examined by immunochemical analysis in order to determine the mechanism of their differing serological behavior. The cross-reactions of 2 polyoma virus strains, 210 and 3049, were determined by semiquantitative immunodiffusion with homologous and heterologous antisera. The 3049 preparation was 8 times more concentrated than the 210 preparation, and the titer of each virus strain was independent of the antiserum used to measure the antigen content. The antibody content of the anti-3049 antiserum was 4 times higher with homologous antigen than with heterologous antigen; with the anti-210 serum, the homologous antigen titer was about 8 times greater than the heterologous titer. In semiquantitative cross-absorption studies, dilutions of antisera were reacted with dilutions of homologous and heterologous antigen preparations, after which the ability of these absorbed antisera to form precipitin lines with the 2 antigens was tested in an agar diffusion system. When anti-3049 serum was absorbed with either 3049 or 210 preparations, antibody activity to both antigens was removed. Less 210 antigen than 3049 antigen was required to remove both anti-210 and anti-3049 activity. When the anti-210 serum was adsorbed with either virus, anti-3049 activity was removed by roughly equivalent amounts of either 3049 or 210 antigen. This finding appeared to suggest that anti-210 serum contained an antibody directed against an antigenic determinant represented on the 210 virus which was either hidden, absent, or significantly reduced in quantity in the 3049 virus population. The precipitin patterns which developed when anti-210 and anti-3049 sera reacted with 210 and 3049 antigen preparations indicated that the 3049 virus preparation contained a major antigenic determinant, "L", which was also present in the 210 virus. The 210 virus contained a major antigenic determinant, "S", which was un-

detectable in 3049 virus. However, hyperimmune anti-3049 rabbit serum did contain antibody to S, suggesting that this antigen is present in 3049 virus preparations, but in reduced quantities or sterically hidden. The S antigen did not cross-react with a small plaque variant of Toronto polyoma virus.

- 1108 DENSITY-DEPENDENT INHIBITION OF PROTEIN SYNTHESIS IN NORMAL AND VIRUS-TRANSFORMED CELLS. (E.) Waller, J. M. (Dept. Path., U. Chicago, Ill.) and W. H. Kirsten. *Virchow Arch Zellpath* 6(3):183-197, 1970.

Comparison of density-dependent inhibition between normal mouse cells and two cell lines transformed by polyoma and simian virus 40, and murine sarcoma virus was made by cocultivation, variations in serum concentrations, frequency of medium changes and cell overlays. The rate of protein synthesis increased initially 100-150% per day during logarithmic growth, reached a maximum, and then fell off to 0-10% at saturation density in the three cell lines with reduction occurring at a significantly lower cell density in the normal line. Growth characteristics of cocultivated cells were those of the transformed cells with protein synthesis decreasing only when cell population reached a relatively high cell density. Protein synthesis in normal cells treated by frequent washing and feeding was inhibited in a pattern characteristic of the virus-transformed cell lines with a 30% increase in final total protein content reached in frequently fed cell cultures when compared with cells fed every two days. When normal mouse cell culture was overlaid by 4.8×10^6 cells, protein synthesis was inhibited 49% by 12 hr after overlay; protein synthesis was inhibited only 20% when 20×10^6 transformed cells were overlaid on a homotypic cell culture. A difference in sensitivity to density inhibition of protein synthesis apparently exists between normal and transformed cells.

- 1109 TEMPERATURE-DEPENDENT PROPERTIES OF CELLS TRANSFORMED BY A THERMOSENSITIVE MUTANT OF POLYOMA VIRUS. (E.) Dulbecco, R. (Salk Inst. Biol. Stud., San Diego, Calif.) and W. Eckhardt. *Proc Nat Acad Sci* 67(4):1775-1781, 1970.

The effects of temperature-sensitive mutants of polyoma virus, ts-3 on the characteristics of BALB-3T3 cells transformed in tissue cultures were studied by the use of labeled thymidine and radioautography. There is some induction of cellular DNA synthesis in ts-3-infected cells at 39°C but the proportion of cells incorporating thymidine at 32°C is greater as is the induction of movement. Whereas topoinhibition is temperature-dependent for the ts-3-transformed cells, neither wound serum requirement nor growth in agar showed temperature-dependence. Possibly, temperature-dependent mechanisms can be controlled by the product of the ts-3 gene.

- 1110 THE EFFECT OF CYCLOHEXIMIDE ON DNA SYNTHESIS IN CELLS PRODUCTIVELY-INFECTED WITH POLYOMA VIRUS. (E.) Branton, P. E. (Ontario Cancer Inst., U. Toronto, Canada), W. P. Cheevers and R. Sheinin. *Virology* 42(4):979-992, 1970.

The pattern of DNA synthesis in mouse embryo cells productively infected with polyoma virus was studied with column chromatography and velocity sedimentation in the presence of cycloheximide (10 µg/ml). Cycloheximide reduced the synthesis of mature viral DNA to 3% of the control values and of cellular DNA to 22% of the control value with none of the aberrant cell DNA normally found late in polyoma infected cultures. The drug reversibly blocked the synthesis of mature 20S polyoma DNA, while viral DNA material sedimented heterogeneously at 16-20S on neutral sucrose gradients. Aberrant cell DNA synthesis may be linked to the ring closure (which is apparently the final step in the maturation process) of the circular DNA of polyoma virus.

- 1111 LACK OF INTERACTION BETWEEN POLYOMA VIRUS CAPSID AND MOUSE CELL DNA *IN VITRO*. (E.) Ho, J. K. (Indiana U. Med. Ctr., Indianapolis), G. Y. Chan and J. C. Chan. *Life Sci* 9(21):1255-1260, 1970.

The degree of interaction between polyoma virus (PV) capsid protein and DNA in mouse embryo fibroblasts was investigated. The empty capsid of PV was incubated with tritiated DNA from mouse embryo fibroblasts for varying periods of time, and the hemagglutinating activity of the PV and the presence of ^3H label in the precipitate of a PV-anti-PV serum reaction were examined. Incubation of PV and mouse embryo fibroblast DNA did not result in any significant reduction of hemagglutination titers of PV; an increase in the amount of DNA added to the reaction also did not reduce the hemagglutination titer. No significant amount of ^3H label was recovered from the reaction mixture containing DNA, PV and anti-PV serum. Apparently, no complex formation between PV capsid and mouse cell DNA occurred *in vitro*.

- 1112 EFFECTS OF ARGININE DEPRIVATION ON POLYOMA VIRUS INFECTION OF MOUSE EMBRYO CULTURES. (E.) Winters, A. L. (Sch. Med. U. Pennsylvania, Philadelphia) and R. A. Consigli. *J Gen Viro* 10(1):53-63, 1970.

The effects of arginine deprivation on polyoma virus activity in infected cultures of mouse embryo cells was investigated. Cultures were grown and maintained in Eagle's medium, from which amino acids were selectively withdrawn in the experiments. Polyoma virus synthesis appeared to depend on the presence of all the amino acids in the medium, but was most dependent on arginine, lysine and valine. Arginine deprivation inhibited viral synthesis to about 95%. Arginine deprivation also extended the eclipse period of the virus from 36-72 hr, and in-

hibited plaque-forming activity and hemagglutinating activity during the eclipse period. Plaque-forming activity was inhibited by as much as 90% by arginine deprivation; at 50 hr after infection, log PFU/ml of hemagglutination units in arginine-depleted cells were recorded as 9, while values for complete medium viruses were 30. Polyoma virus DNA synthesis was decreased by 60% by arginine deprivation; however, arginine deficiency did not effect the number of cells synthesizing antigens. Virus synthesis recovered within 7 hr after the addition of arginine to the depleted medium, suggesting that arginine deprivation may have inhibited a late step in virus synthesis. The encapsidation of viral DNA in arginine-depleted cultures was inhibited by about 10%.

- 1113 POTENTIATION OF VIRAL CARCINOGENESIS BY IMMUNOSUPPRESSION. (E.) Allison, A. C. Clin. Res. Cntr., Northwick Park, Harrow, Middlesex, U.K.). *Brit Med J* 4(5732):419-420, 1970.

The effect of immunosuppression on tumor development in mice infected with polyoma virus was investigated. It was observed that inoculation of newborn mice with virus produced a high incidence of tumors, whereas inoculation of adult mice seldom produced tumors. To test the hypothesis that the low inducibility of tumors in adult mice was a result of increased immunocompetence in adults, mice were thymectomized, infected with polyoma virus, and given weekly injections of antilymphocyte serum. When tumors began to appear, some mice were given adult lymphoid cells to restore immunocompetence, and others were given lymphoid cells already sensitized against the antigens of the polyoma virus-induced tumor. No tumors developed in this last group, while the other experimental group and controls which had been thymectomized and infected but which had not received restorative doses of lymphoid cells developed tumors in nearly 100% of cases. These findings suggested that adult mice were protected because they were able to mount an effective immune response against polyoma virus-induced tumors. In another experiment, adult and newborn mice were inoculated with polyoma virus. Ten days and 6 wk later their lymphoid cells were tested for sensitization to the virus by transferring lymphoid cells from these mice to mice which had been inoculated with polyoma virus. Lymphoid cells from the adult mice prevented tumor development in recipient mice. Lymphoid cells from newborns prevented tumor development when taken 6 wk after inoculation with virus; they did not prevent tumor development when taken 10 days after inoculation. Apparently, cell-mediated immunity develops slowly in newborns, and is therefore unable to check tumor development.

- 1114 GLYCOPROTEIN SYNTHESIS AND DEGRADATION: GLYCOPROTEIN:N-ACETYL GLUCOSAMINE TRANSFERASE, PROTEOLYTIC AND GLYCOSIDASE ACTIVITY IN NORMAL AND POLYOMA VIRUS TRANSFORMED BHK CELLS. (E.) Bosmann, H. B. (U. Rochester Sch. Med. Dent., N. Y.) and G. Z. Pike. *Life Sci* 9(24):1433-1440, 1970.

Glycoprotein synthesis and degradation in virus-transformed hamster kidney cells was investigated. Normal hamster kidney cells and hamster kidney cells transformed by polyoma virus were grown in monolayer cultures for assay of glycoprotein-related enzymes. In normal cells, enzymes could be found in 3 groups: those with no activity or less than 20 nmole/hr/mg protein, those with more than 20 nmole/hr/mg but less than 150 nmole/hr/mg, and those with more than 150 nmole/hr/mg. In normal cells, enzymes in the first group included α -D-glucosidase, β -D-glucosidase and α -L-fucosidase; enzymes in the second group included N-acetyl-D-galactosaminidase and acid phosphatase; enzymes in the third group included α -D-galactosidase and N-acetyl- β -D-glucosaminidase. In each instance except β -D-glucuronidase, the polyoma virus-transformed cells had higher levels of enzyme activity than the normal cells. α - and β -D-Glucosidase and β -D-xylosidase had no activity in normal cells, but had measurable activity in virus-transformed cells. Virus-transformed cells had about 1.9 times the proteolytic activity of normal cells; the transfer of N-acetylglucosamine onto glycoprotein acceptors (endogenous or exogenous) was markedly increased in virus-transformed cells. Apparently, the abnormal N-acetyl glucosamine residues found in polyoma virus-transformed hamster kidney cells may be a result of either or all of the following factors: increased proteolytic activity, increased glycosidase activity or increased transfer of N-acetylglucosamine onto glycoprotein on the cell surface.

- 1115 PLAQUE ASSAY TECHNIQUES FOR MURINE LEUKEMIA VIRUSES. (E.) Rowe, W. P. (Natl. Inst. Allerg. Infect. Dis., Bethesda, Md.), W. E. Pugh and J. W. Hartley. *Virology* 42(4):1136-1139, 1970.

- 1116 IMMUNOSUPPRESSIVE EFFECT OF SURGERY. (E.) Park, S. K. (Grad. Hosp. U. Pennsylvania, Philadelphia), J. I. Brody, H. A. Wallace and W. S. Blakemore. *Lancet* 1(7689):53-55, 1970.

The comparative immune reactivity of peripheral blood lymphocytes obtained from surgical patients was investigated to determine the effect of surgical procedures on immunological competence. DNA synthesis, as measured by the incorporation of ^{14}C -thymidine under phytohemagglutinin stimulation, was assayed in lymphocytes grown in cell culture in autologous plasma, in normal lymphocytes from surgical patients grown in plasma from unoperated normal patients. Surgical procedures performed on the test patients included cholecystectomy, cardiac valve replacement, esophagectomy for esophageal carcinoma, abdominoperineal resection and hysterectomy. All patients exhibited depressed immunological competence following surgery, as evidenced by a diminished ability to incorporate radioactive thymidine. Immunological depression was most severe in patients undergoing cardiac surgery for aortic insufficiency, and in patients undergoing pneumonectomy and esophagectomy for carcinoma. In the carcinoma patients, post-operative values for ^{14}C -thymidine uptake were 0.6% and 1.2% of preoperative levels for pneumonectomized and esophagectomized patients, resp., 2 hr post-operatively. While patients undergoing other operations recovered immunological competence by 7 days after their operations, these patients' thymidine incorporation at 7 and 6 days post-operatively were only 19 and 36% of normal, resp. The acceleration of metastasis which often occurs post-operatively in carcinoma patients may be explained by the suppression of immunocompetence associated with the surgical ordeal.

- 1117 TUMOUR DEVELOPMENT FOLLOWING IMMUNOSUPPRESSION. (E.) Allison, A. C. (Natl. Inst. Med. Res., London, England). *Proc Roy Soc Med* 63(10):1077-1080, 1970.

The effect of restoration of immunity on viral induction of tumors was investigated in mice. Female mice were thymectomized and maintained on injections of rabbit anti-lymphocytic globulin for 10 days, at which time they were given i.p. injections of 10^5 TCID₅₀ polyoma virus. Subsequently, some of the mice were given spleen cells from normal mice, and some were given spleen cells from polyoma virus-infected mice (10^6 cells/g wt of recipient) to restore tumor immunity. Eight wk later, all of the unrestored mice, and all but 1 of the mice restored with normal spleen cells had developed tumors: tumors were mammary adenocarcinomas in all but 2 cases. None of the mice given polyoma virus-sensitized spleen cells developed tumors. In a related experiment, 18 mice with small mammary tumors had their tumors excised; mice were then given 5×10^5 polyoma-sensitized syngeneic spleen cells, and the remaining 9 were left untreated. All mice in the untreated group developed tumors, while only 1 of the mice given virus-sensitized spleen cells developed tumors. These results appear to demonstrate that the main factor allowing polyoma virus oncogenesis in thymectomized rats is suppression of cell-mediated immunity.

- 1118 MALIGNANT TUMORS FOLLOWING IMMUNOSUPPRESSIVE THERAPY. (E.) Pritzker, K. P. H. (Path. Inst., McGill U., Montreal, Quebec, Canada), S. N. Huang and K. G. Marshall. *Canad Med Ass J* 103(13):1362-1365, 1970.

Malignant disease associated with renal transplantation and immunotherapy was observed in 2 cases. In 1 case, a 27-yr-old Chinese male received a kidney transplant 4 yr before his death; immunosuppressive therapy (prednisone and azathioprine) was administered intermittently throughout the course of the patient's observation. Autopsy revealed a leiomyosarcoma of the bowel metastatic to the liver. In the other case, a 38-yr-old female received a kidney transplant and immunosuppressive therapy (antilymphocyte serum, prednisone and azathioprine). Six months after the transplantation, carcinoma *in situ* of the cervix uteri was diagnosed. It was thought that a causal connection between immunosuppressive therapy and cancer was probable in the first case and circumstantial in the second. The incidence of neoplasms in immunologically suppressed patients is evidently higher than in other groups, and it appears that immunosuppressive therapy sufficient to allow survival of an allogenic graft may well be sufficient to allow development of spontaneous tumors which are less antigenic than grafts.

- 1119 ANTIBODY-PRODUCING CAPACITY IN HUMAN CANCER. (E.) Lee, A. K. Y. (Walter Eliza Hall Inst. Med. Res., Victoria, Australia), M. Rowley and I. R. Mackay. *Brit J Cancer* 24(3):454-463, 1970.

The ability to produce antibodies to flagellin from *Salmonella adelaide* was tested in 61 patients with cancer and 2 sets of matched controls, one of hospital patients with non-malignant diseases and one of healthy patients. Of 61 subjects, 27 were designated "active" cancer cases, having non-lymphomatous malignancies; 34 patients in the "cured" group had been successfully treated for malignant disease with surgery and/or radiotherapy. All subjects were given s.c. injections of 5 mg of flagellin. Natural antibody to flagellin (IgM class) was found in 84% of active cancer patients, in 93% of cured patients, and in 96% of controls. In active cancer patients, the mean peak titer for total antibody 2 wk after injection of flagellin was 342, compared to a mean peak titer of 1002 for hospital controls. Ten wk after injection with flagellin, IgG antibody titers in controls were at 1.5 (log₁₀ titer) for controls and 0.5 for cancer patients. In 13 cancer patients who survived for more than 6 months after injection of flagellin, the mean peak titer for total antibody was 420, compared to titers of 820 for hospital controls; IgG antibody titers for these 2 groups were 8 and 86, resp. For 14 patients who survived less than 6 months after injection, mean peak titers for total and IgG antibody were 276 and 15, resp., compared with total antibody and IgG titers of 1190 and 57, resp., for hospital controls. Antibody-producing capacity for patients regarded as "cured" by surgery and/or radiotherapy was significantly greater than it was in hospital controls, but significantly less than in healthy controls. The findings may be explained

by an immunodepressive effect specific for cancer or associated with general debility, or by the occurrence of cancer preferentially in those with impaired immunocompetence.

- 1120 ANTIGENIC CHARACTERS IN SPONTANEOUS CELL CARCINOGENESIS. (E.) Vernekar, S. D. (Cancer Res. Inst., Tata Mem. Ctr., Parel, Bombay), S. G. Gangal and K. J. Ranadive. *Indian J Exp Biol* 8(1):11-14, 1970.

The antigenicity of a line of mouse fibroblast cells which exhibited spontaneous transformation (line C3HFB₁) was investigated. For antigenic analysis, the cell line was divided into 4 phases: primary cultures of fibroblasts in the second passage; non-malignant cells up to passage 40 showing morphological transformation; transformed, malignant cells at the 50th passage; and fresh trypsinized embryonal cells (controls). Tanned red cell agglutination and complement fixation tests were used for studying the antigenic constitution of cells. Antisera were prepared in rabbits against all 4 different cell types. The cells appeared to lose some embryonal antigens during the early stages of cultivation. Transformed, nonmalignant cells showed the presence of modified antigens after 20 passages, and the malignant cells at passage 50 showed antigenic similarities to the embryonal cells. The antigenic similarity of malignant and embryonal cells suggest that continuous stimulation to growth and transformation *in vitro* may have hastened the process of antigenic derepression.

- 1121 HUMAN THYMUS-LYMPHOID TISSUE ANTIGEN AND ITS PRESENCE IN LEUKAEMIA AND LYMPHOMA. (E.) Yata, J. (Karolinska Inst., Stockholm, Sweden), G. Klein, N. Kobayashi, T. Furukawa and M. Tanagisawa. *Clin Exp Immunol* 7(6):781-792, 1970.

An antigen associated with leukemias, lymphomas and various lymphoid tissues was demonstrated by immunodiffusion tests with tissue homogenates using an antiserum prepared by immunizing rabbits with human leukemic tissue homogenate following preliminary induction of tolerance to normal peripheral leucocytes by repeated injections. In gel diffusion precipitation tests, positive reactions to the putative antigen were found for all undifferentiated leukemic cells and all myeloblastic leukemia cells. Positive reactions were also found for 67% of malignant lymphoma cells tested, for Burkitt's lymphoma, for postnasal space carcinoma, for thymoma, and for papilloma of the vocal cords. Thymus homogenates from patients dead of nonmalignant diseases also gave positive reactions, as did the spleen and lymph nodes. There was no antigen reaction for extracts of normal non-lymphoid tissue. The antigen could be demonstrated in fetal thymus at 3 months of gestation. In spleen and lymph nodes, the antigen appeared later and less constantly than in the thymus. The antigen was located in the cytoplasm of nearly 100% of thymocytes, about 30% of spleen cells, and 30% of peripheral lymphocytes by the fluorescent antibody method. No antigen could be

demonstrated in bone marrow, brain, thyroid, liver or kidney cells.

- 1122 CHANGES IN THE LYMPHOID SYSTEM FOLLOWING THE INTRAVENOUS INJECTION OF PHYTOHEMAGGLUTININ IN MICE: A PILOT STUDY. (E.) Hartveit, F. (Dept. Path., U. Bergen, Norway). *Acta Path Microbiol Scand* 78(5):525-531, 1970.

The effects of i.v. injection of phytohemagglutinin (PHA) on lymph nodes, spleen and thymus were investigated in male mice. PHA was injected in a saline solution at a concentration of 1.7 mg/ml (approximately 68 mg/kg body wt). Twenty-four hr after injection, lymph nodes were enlarged, soft and microscopically edematous, with marked proliferation of the follicles. Pyroninophilic cells were seen in the germinal centers, paracortically and in the medullary cords. Mast cells in the sinuses were in the process of degranulation. By 6 days post-injection, extra-medullary hematopoiesis was present to a minor degree in most nodes, and some germinal areas showed necrosis. After 11 days, swollen medullary cords had shrunk somewhat, and cellular recovery was evident. Spleen wt of PHA-treated animals increased nearly 2-fold (121 mg in treated animals, 71 mg in normals), and scattered groups of cells appeared which were intensely pyroninophilic. By 2 days post-injection, follicles were markedly enlarged; however, recovery seemed complete by day 11. Few changes were noticed in the thymus of PHA-treated animals; however, the cortex showed active proliferation with large pale pyroninophilic cells. The regular proliferation noted in the lymph nodes may have been due to stimulation of the lymphoid cells *in situ*, while the larger grossly irregular proliferation found in particular lymph nodes may have been caused by secondary stimulation of this altered cell population by PHA-stimulated cells from the thymus.

- 1123 LYMPHORETICULAR MALIGNANCIES AND IMMUNOLOGIC ABNORMALITIES IN A SIBSHIP. (E.) Potolsky, A. I. (332 Oxford Ave., Palo Alto, Cal.), C. W. Heath, C. E. Buckley III, and D. T. Rowlands, Jr. *Amer J Med* 50(1):42-48, 1970.

Immunological studies were performed on 4 sibs surviving from an original sibship of 12 individuals, 5 of whom had died of lymphoreticular malignancies, and 3 of other causes. Of the 5 dying of lymphoreticular malignancies, 2 had chronic lymphocytic leukemia, 1 had lymphocytic lymphoma, 1 had acute leukemia, and 1 had reticulum cell sarcoma. In 1 of the 4 surviving sibs, a 68-yr-old woman, moderately enlarged lymph nodes were observed in the neck, and biopsy revealed changes consistent with lymphosarcoma. All 4 sibs showed clear abnormalities in immunologic tests. Each had decreased immunoglobulin (IgG) levels, and each showed depression in delayed hypersensitivity skin test responses. One individual showed an increased level of immunoglobulin IgM, a decreased level of anti-B isoagglutinin (1:16), and a slight increase in alpha₂-globulin. The patient with signs of lymphosarcoma showed de-

creased levels of IgA and IgM, a slight decrease in gamma globulin and total protein, decreased lymphocyte responsiveness to phytohemagglutinin, an increased number of lymphocytes in bone marrow, and an absence of lymph node germinal centers. All sibs had normal chromosome numbers and karyotypes, with no evidence of increased chromosomal breakage. No evidence of virus was found in any of the sibs. The findings suggest a genetic relationship between immunologic abnormalities and susceptibility to lymphoid neoplasia.

- 1124 HYBRID CELL LINE FROM A CLONED IMMUNOGLOBULIN-PRODUCING MOUSE MYELOMA AND A NON-PRODUCING MOUSE LYMPHOMA. (E.) Mohit, B. (Clin. Ctr. Natl. Inst. Hlth., Bethesda, Md.) and K. Fan. *Science* 171(3966):75-77, 1971.

Hybrid cells were produced by fusing cloned mouse myeloma cells which produced immunoglobulin and cells of a mouse lymphoma originally induced by 7,12-dimethylbenz(a)anthracene which did not produce immunoglobulin. The myeloma was resistant to 8-azaguanine, and produced γ G and free kappa chain immunoglobulins; the lymphoma was resistant to bromodeoxyuridine. Fusion of the parent cell lines was effected with 10^7 cells of each parent line and 2000 hemagglutination U of Sendai virus inactivated by β -propiolactone. After 2 wk in culture, the hybrid cells showed many fused giant cells, and after 6 wk, hybrid cells began to divide and increase in number. The hybrid cells generally had the sum of the chromosome numbers of the respective parent lines. Although no synthesis of α G heavy chain proteins was observed in the hybrid cells, they contained the membrane antigens of both parents, and synthesized free kappa chain proteins. The lack of heavy chain protein synthesis in hybrid cells may have been due to interference with its synthesis during either transcription or translation, possibly by means of a repressor or other control molecules contributed by the non-immunoglobulin-producing parent cell line.

- 1125 THE ROLE OF THE REGIONAL LYMPH NODES IN THE DEVELOPMENT OF HOST IMMUNOLOGICAL RESPONSE TO TUMORS. (E.) Pilch, Y. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), D. S. Bard and K. P. Ramming. *Amer J Roentgen* 111(1):48-55, 1971.

The role played in host resistance to tumors by regional lymphatics and lymph nodes was investigated. Normal and tumor-bearing mice (which had been injected with fibrosarcoma cells) were given combinations of the following treatments: right regional lymphadenectomy, sham lymphadenectomy, amputation of the tumor-bearing limb. The size and incidence of tumors developing in these groups was observed. Practically no difference in mean tumor volumes, tumor incidence, or mortality between any of the treatment groups was found, suggesting that removal of regional lymph nodes does not interfere with the host's response to a primary tumor transplant. Removal of regional lymph nodes does not seem to affect the host's ability to resist further tumor growth.

- 1126 IMMUNOLOGIC CROSS-REACTION BETWEEN HUMAN LEUKEMIC PLASMA AND AVIAN LEUKOSIS GROUP-SPECIFIC ANTISERUM. (E.) Cohen, S. (Wayne St. U. Sch. Med., Detroit, Mich.), L. M. Weiner, C. A. Baechler and C. S. Stulberg. *Proc Soc Exp Biol Med* 135(3):800-803, 1970.

Plasma from a patient with acute monomyelogenous leukemia was subjected to immunodiffusion tests with antiserum prepared from a hamster bearing fibrosarcomas induced by Rous sarcoma virus. Plasma from the patient gave at least 2 precipitin bands with the hamster serum. One of the bands merged in a reaction of identity with precipitin bands formed by avian leukosis virus. The leukemia patient's plasma also contained virus-like particles measuring 46-56 nm and were not seen in any of the normal plasmas studied. The particles estimated to be concentrated in amounts of 5×10^7 /ml of plasma; 20% of the particles were in the doughnut form. The reaction of the leukemia plasma with the hamster antiserum apparently represented a genuine cross-reaction between antigens from a human leukemic source and antibodies directed against the avian leukosis group-specific antigen.

- 1127 SHARING OF INDIVIDUAL ANTIGENIC DETERMINANTS BETWEEN A γ G AND A γ M PROTEIN IN THE SAME MYELOMA SERUM. (E.) Penn, G. M. (Rockefeller U., New York, N. Y.), H. G. Kunkel and H. M. Grey. *Proc Soc Exp Biol Med* 135(3):660-665, 1970.

An attempt was made to isolate two lambda proteins from the same human myeloma serum and to determine the nature of antigenic specificity through plasma-phoresis and immunoelectrophoresis. Two proteins, one a γ M and the other a γ G3, were isolated and were shown to have only lambda light chains. They were also shown to share individual antigenic specificity with localization pointing to the light chains and the variable regions of the heavy chains. This sharing strongly suggests that a segment or the entire variable region of the two proteins are markedly similar.

- 1128 IgM DYSPROTEINEMIA AND ACUTE MYELOMA. (PLASMOCYTIC RETICULOSARCOMA OF THE BESSIS AND SCEBAT TYPE.) (It.) Pratesi, G. (Hosp. San Giovanni, Rome, Italy), A. Alfieri, L. Barbatano and A. Fremiotti. *Recent Progr Med* 49(3):xxi-xxxviii, 1970.

A case of acute myeloma with hepatosplenomegaly and an IgM and IgG dysproteinemia in a 64-yr-old woman is presented. The heavily prevalent IgM fraction constituted 33% of the total serum proteins. The cytology of the bone marrow (sternal puncture) revealed a plasmocytic reticulosaoma with atypical plasmocytic elements with giant nuclei or double nuclei with enlarged nucleoli and decreased cytoplasmic contents. The peripheral blood revealed large flattened cells and reticular elements indicating a tendency towards the plasmocytic development. The ambiguous origin of the IgM and IgG producing cells is analyzed in terms of the possibility that a single cell could produce under certain conditions two types of immunoglobulins.

he described case seems to confirm that no precise relationship between the morphology of a proliferating cell and the production of a specific type of immunoglobulin exists.

- 29 EVIDENCE FOR ANTIGENICITY IN HUMAN TUMOURS WITH REFERENCE TO BOTH MELANOMA AND ACUTE LEUKEMIA. (E.) Fairley, G. H. (St. Bartholomew's Hosp., London, England). *Brit Med J* 4(5733):483-34, 1970.

Antigenicity in human tumors was investigated in patients with melanoma and leukemia. It was shown that 86% of the patients with localized melanoma (i.e., patients in whom the disease was confined to the primary anatomical site or to the primary site and the regional lymph nodes) had autoantibodies to melanoma, while only 11% of patients with disseminated disease had antibodies. Antibodies disappeared in 3 melanoma patients when the disease became widespread. However, patients with generalized melanoma produced antibodies when injected with more than 300×10^6 radiation-inactivated tumor cells. While the antibodies may have little effect on massive tumors, they may inhibit metastases. The evidence that there exists a host immune resistance to acute leukemia includes the fact that there are on record 103 cases of people with the disease who are alive and symptom-free 5-17 yr after the onset of symptoms. It was found that leukemic blast cells stimulate autologous lymphocytes, and that tumor-associated antigens exist on the cell surface. Antigenic response to leukemic cells was greater after immunization with autologous irradiated blast cells.

- 30 RELATION BETWEEN BREAST CANCER AND S BLOOD-ANTIGEN SYSTEM. (E.) Boston Collaborative Cancer Surveillance Program, Tufts U. *Lancet* 1(7694):301-304, 1970.

A association was discovered between the phenotype in the S antigen system and breast cancer; the populations examined were breast cancer patients in hospitals in the Boston area. There were 82 breast cancer patients in 1 hospital group and 89 breast cancer patients in the other. Control groups were comprised of patients with cancer in sites other than the breast. In 1 group the proportion of the ss phenotype among breast cancer patients was 61%, while among controls it was 46%. In the other group, 56% of breast cancer patients had the ss phenotype and 41% of controls had the ss phenotype. The point estimate of relative risk for breast cancer in the presence of ss phenotype was 1.8, with 95% confidence limits of 1.2 and 2.7. In addition, the association between ss phenotype and breast cancer was more prominent among patients whose disease had been diagnosed before the age of 50 yr. Despite the excess of ss phenotype among breast cancer patients, there appeared to be a deficit of the phenotype NN in the breast cancer patients relative to controls.

- 31 TUMOR SPECIFIC T-LIKE ANTIGEN OF HUMAN BREAST CARCINOMA. (E.) Taylor, G. (Roy. Infirmary, Manchester, England) and J. L. Odili. *Brit J Cancer* 24(3):447-453, 1970.

An autoimmune response to a neoantigen prepared by fractionation of mammary adenocarcinoma tissue was observed in the serum of 1 patient; in sera of 10 other mammary cancer patients tested no autoantibody response was observed. The antibody response was directed only against the nuclear fraction of the tumor homogenate; there was no response to normal breast tissue in the same individual. When the autoantibody reacting serum was tested against the nuclear fraction of the other 10 mammary adenocarcinomas, tumors from 6 subjects gave positive reactions. That this reaction was specific for mammary adenocarcinoma was demonstrated by the finding that serum prepared from nuclear fractions of adenocarcinomas derived from stomach, rectum, colon, and esophagus all gave negative results when tested against the antibody-containing serum. The nuclear fractions of the 7 mammary adenocarcinomas which apparently shared a common neoantigen were incubated with DNase and RNase, and 6 of the neoantigen were found to be resistant to RNase and were destroyed by DNase; the other neoantigen was inactivated by RNase. The neoantigens appeared to be heat-labile at 37° in pH 7.4 buffer and lost the ability to fix complement after 3-4 hr of incubation under these conditions. Cross absorption also indicated that 2 antigens were present in the sera of the patient with the autoimmune response.

- 1132 DETECTION AND ISOLATION OF TUMOUR-SPECIFIC ANTIGEN ASSOCIATED WITH A SPONTANEOUSLY ARISING RAT MAMMARY CARCINOMA. (E.) Baldwin, R. W. (Cancer Campaign Res. Lab., U. Nottingham, England) and M. J. Embleton. *Int J Cancer* 6(3):373-382, 1970.

Membrane immunofluorescence tests detected a tumor-specific antigen on the surface of a spontaneously arising rat mammary carcinoma. Antisera to the tumor cell lines were prepared in syngeneic rats treated with irradiated (15,000 rads) tumor grafts or with excision of an s.c. tumor mass. Using this antiserum, antigenic reactions were found in 1 of 8 rat carcinomas by membrane immunofluorescence. Fluorescence indices for this antigenic tumor (designated Sp4) had a mean value of 0.36 ± 0.03 . Tumor antigens on Sp4 were individually distinct, and there was no evidence for major common antigens shared by Sp4 and other mammary carcinomas. The capacity of subcellular fractions of Sp4 tumor to absorb anti-Sp4 antibodies was tested. Antibody absorption with amounts of tumor membrane fractions equalling 10-22.5 mg of protein/ml reduced the fluorescence index of anti-Sp4 antiserum to the limiting value for a significant reaction. Absorption of antiserum with Sp4 soluble fraction (91 mg protein/ml) produced no significant loss of anti-Sp4 antibody; membrane fractions of Sp4 absorbed almost all antibodies from an alloantiserum, however. Plasma membrane fractions of Sp4 failed to induce tumor rejection responses when injected into syngeneic rats (100% of rats developed tumors). Sp4 plasma membrane fractions did produce a weak humoral antibody response, however. A weak but consistent humoral antibody response was obtained in rats injected with irradiated tumor grafts.

- 1133 TUMOR-ASSOCIATED IMMUNOGLOBULINS: THE ELUTION OF IgG2 FROM MOUSE TUMORS. (E.)

Ran, M. (Dept. Microbiol., Tel Aviv U., Israel) and I. P. Witz. *Int J Cancer* 6(3):361-372, 1970.

The amount of immunoglobulin IgG2 found in eluates of tissue preparations of primary and transplanted mouse tumors was analyzed semi-quantitatively. Tumors were fibrosarcomas induced in mice by s.c. or i.m. injections of 0.2 ml benzo(a)pyrene. Low amounts of IgG2 were found in eluates of sediments from low-speed centrifugation of cells. Only 0-6% of the total IgG2 units eluted from all sub-cellular fractions of tumor cells was eluted from low-speed sediments. Medium-speed sediments yielded higher IgG2 contents (14-31% of total IgG2). Membrane-rich, high-speed sediments were invariably richest in elutable IgG2, yielding up to 78% of total IgG2. Relatively large amounts of IgG2 could also be eluted from the high speed sediments of spontaneous mouse mammary tumors, indicating that the immunoglobulin is associated with the surface of the tumor cells. No IgG2 could be eluted from high speed sediments of normal muscle cells; however, IgG2 could be eluted from normal liver cells. IgG2 was elutable in much lower amounts from high speed sediments of transplantable benzo(a)pyrene-induced sarcoma cells than from primary sarcomas. IgG2 appears to be preferentially bound to tumor cells and is not a random contaminant of the cells or of the membrane-rich subcellular fraction.

1134 THE *IN VIVO* SPLEEN RESPONSE TO SHEEP ERYTHROCYTES IN BURSECTOMIZED-IRRADIATED CHICKENS. (E.) Alm, G. V. (Variety Club Res. Ctr., La Rabida-U. Chicago Inst., Ill.). *Acta Path Microbiol Scand* 78(5):641-646, 1970.

The *in vivo* response of the chicken spleen to immunization with sheep erythrocytes was studied in 8-wk-old chicks having undergone bursectomy and/or X-irradiation (600 rads). Sheep erythrocytes were given by injection to selected birds in amounts of 5×10^9 cells/kg body wt. Immunization of irradiated birds increased their spleen wt, while no such increase was observed in irradiated and bursectomized birds. Incorporation of ^3H -thymidine by immunized and irradiated chickens was higher than incorporation by immunized and bursectomized birds (incorporation of ^3H -thymidine expressed as cpm/ 10^6 spleen cells was, resp., 48.16 and 27.91 for the 2 test groups). Plaque-forming cell responses in variously treated chickens were assayed in spleens. Spleens of immunized and irradiated chickens contained more plaque-forming cells than did spleens of immunized, irradiated and bursectomized chickens. The former group showed 548 plaque-forming cells/ 10^6 spleen cells assayed by a direct technique; the latter group showed 25-67 plaque-forming cells/ 10^6 spleen cells. So-called "background" sheep erythrocyte antibody forming cells found in the spleens of unimmunized irradiated chickens were absent in spleens of bursectomized-irradiated birds.

1135 IMMUNOLOGICAL AND SEROLOGICAL INVESTIGATIONS IN PREGNANCY AND GENITAL CARCINOMA. (Ger.) Kadach, D. (Women's Clin., Humboldt U., Berlin, Germany). *Zbl Gynaek* 92(48):1577-1580, 1970.

The immunological relationship of a pregnancy dependent α_2 -globulin detected in sera of some patients with mammary gland carcinomas and a protein detected specifically in the sera of patients with ovarian carcinoma was investigated. Ouchterlony tests were performed with serum or carcinomatous tissue homogenates obtained at surgery from 3 groups of patients: I) 7 with mammary gland carcinoma (10 g tissue samples); II) 10 with uterine carcinoma (5 g tissue samples) and III) 10 with ovarian carcinoma (5 g tissue samples). None of the sera or cancer tissue homogenate samples obtained from group I and II produced any precipitin reaction when tested against rabbit antipregnancy serum, whereas serum from 6 and cancer tissue homogenates from 4 patients with ovarian carcinoma exhibited positive reactions. All positive tests were obtained in cases involving histologically confirmed hormone active tumors which probably originated in the estrogen producing ovarian structures. No relation to the α_2 -globulin was established; the positive reactions seemed to be due to an increase in certain carrier proteins which occurred with the increased estrogen secretion.

1136 CHANGE IN THE TYPE OF RADIATION CELL-KILLING ON HUMAN LYMPHOCYTES AFTER BLAST FORMATION BY PHYTOHEMAGGLUTININ. (E.) Sato, C. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan). *Int J Radiat Biol* 18(5):483-485, 1970.

Cell-death caused by radiation was investigated in human lymphocytes stimulated by phytohemagglutinin (PHA) and in unstimulated cells. Cells were exposed to 150-2000 rads of radiation, and the percent of cells surviving was recorded at 0-100 hr after radiation. Small lymphocytes without PHA began to die 10 hr after 500 rads of irradiation; after 40 hr 95% of these cells were lost. PHA-stimulated lymphocytes survived longer, with cell deaths beginning approximately 40 hr after radiation exposure. PHA-stimulated cells exposed to 150 rads exhibited 55% survival 80 hr after radiation, while cells exposed to 2000 rads exhibited 20% survival at this point. The addition of PHA apparently protected small lymphocytes from early normal interphase death, but changed the type of cell death to one related to mitosis. Mitotic block apparently accounted for more cell loss at lower doses of radiation than did cell death *per se*, with the latter accounting for more cell loss at higher radiation doses.

1137 CHANGES IN THE CARBOHYDRATE METABOLISM OF MITOGENICALLY STIMULATED HUMAN PERIPHERAL LYMPHOCYTES: I. STIMULATION BY PHYTOHEMAGGLUTININ. (E.) Roos, D. (Netherlands Red Cross Blood Transfusion Service, Amsterdam) and J. A. Loos. *Biochim Biophys Acta* 222(3):565-582, 1970.

An investigation into the manner in which energy demands are met in the initial stages of human peripheral lymphocyte mitogenic nonspecific stimulation through incubation with phytohemagglutinin are studied along with the effects of various inhibitors on this activity. Decrease of ATP + ADP was accelerated by phytohemagglutinin during the first 2 hr of

incubation followed by an increase to original levels, whereas phosphate incorporation was significantly higher in phytohemagglutinin stimulated lymphocytes after 180 min of incubation with further increase occurring after 4 hr. Aged erythrocytes responded to adenosine + pyruvate with increased levels of ATP, ADP and 2,3-diphosphoglycerate. Increased production of lactate from 39 to 65 μ moles per 1×10^{10} lymphocytes per hr occurred in the presence of adenosine and pyruvate. Moniodoacetic acid caused the lymphocyte level of glucose-6-phosphate to double during the 1st hr of incubation, and then it remained constant for an hour and then decreased. 2,3-Diphosphoglycerate decreased about 80% within 30 min, and lactate and pyruvate production was completely blocked with no changes observed when phytohemagglutinin was added. Potassium cyanide stimulated lactate production to 90%, phytohemagglutinin, 315%, and the combination of KCN and phytohemagglutinin, 590%, while pyruvate production was slightly inhibited and glycerol production greatly stimulated. *In vitro*, glycolysis is the main energy source for phytohemagglutinin stimulation of lymphocytes since inhibitors of glycolysis (moniodoacetic acid and NaF) completely block this action while cyanide does not.

- 1138 HYDROCORTISONE AND PHYTOHEMAGGLUTININ EFFECT UPON THE RNA SYNTHESIS IN THE AGGREGATE ENZYME OF HUMAN LYMPHOCYTES. (E.) Ono, T. Fac. Med. U. Tokyo, Japan), H. Terayama and K. Sakao. *Life Sci* 9(21):1217-1223, 1970.

The mechanism of phytohemagglutinin (PHA) stimulated RNA synthesis was investigated in aggregate enzymes prepared from nuclei of peripheral human lymphocytes. In the presence of 0.4 M ammonium sulfate, the addition of PHA or hydrocortisone had no effect on RNA synthesis in the lymphocyte aggregate system as measured by the incorporation of 3 H-uridine triphosphate or 3 H-uridine triphosphate into RNA. With or without PHA and/or hydrocortisone, lymphocytes incorporated between 2.0-2.5 mole of cytidine monophosphate/50 μ g DNA. Incorporation of nucleotides was not enhanced by the addition of calf thymus DNA to the incubation mixture or by the addition of PHA or hydrocortisone to aggregate enzymes in the presence of *E. coli* polymerase. Aggregate enzymes prepared from lymphocytes preincubated for 4 hr with PHA synthesized more RNA in the presence of ammonium sulfate than the enzyme from control lymphocytes (3 H-uridine triphosphate incorporation was 3.85 pmole/50 μ g DNA for preincubated cells, and 2.44 in controls). Differences in RNA synthesis between enzymes prepared from preincubated lymphocytes and controls disappeared in the presence of *E. coli* RNA polymerase. Addition of hydrocortisone (100 μ g/ml) and A in the preincubation medium prevented the increase in RNA synthesis in the aggregate enzyme assayed in the ammonium sulfate system. These findings appear to suggest that the PHA-stimulated RNA synthesis in lymphocytes is mainly due to an increase in RNA polymerase activity.

- 1139 URINARY IMMUNOGLOBULINS IN PATIENTS WITH CANCER. (E.) Lindstrom, F. D. (U. Minnesota Hosp., Minneapolis), R. C. Williams, Jr. and A. Theologides. *Scand J Haemat* 7(5):383-388, 1970.

Immunoglobulins in the urine of 63 cancer patients, 33 of which were cancer of the breast and cancer of the colon, were studied. Elevated levels of urinary light chain immunoglobulins were noted in only a few cases, and a marked domination of kappa-type light chains was seen in these cases. Twenty-four hr urine specimens were taken and examined for monoclonal immunoglobulins, primarily of the Bence Jones type. Eight patients with reproductive system or gastrointestinal tract cancers showed elevated levels of light chain immunoglobulins, with kappa light chain values in mg/24 hr ranging from 69-302, IgG values ranging from 0-64, and lambda-type values ranging from 0-59. IgG and lambda immunoglobulin values exceeded zero in 2 and 4 cases, resp. The preponderance of kappa-type light chain immunoglobulins recorded for these patients is similar to observations in leukemia and lymphoma patients; however, these immunoglobulins were apparently not of the Bence Jones type, since they lacked the electrophoretic homogeneity of these proteins.

- 1140 PRODUCTION OF 19S AND 7S ANTIBODIES BY CANCER PATIENTS. (E.) Levin, A. G. (Mem. Hosp. Cancer Allied Dis., New York, N. Y.), M. P. Cunningham, A. K. Steers, D. G. Miller and C. M. Southam. *Clin Exp Immunol* 7(6):839-849, 1970.

Titers of 19S and 7S antibodies produced by cancer patients were compared with titers produced by healthy controls. "7S Antibody" was distinguished by persistence of activity after incubation with mercaptoethanol and rapid elution from a DEAE cellulose column by low ionic strength buffer at pH 7.4; "19S antibody" was distinguished by the opposite characteristics. Cancer patients included patients with epidermoid carcinoma and adenocarcinomas, and patients with Hodgkin's disease, lymphocytic leukemia and myeloma. Antibody titrations were determined after injection of 17D yellow fever live virus vaccine. Antibody titers were similar in cancer patients and in controls. At 1 and 2 wk after injection of yellow fever vaccine, mean titers of 7S antibody were less than 1:10 for all subjects; by 4 wk, titers for carcinoma patients were at 1:80, while titers for controls and lymphoma patients were both at 1:20. Titers of 19S antibody were negligible in all groups until about 1 wk after injection with vaccine; by 3 wk, however, controls, carcinoma patients, and lymphoma patients had titers of 3, 2, and 1.5 tubes of 2-fold serum dilutions of decreased antibody titer by mercaptoethanol, resp. By 6 wk after vaccine injection, 7S and 19S antibody titers showed little change in any group. Antibody production was generally delayed somewhat in carcinoma patients; viremia was detected in 1 of 8 controls, in 4 of 20 carcinoma patients and in 2 of 3 lymphoma patients. None of the patients produced interferon.

143 NEOPLASTIC CONVERSION *IN VITRO* OF MOUSE CELLS: CYTOLOGIC, CHROMOSOMAL, ENZYMATIC, GLYCOLYTIC AND GROWTH PROPERTIES. (E.) Sanford, K. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), B. E. Barker, R. Parshad, B. E. Westfall, M. Woods, J. L. Jackson, D. R. King and E. V. Peppers. *J Nat Cancer Inst* 45(6):1071-1096, 1970.

Presumably virus-free ALBM-2 mouse embryo cells were observed for progression of cytologic changes, growth-pattern change, glycolytic alteration capacity and inhibitor response indicative of spontaneous changes occurring with neoplastic conversion. Three lines of cells in horse serum had undergone neoplastic conversion by approximately 145-164 days, with latent periods averaging 14 days; a lower incidence of tumors and latent periods averaging 73 days occurred in cells cultured in fetal calf serum. An increase in cytoplasmic basophilia as one of the earliest cytologic changes associated with neoplastic conversion. Neoplastic cells had a high nuclear-cytoplasmic ratio, and the basophilic cytoplasm was densely filled with free ribosomes and polysomes. No changes in enzyme activity could be correlated with neoplastic conversion. Increases in rates of anaerobic glycolysis with time were seen in cells maintained on horse serum but not in cells in fetal calf serum; the former were also less sensitive to glycolytic inhibition by a specific anti-insulin (anti-hexokinase) inhibitor than the latter. The other characteristic change associated with neoplastic conversion was higher saturation density than normal cells and a tendency for cells to adhere less tightly to the glass substrate. Reduced substrate dependency, rather than loss of contact inhibition of mitosis, may account for some of the changes observed in neoplastic conversion of cells under specific culture conditions.

144 THE ULTRASTRUCTURAL DISTRIBUTION OF SEVERAL PHOSPHATASE ENZYMES IN MOUSE MAMMARY TUMOR (STEM. (E.) Misfeldt, D. S. (U. Oregon Med. Sch., Portland), R. D. Cardiff and S. R. Wellings. *Lab Invest* 23(6):640-648, 1970.

The distribution of 3 phosphatase enzymes in tissues representing various stages in the development of a mouse mammary adenocarcinoma were investigated. Nucleoside phosphatase, thiamine phosphatase, and acid phosphatase were assayed in prelactating mammary tissue, lactating mammary tissue, mammary hyperplastic nodules, mammary hyperplastic outgrowths, and mammary adenocarcinoma. Nucleoside phosphatase reaction products were found on the basal and lateral membranes of cells in all 6 tissue-stage samples, while reaction products were found on apical cell membranes only in hyperplastic outgrowth cells and adenocarcinoma cells. Most enzyme observations were made by electron microscope cytochemistry. Control mice without evidence of tumor development showed no evidence of reaction products in the absence of enzyme capture agents or enzyme substrates. The ultrastructural distribution

of all enzyme products was identical in prelactating and lactating mammary tissues. Distribution of nucleoside phosphatase reaction products in normal ductal tissue outgrowths was similar to the distribution in lactating mammary epithelium, with the product distributed along the basal and lateral cell membranes. In hyperplastic alveolar nodules, nucleoside phosphatase was distributed as it was in prelactating and lactating mammary tissue; however, reaction products of this enzyme in hyperplastic nodule outgrowths thought to be of high tumorigenic potential were distributed in the apical cell membranes to a greater extent than was observed in more benign hyperplastic nodules. The apical microvilli were the site of nucleoside phosphatase reaction products in adenocarcinoma cells, again contrasting with the distribution of reaction products among more benign cells where they were more often found on basal and lateral cell membranes. Acid phosphatase was distributed similarly in tissues undergoing nodulogenesis and tumorigenesis. Thiamine phosphatase, present along the basal cell membranes in lactating cells, was absent from the basal cell membranes in adenocarcinoma cells. In tumor cells, nucleoside phosphatase was found in vacuoles associated with virus-like type A particles. The findings appear to indicate that changes in enzyme activity in cell surface membranes preceded tumorigenesis.

1145 PATHOGENESIS AND HORMONAL PROPHYLAXIS IN EXPERIMENTAL DYSHORMONAL DISEASES OF MAMMARY GLANDS. (Rus.) Dmitriev, V. N. (Izhevsk Med. Inst., USSR). *Biull Exp Biol Med* 70(11):90-92, 1970.

The role of sex hormones in the development of mammary gland tumors was studied in 466 randombred female mice. The effect of testosterone and ovariectomy was investigated in 191 mice subjected to continuous electric light exposure (75-200 watt) during the whole experimental period and in 155 mice subjected to synestrol treatment (200 mg s.c., once a wk). Ovariectomy was performed 2 wk before the start of the experiment and testosterone (0.4 mg once a week) was given starting from the 1st day of the experimental period. The effect of testosterone was also studied in a group of 120 mice treated with dimethylbenzanthracene (DMBA, 1 mg in 0.2 ml peach oil injected into the right mammary gland once). Hyperplasia and tumors developed in 90% of the control animals exposed to electric light; prophylactic testosterone treatment or ovariectomy prevented tumor development and decreased the incidence of hyperplasia (8.6% and 15%, resp.) The administration of synestrol induced hyperplasia and tumor development in 95% of the mice in the second experiment. Testosterone treatment and ovariectomy prevented tumor development and decreased the incidence of preneoplastic conditions to 48% and 45%, resp. DMBA induced hyperplasia in 70% of mice, squamous epithelial or adenocarcinoma in 17% and sarcoma in 12% of the animals. Testosterone prevented cancer development and decreased the incidence of hyperplasia to 18%, increasing the life span of the experimental animals an average of 9 wk. The basic endocrine alterations in all experimental groups seemed to be related to variations in follicle stimulating hormones and estrogens.

- 1146 CYTOGENETIC STUDIES IN MYELOPROLIFERATIVE DISORDERS DURING TRANSFORMATION INTO LEUKAEMIA. (E.) Jensen, M. K. (Gentofte Hosp., Copenhagen, Denmark) and P. Philip. *Scand J Haemat* 7(5):330-335, 1970.

Two female patients aged 68 and 79 yr-old with myeloproliferative disorders, (one of which transformed into leukemia) showed abnormal cytological features on cytogenetic study. Pathology in the first case included retroperitoneal hematoma, myeloblastic and myelocytic proliferation, and numerous megakaryocytes. Pathology in the second case included hypoplastic bone marrow, extramedullary hemopoiesis, and numerous megakaryocytes. In the first case, the bone marrow showed 5 abnormal metaphases out of 50 tested. Metaphases contained 46 chromosomes with 2 supernumerary acentric fragments. Five metaphases showed structural aberrations of the chromosomes including breaks of the chromosome and chromatid material. In a marrow aspirate taken at a later date, 22% of the cells showed these features. In the second case, about 25% of the metaphases contained 44 chromosomes with a chromosome missing in groups C and D; in a marrow aspirate taken at a later date, 80% of the metaphases showed this aberration. Supernumerary acentric fragments were found in 3 of 15 cells with 44 chromosomes. Chromosomal abnormalities were present in erythroblasts as well as in white cells. A clonal evolution of abnormal cells was apparently operating in the second case. It was concluded the abnormal cell lines in patients with myeloproliferative diseases may represent a clone of neoplastic cells.

- 1147 MICROCHROMOSOMES IN HUMAN PRELEUKEMIA AND LEUKEMIA. (E.) Pierre, R. V. (Mayo Clin. Rochester, Minn.), H. C. Hoagland and J. W. Linman. *Cancer* 27(1):160-175, 1971.

Microchromosomes were detected in bone-marrow preparations from 9 patients, 7 of whom had myelomonocytic leukemia, 1 of whom has a preleukemic syndrome which degenerated into acute myelomonocytic leukemia, and 1 of whom remained in the preleukemic phase at the end of the study. In some karyotype preparations, 1 microchromosome was found, and in others, as many as 4. The microchromosomes appeared to be marker chromosomes rather than acentric chromosome fragments. Evidence for this conclusion included the fact that in 4 of the 9 cases observed, microchromosomes similar in number and appearance occurred in each cell division episode. This indicated that the microchromosomes were not fragments, for fragments are unstable and generally are lost after a single cell division. It was also thought that the microchromosomes identified 1 or several clones of leukemic cells.

- 1148 INTERRELATIONS OF THE HISTOLOGIC TYPES OF HODGKIN'S DISEASE. (E.) Strum, S. B. (Sch. Med. U. Chicago, Ill.) and H. Rappaport. *Arch Path* 91(2):127-134, 1971.

The histological evolution of Hodgkin's disease (HD) was investigated in a retrospective study of 81

cases. In 13 cases the initial pretreatment lymph node biopsy section was classified as HD with lymphocytic predominance; a second or third biopsy 0.8-11.6 yr later in 7 of these cases revealed HD with mixed cellularity in 2 cases, HD with lymphocytic depletion in 3 cases, HD with nodular sclerosis in 1 case and 1 case of lymphoreticular type HD. In 48 cases the initial biopsy sections showed features of HD with nodular sclerosis; later biopsies 0.1-17.3 yr later showed HD with mixed cellularity in 3 of these cases and HD with lymphocytic predominance in 1 case. Of 7 cases in which the initial biopsy showed many lacunar cells without band formation, 5 developed into classical nodular sclerosing HD in subsequent biopsies. Of 7 cases classified from the initial biopsy as HD with mixed cellularity, 2 revealed HD with lymphocytic depletion in 0.1-1.6 yr. One of 2 cases of HD with lymphocytic depletion changed to HD with mixed cellularity in 2.5 yr. Four cases in which the initial biopsy could not be classified evolved into HD with lymphocytic predominance, nodular sclerosis, mixed cellularity and lymphocytic depletion, resp.

- 1149 REPORT OF A CASE OF MALIGNANT TRANSFORMATION IN BENIGN MIXED TUMOR OF THE LACRIMAL GLAND. (E.) Riley, F. C. (Mayo Clin., Rochester, Minn.) and J. W. Henderson. *Amer J Ophthalmol* 70(5):767-770, 1970.

A case of malignant transformation in an originally benign mixed tumor of the lacrimal gland was reported. The patient, a woman, first presented in 1929, at which time an orbital tumor was excised which was concluded to be a typical benign mixed tumor of the lacrimal gland. In 1969, the patient returned to the hospital, and a malignant sarcomatous lacrimal tumor was excised. The malignant tumor showed spindle-shaped cells with nuclear atypism. Numerous mitotic figures were present and multinucleated cells were seen. Although epithelial cells in the zone of transition were hyperplastic, no certain evidence of carcinomatous transformation was observed. There was no sign of invasion of the muscle.

- 1150 IMMUNOPATHOLOGY OF ORAL LEUKOPLAKIA. (E.) Lehner, T. (Guy's Hosp. Med. Sch., London, England). *Brit J Cancer* 24(3):442-446, 1970.

In vitro studies of transitional changes from leukoplakia to carcinoma were studied through lymphocyte response to autologous homogenates of leukoplakia and to a number of antigens in addition to the relationship of uptake of ^{14}C -thymidine to the changes in human tissue from oral lesions. Histological examination revealed stimulation of lymphocyte transformation in most cases of homogenates of leukoplakic tissue studied and a negative correlation existing between ^{14}C -thymidine uptake of stimulated lymphocytes and the number of non-pyroninophilic mononuclear cell infiltration. Hyperkeratotic (grade I) tissue appeared to be associated with the highest rate of lymphocyte transformation and the lowest mononuclear cell infiltration, with a decrease in the former and an increase in the

ter as the histological grading progressed towards carcinoma. On the basis of these studies, additional criteria for the assessment of premalignancy may be established relative to depression of lymphocyte transformation and increase in number of pyroninophilic cells at the site of the lesion.

- 51 CANINE PAPILLOMA: PROGRESSION OF ORAL PAPILLOMA TO CARCINOMA. (E.) Watrach, A. (Coll. Vetr. Med., U. Illinois, Urbana), E. Small and M. T. Case. *J Nat Cancer Inst* 45(5):915-920, 1970.

A male beagle was seen at a veterinary clinic with multiple papillomatous growths involving the oral cavity, tongue and anterior part of the pharynx; the dog was killed 8 months after first examination due to continuing growth of the neoplasms and worsening condition. Squamous epithelial cells characteristic of squamous cell carcinoma were found on autopsy in the posterior portion of the right jaw; the lesion consisted of many ramifying cords, nests and strands of squamous epithelial cells. Mitotic activity and anaplasia were not pronounced; in some areas cords of tumor cells invaded the bone. There were no metastases, but the anterior cervical lymph nodes showed a moderately advanced inflammatory reaction. A relationship may exist between the duration and extent of papillomatosis and the appearance of malignant change. It is also possible that the papillomatosis degenerated to squamous cell carcinoma as a result of a breakdown in the immune system.

- 2 THE HISTOLOGY OF THE PRECANCEROUS ALTERATIONS OF THE LARYNX. (Ger.) J. Sugár. *Arch Klin Exp Ohr Nas Kehlkopfheik* 197(2):142-153, 1970.

Precancerous changes in the larynx are described including the hyperplastic forms of chronic laryngitis, pachydermia laryngitis and papillomas in adults. A review of histological findings over 14 years, of precancerous carcinoma of the larynx, from light- and electron microscopic observations, is presented. On the basis of histological diagnosis, of the 252 noncancerous but suspicious changes, 120 were of the pachydermia type, and 51 were papillomas. The chronic laryngitis cases were included in the first category, since they could not be distinguished histologically from the pachydermia. In 8 of 120 of these cases, and 6 of the papillomas, atypical epithelium was seen. Fibromatous polyps were found in 46 biopsy specimens. In 25 cases of suspected carcinoma or borderline carcinoma cell changes were seen of a carcinoma in situ. The precancerous changes reported in the investigation stem predominantly from specimens taken from 50-60 year-old patients. In the electron microscopic examination, intracellular filaments were seen which could be interpreted as the precursors of cornification. Changes could also be detected in the cytoplasm of the parabasal and energy layer of the membrane, in the form of extracellular invasion. Basal membrane splits of a 0.1

to 0.5 μ diameter were seen through which the cytoplasm reached the connective tissue.

- 1153 PULMONARY CANCER LOCATED ON CICATRIX. (It.) Ajello, L. (Inst. Anat., U. Rome, Italy) and L. Scorretti. *Policlinico* 77(48):1551-1564, 1970.

The role of cicatrization foci in the pathogenesis of lung cancer is illustrated by 13 case reports. The sclerotic foci originating from tubercular cicatrization and localized in the apical region of the lung seemed to undergo a high incidence of neoplastic transformation. Malignant proliferation occurred when these lesions were exposed to specific conditions of biological susceptibility and to persistent chronic irritating stimuli. Long term anoxia of the bronchial cells, accumulation of inhaled carcinogens and their inclusion within the histiocytic elements may constitute contributing factors. In addition to the usually admitted factors contributing to lung carcinogenesis, the pathogenic role of sclerotic foci within the lung parenchyma or the bronchial walls generated from pneumoconiosis (both silica and asbestos-induced) is emphasized.

- 1154 THE RISK OF SUBSEQUENT CANCER DEVELOPMENT IN CAUSTIC STENOSES OF THE ESOPHAGUS. (Fr.) Gaillard, J. (Hosp. Edouard Herriot, Lyon, France), M. Bouchayer and J. P. Haguenaer. *Ann Otolaryng* 87(10-11):637-644, 1970.

Development of esophageal cancer on the site of caustic injury-induced stenosis is illustrated by 4 case reports. Two of the patients suffered accidental burning with potassium hydroxide at the age of 5 and 3 yr and developed esophageal keratinizing epithelioma at age 63 yr and 50 yr, resp. The other 2 cases were exposed to sodium hydroxide burning at the age of 42 and 4 yr and developed similar neoplasms at the age of 72 and 42, resp. The main features of these neoplasias were the causticity of the stenosis inducing agent, the site of their development (approximately 21 cm from the dental arch, the usual site of caustic agent-induced stenoses) and the long latency periods ranging from 29 to 57 yr. The histological features of these keratinized epitheliomas were specific for their origin from scar tissue as opposed to the tumors arising within the mucosal tissues.

- 1155 POLYPOGENESIS OF GASTRIC MUCOSA. (E.) Muto, T. (Fac. Med., U. Tokyo, Japan) and K. Oota. *Gann* 61(5):435-442, 1970.

Histological examinations were conducted on 142 adenomatous polyps of the gastric mucosa obtained from 89 patients who underwent resection of the stomach. The component of these polyps responsible for their protrusion was the proliferation of ducts not connected to the gastric glands. Characteristic features of these polyps included an elongation and dilation of the gastric pits, hyperplasia, budding and branching of proliferating ducts, interstitial

PATHOGENESIS

edema, cell infiltration, and capillary proliferation. An unusual eosinophilic duct pattern was observed in adenomatous polyps and at the edges of ulcers and over erosion scars; these ducts exhibited eosinophilic epithelium with prominent nucleoli, and their cytoplasm was more pyroninophilic than that of normal gastric pit cells. It was speculated that the genesis of adenomatous polyps proceeded through an initial stage characterized by focal hyperplasia of ducts and glands, followed by ductal proliferation culminating in the development of the classic adenomatous polyp.

- 1156 THE OCCURRENCE OF DESMOIDS IN PATIENTS WITH FAMILIAL POLYPOSIS COLI. (E.) McAdam, W. A. F. (Gen. Infirm., Leeds, England) and J. C. Goligher. *Brit J Surg* 57(8):618-631, 1970.

The occurrence of desmoid tumors in patients with familial polyposis coli was reviewed as it is documented in the literature, and 4 new cases were reported. In the literature, there were 89 cases in which desmoids appeared in patients with polyposis coli; the familial nature of the disease was certain in 50 cases, and probable in 10. The 4 new cases were 3 males and 1 female 15-33 yr-of-age. In 1 case, desmoid tumors were found on the abdominal wall 2 yr after the diagnosis of polyposis coli; in another patient, desmoids were found in the stomach 1 yr after a colectomy for polyposis coli; this patient also had osteomas on the lower jaw. The third patient also presented with osteomas on the jaw and developed desmoids on the surgical scar left after colectomy for polyposis. The fourth patient developed a desmoid at the site of a leg fracture; later she underwent colectomy for multiple abdominal neoplasms, and it was found that carcinoma had involved her liver. Desmoids are hard, fibrous tumors occurring usually in the flat muscles of the anterior abdominal wall; they appear to be infiltrating fibromas of fascial and aponeurotic origin.

- 1157 STATISTICAL MODEL OF THE NATURAL HISTORY OF CERVICAL CARCINOMA: II. ESTIMATES OF THE TRANSITION TIME FROM DYSPLASIA TO CARCINOMA *IN SITU*. (E.) Barron, B. A. (Rockefeller U., New York, N.Y.) and R. M. Richart. *J Nat Cancer Inst* 45(5):1025-1030, 1970.

The probability of cervical dysplasia progressing to cervical carcinoma *in situ*, and the time required for this transition were estimated in terms of a statistical model of the natural history of cervical carcinoma derived from age-specific prevalence rates of dysplasia, carcinoma *in situ*, and invasive cervical carcinoma established from a study of 557 women in Barbados, West Indies. This sample was part of a larger population of 11,814 women from Barbados (women in the 20-39 yr age group were over-represented in the larger population). The proportion of women with severe dysplasia rose with increasing age, with 3.9 cases/1000 population in the 20-24 yr cohort, and 7.1 cases/1000 in the 30-34 yr cohort. The highest weighted mean number of dysplasia cases was 0.494 for very mild dysplasia.

The mean time for transition to carcinoma *in situ* from the very mild dysplasia class was estimated as 68.8 months, and transition time from mild dysplasia to carcinoma *in situ* was 37.3 months; transition times from moderate and severe dysplasia to carcinoma *in situ* were 29.4 and 11.5 months, resp. Prevalence rates for all dysplasias and the ratio of mean transition time to total time were found to be concordant. The time of transition to carcinoma *in situ* and probability of transition were associated with the total number of pregnancies, but were not associated with age at first coitus or with age at first pregnancy. In all classes of dysplasia (very mild, mild, moderate and severe) women who had 2 or less pregnancies had higher relative prevalence ratios than women who with more than 2 pregnancies. The statistical model presented appears to be capable of detecting small changes in the transition probabilities and transition times among different subsets of a test population.

- 1158 RESPONSE OF THE RHESUS MONKEY UTERINE CERVIX TO CHRONIC ESTROGENIC STIMULATION. (E.) Graham, C. E. (Yerkes Reg. Primate Res. Ctr., Emory U., Atlanta, Ga.). *Amer J Obstet Gynec* 108(8):1192-1196, 1970.

The replacement of the columnar epithelium in the endocervix of rhesus monkey by stratified squamous epithelium following chronic estrogen stimulation was investigated in young adult female rhesus monkeys. Monkeys were ovariectomized and treated with estrone (1.5 mg/day) for 2-12 wk; another group of intact monkeys were treated with estradiol benzoate (0.023 mg/day for 4 days). At the end of the treatment period, sections from the uterine cervix and from the lower portion of the uterine corpus were prepared for electron microscopy. In intact monkeys showing no evidence of endogenous estrogenic stimulation, there were no detectable stratified elements in the columnar tissue of the lower part of the endocervical canal. Following treatment with estradiol in ovariectomized animals, the cervical stratified epithelium was thickened and fully cornified, and epithelial cells were observed lying immediately beneath the columnar cells of the endocervix. Similar immature stratified elements could be seen in intact monkeys showing evidence of endogenous estrogenic stimulation. In all ovariectomized chronically treated animals, areas of incompletely cornified squamous stratified epithelium occupied much of the surface of the endocervical canal, approaching the junction with the endometrial region after 8-12 wk treatment. Since foci of stratified cells occurred normally throughout the cervical canal in controls, it was concluded that cervical epidermization is not caused by metaplasia of the columnar cells.

- 1159 CHRONIC CYSTIC MASTITIS AND CANCER: A REPORT OF 206 CASES AND THEIR POSSIBLE RELATIONSHIP WITH TWELVE CARCINOMAS. (Fr.) Chardon, C. (Reg. Anti-Cancer Ctr., Nancy, France), A. Varrault, and R. M. Parache. *Bull Cancer* 57(2):251-268, 1970.

206 women 19-63 yr-of-age with chronic cystic mastitis 12 developed cancer of the mammary gland within 4 yr of observation. Two of these cancers probably preceded diagnosis of cystic mastitis, and occurred within 1 yr and 6 cancers developed 2-4 yr after diagnosis. The latter six cases of cancer developed at an average age of 45 yr on the same date that clinical manifestation of chronic mastitis occurred previously. The incidence of mammary cancer was 7.5-fold greater than corresponding populations of French women unaffected by chronic cystic mastitis. Histologically these cancers appeared to be epitheliomas which are usually considered to be a specific result of malignant transformation of cystic mastitis. Evidence to support this evolution is provided by the presence of structures with epithelial hyperplasia exhibiting patterns intermediate between cystic mastitis and neoplastic structures.

50 ATYPICAL EPITHELIAL HYPERPLASIA OF THE FALLOPIAN TUBES IN CASE OF ENDOMETRIAL CARCINOMA. (Ger.) Dallenbach-Hellweg, G. (Mannheim Univ., U. Heidelberg, Germany) and W. Rom. *Klin Wochenschr* 48(23):1426-1427, 1970.

Epithelial hyperplasia of the fallopian tubes was found in 50 postmenopausal women with endometrial carcinoma who had a history of long term estrogen treatment. The tissues examined exhibited cells with enlarged irregular polymorphic nuclei containing large amounts of chromatin; high levels of DNA was contained in the cytoplasm. When compared to the carcinomatous endometrial epithelium, a close similarity between the two hyperplasias could be noticed. The hyperplastic epithelium presented no invasive features; this type of proliferation may have preceded the development of endometrial carcinoma; its stationary character may be due to the particularly long latency period for malignant development, characteristic at this site. Postmenopausal women without endometrial carcinoma had fallopian tubes lined with atrophic epithelium as expected. The hyperplastic alterations at both sites seemed to have been induced by the same hormonal stimulation since both sites are known target organs for estrogens.

1 THE ADENOMATOID TUMOR: FINE STRUCTURAL EVIDENCE FOR A MESOTHELIAL ORIGIN. (E.) McKay, B. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston), J. L. Bennington and R. W. Skoglund. *Cancer* 27(1):109-115, 1971.

An adenomatoid tumor obtained from the epididymis of a 9-yr-old male presented the appearance of a typical adenomatoid tumor, with numerous thin-walled channels lined by cells having irregular, microvilli-like projections on their luminal surface under light microscope; scattered foci of lymphocytes were seen. Electron microscopy showed that the lining cells were cuboidal in shape with a spherical or ovoid nucleus. Adjacent cells were joined by terminal bars and by elaborate series of desmosomes. Cell cytoplasm included scattered microsomes; and free ribosomes were abundant. There were areas between adjacent cells where apposed cell membranes separated

to form an anastomosing network of secondary channels communicating with the main channel lumens and rarely with stromal space. Within the channel lumens were aggregates of cytoplasmic debris containing disintegrating mitochondria and myelin figures. Round cells which did not resemble any specific blood or connective tissue cells were also present in the channel lumens; these cells may have migrated from surrounding stroma into the channel lumen. The irregular microvilli, the terminal bars joining adjacent cells, the desmosomes, and the appearance of secondary channels suggested that the adenomatoid tumor was of mesothelial origin.

1162 THE PHYSICAL BASIS OF PROTEIN MODIFICATION AND ITS RELATION TO THE PROBLEM OF CARCINOGENESIS. (Ger.) Caro, W. (Phys. Chem. Inst., Humboldt U., Berlin, Germany). *Arch Gesehwulstforsch* 36(2):127-131, 1970.

A type of irreversible protein conformational alteration which seems to have a role in carcinogenesis was investigated. Kinetic determinations on methemoglobin and metmyoglobin (Methb) allowed the derivation of relationships involving native protein (N), S1 (with intramolecular modification), S2 (with intermolecular modification), and their denaturation products DN, DS1, DS2 and rate constants and activation energies EDN, ES1 and ES2. Benzene increased all rate constants and decreased ES1. Extrapolation of Methb-data to 37°C revealed that formation of S1 is equal to 5% after 50 days (the average age of an erythrocyte) and exceeded all the other Methb-modifications. The addition of 0.0027 moles of benzene (a modification enhancing compound) increased the formation of S1 by 12%. The properties of the modified S1-methb compared to N-protein consisted of a 5% increase in helix content (as opposed to protein denaturation) and an increase of phenylalanine side chain van der Waal's linkage; the structure was stable against denaturation, and its environment was not subject to alterations, indicating the maintenance of biological activity; minor shifting in solubility occurred and full maintenance of crystallizing properties was observed. These data seem to indicate that protein modifications, can be enhanced by means of aromatic carcinogens. The possibility that such protein modifications, induced by physical, chemical and viral agents, may constitute part of the etiology of carcinogenesis is reviewed.

1163 RELATIONSHIPS BETWEEN CIRRHOSIS AND LIVER CANCER. AN EXPERIMENTAL STUDY. (Fr.) Robert, P. K. (Hosp. St. Joseph, Paris, France). *Soc Med Paris* 173(6):5-8, 1970.

1164 CARCINOMA ARISING IN AN ANAL FISTULA. (Nor.) Gronmark, T. (Telemark Central Hosp., Norway). *T Norsk Laegeforen* 90(24):2258-2259, 1970.

- 1165 LIVER CANCER DIFFERENTIALS IN IMMIGRANT AND LOCAL-BORN CHINESE IN SINGAPORE. (E.) Shanmugaratnam, K. (Fac. Med. U. Singapore) and C. Y. Tye. *J Chron Dis* 23(5-6):443-448, 1970.

The differential incidence of liver cancer among immigrant Chinese and local-born Chinese in Singapore was investigated. Ninety-nine cases of liver cancer were examined and compared with 1044 control hospital patients. There were 79 male liver cancer cases and 20 female cases; 68 of the male cases occurred in patients from 40-69 yr. Persons born in China accounted for 73% of the liver cancer patients, and 53% of the hospital controls. The Chinese-born account for 17% of the Chinese population of Singapore. It appeared from the data that immigrant Chinese had a 75% higher risk of contracting liver cancer than local-born Chinese. All the Chinese-born liver cancer patients had resided in Singapore for more than 10 yr; 51% of them had been born in the Kwangtung province of China, and 63% in the Fukien province. The excess in liver cancer cases among Chinese-born immigrants to Singapore is less than that found in previous studies.

- 1166 LEUKAEMIA IN KENYA. (E.) Kasili, E. G. (Med. Res. Lab., Nairobi, Kenya) and J. R. Taylor. *E Afr Med J* 47(9):461-468, 1970.

The incidence of leukemia in the African population of Kenya since 1967 was investigated. Yearly occurrence of the disease showed a fairly constant pattern, 40 cases having been recorded in 1967, 43 in 1968 and 44 (projected) in 1969. The minimum incidence of leukemia was estimated as 3.4 cases/100,000 population based on figures from the Kiambu District; incidence of leukemia in the United States and Denmark by comparison were 8.6 and 8.4/100,000 male population. Males were found to be more susceptible to leukemia in Kenya than females; in the 0-14 yr age group, there were 16 male and 8 female leukemia patients on record, and in the over-15 yr age group there were 50 males and 31 females. Chronic lymphatic leukemia showed the strongest male predominance, the male-female ratio for this condition being 1.80:1.00. The most common type of leukemia in Kenya was acute myelogenous leukemia, accounting for 28 of 104 cases; chronic myeloid leukemia comprised 27 cases, and chronic lymphatic leukemia, 17 cases. Chronic lymphatic leukemias showed higher hemoglobin values than other types of leukemia. Inadequate diagnosis appeared to be an important factor in the low figures for leukemia incidence in Kenya.

- 1167 INCIDENCE OF MALIGNANT NEOPLASMS IN THE CRACOW DISTRICT IN RELATION TO THE PLACE OF LIVING. (Pol.) Kolodziejska, H. (Oncol. Inst. Cracow, Poland). *Nowotwory* 20(4):305-310, 1970.

The average annual incidence of malignant neoplasia in the district of Cracow was 158 in females and 149 in males per 100,000 population according to the available records for 1965-1968. This inci-

dence appeared to be higher within the urban area of Cracow (227 in females and 180 in males) than in the country (177 in females and 150 in males) per 100,000 population. A higher incidence in lung cancer in both males and females was noticed within the urban area (24% and 5%, resp.) than in the country (18% and 4%, resp.). The incidence in gastric cancer appeared to be lower in the urban area of Cracow for both males and females (15% and 8%, resp.) than in the country (26% and 16%, resp.). The incidence of cancer of the cervix was 17% in the urban area and 14% in the country. It is suggested that these differences between cancer incidences in urban and country areas may be due to environmental factors, regardless of the better records available for the urban areas.

- 1168 LIVER CANCER IN BEDOUINS OF THE NEGEV: AN ETIOLOGICAL AND MORPHOLOGICAL STUDY. (E.) Gussarsky, J. (Negev Central Hosp., Beer-Sheva, Israel), M. Gross and G. M. Goldberg. *Path Microbiol* 35(1-3):184-188, 1970.

The pathology of liver tumors discovered in 14 cases in the Negev (Israel) was examined. Though Jews outnumber Bedouins in the Negev by 8:1, 7 of the 14 cases of liver cancer studied were Bedouins. Material was taken from 8 autopsies and 6 biopsies of livers of 7 Bedouin patients (all males) and 7 Jews (2 females). Patients ranged in age from 31-70 yr-old. All livers showed cirrhosis, and all biopsy specimens were diagnosed as hepatocellular hepatoma. Four autopsy cases were hepatocellular hepatomas, and 4 were cholangiocellular hepatomas. Metastases were found in all autopsy cases, with sites of metastases including lungs, lymph nodes, brain and thyroid. The excessive occurrence of liver cancer in Bedouins in this study could not be explained; hepatotoxic agents were excluded, and a racial factor predisposing to liver cancer was suggested.

- 1169 GEOGRAPHIC PATHOLOGY OF ORAL, ESOPHAGEAL, GASTRIC, AND INTESTINAL CANCER IN CHILE. (E.) Zaldivar, R. (Hlth. Res. Inst., Fairleigh Dickinson U. Madison, N. J.). *Z Krebsforsch* 75(1):1-13, 1970.

The incidence and geographic distribution of cancer of the alimentary tract in Chile was investigated in a survey of mortality rate statistics from that country. Cancer of the oral cavity and pharynx accounted for 81 of 7,618 deaths from cancer of the alimentary system in 1960; males made up 51 of these cases. Malignancies of the tongue and pharynx accounted for 18 and 33 of the 81 deaths, resp. Esophageal cancer accounted for 356 of the total alimentary cancer deaths, of which 228 were among males. Death from esophageal cancer was more frequent in northern provinces of Chile than in the southern provinces; the age-adjusted death rates from the northern province of Aconagua was 11.1 deaths/100,000 population, and from the southern province of Bio-Bio, the rate was 0.5/100,000. In all alimentary tract cancers except cancer of the mouth and pharynx and

cancer of the small intestine, the frequency of deaths increased with increasing age, with the number of deaths usually leveling off around age 75-. The age-adjusted death rates for stomach cancer among females in Chile are the highest in the world (12.2 deaths/100,000 population in 1964). The highest death rate for stomach cancer in Chile was 75.8 deaths/100,000 recorded in the central province of Antofagasta in 1962, and the lowest death rate was 18.1 deaths/100,000 in the southern province of Magallanes the same yr. High death rates from alimentary tract cancer were often recorded in agricultural provinces, indicating that a causal relationship may exist between the use of nitrate fertilizers and the incidence of alimentary tract cancer in Chile.

MESOTHELIOMA IN SCOTLAND. (E.) McEwen, J. (Dept. Soc. Occup. Med., U. Dundee, Scotland), Finlayson, A. Mair and A. A. M. Gibson. *Brit Med* (5735):575-578, 1970.

A retrospective survey of mesothelioma cases in Scotland during the period 1950-1967 was performed, and the possibility of an association between mesothelioma and exposure to asbestos was investigated. Eighty cases of mesothelioma were collected, and compared with controls comprised of non-cancer patients with no exposure to asbestos and patients with cancer other than mesothelioma who reported exposure to asbestos. Of the 80 mesothelioma cases, 73 were men and 7 were women; 69 of the men had pleural tumors and 2 had peritoneal tumors, while 6 of the women had pleural tumors and 1 had a peritoneal tumor. Most cases in both sexes occurred in patients in the 50-69 yr age group, and a preponderance of cases were reported from Glasgow and Edinburgh. Ninety-five percent of mesothelioma patients smoked 1-14 g of tobacco/day, while 16% of mesothelioma cases were non-smokers. Ninety-five percent of mesothelioma cases had experienced either definite or probable exposure to asbestos, while 60% of cancer controls had had asbestos exposure, and 30% of noncancer controls had had asbestos exposure. More than twice as many mesothelioma cases reported residential as well as occupational asbestos exposure than did not. Occupational exposure to asbestos in mesothelioma patients was usually incurred in connection with the Scottish shipbuilding industry.

GALLBLADDER CARCINOMA IN THE MEXICAN POPULATION OF THE SOUTHWESTERN UNITED STATES. Bornstein, F. P. (Providence Mem. Hosp., El Paso, Tex.). *Path Microbiol* 35(1-3):189-191, 1970.

The incidence of gallbladder carcinoma in the Mexican population of the El Paso, Texas, area was investigated. In a survey of 4,500 autopsies, there were 94 carcinomas of the gallbladder and bile ducts and 64 carcinomas of the pancreas. In a comparison population from Chicago, there were 23 pancreatic carcinomas and 3 cancers of the gallbladder and ducts. These figures yield age-adjusted incidence rates of 6 cases of gallbladder cancer/100,000 cases in the Mexican population compared to 2.2 cases/100,000 for the non-Mexican population. The incidence rates for the Latin American population show 12 gallbladder cases/100,000 for women and 4 cases/100,000 for men. The high incidence of

gallbladder cancer among Mexican-Americans may be due to the Mexican practice of eating highly spiced foods in a low animal-protein diet.

1172 GASTRIC CARCINOMA IN A FIXED POPULATION: HIROSHIMA AND NAGASAKI. (E.) Yamamoto, T. (Atomic Bomb Casualty Commis. Hiroshima, Japan), H. Kato, K. Ishida, E. Tahara and D. H. McGregor. *Gann* 61(5):473-483, 1970.

The incidence of gastric carcinoma among residents of Hiroshima and Nagasaki, Japan, who had been exposed to nuclear bomb blast-irradiation in 1945 was investigated, and an attempt was made to correlate the degree of radiation-exposure and the subsequent development of cancer of the stomach. Autopsy records from 2,908 cases of carcinoma of the stomach in the exposed population were examined. The prevalence rates of gastric carcinoma in general showed that rates were higher for females in Hiroshima than for females in Nagasaki (prevalences of 9.9 and 5.9% for the 2 cities, resp.). Males showed a prevalence peak around age 50 yr, while prevalence peaks among females occurred around age 40. Seventy-eight percent of fungating lesions were of the papillary tubular type and 37% of the scirrhous type of carcinoma were of the fungating type. More carcinomas were found in the pylorus and fundus areas of the stomach than in other sites (41 and 19% of tumors in the 2 sites, resp.). The frequency of tumors in the fundus was high in subjects under 60 yr and high in the pylorus in subjects over 60 yr. Diffuse carcinomatous proliferation involving the entire stomach was more frequent in cases of scirrhous type carcinoma than in the tubular medullary type carcinoma; tubular medullary type carcinomas were the most common type followed by scirrhous type carcinomas. Metastases were found in the liver, intestinal tract, and pancreas. In general, no significant correlation was found between the prevalence rate of stomach cancer and amount of radiation exposure, except in males in Nagasaki.

1173 THYROID CARCINOMA IN CHILDHOOD: FINAL REPORT ON A 20 YEAR OLD STUDY. (E.) Winship, T. (Child. Hosp., Washington, D.C.) and R. V. Rosvold. *Clin Proc Child Hosp D C* 26(11):327-348, 1970.

The incidence, pathology, and clinical course of 878 cases of childhood thyroid carcinoma collected since 1948 were detailed. Nearly 80% of these cases were reported from the United States, but it was estimated that the case reports comprised less than 1/2 of cases occurring in the United States, and an even smaller fraction of cases occurring throughout the world. The distribution of the cases failed to confirm the hypothesis that thyroid cancer has a high incidence in goiterous areas of the world; highest incidence rates were recorded from Hawaii, Colombia, Israel and Iceland, of which only 2 are goiterous regions. Most recorded cases of thyroid cancer were diagnosed between the yrs 1945-1955 with a peak in 1957 (70 cases diagnosed); thereafter, the number of cases fell off sharply, perhaps reflecting the decline in popularity of radiation therapy given to the heads and necks of

children. A relationship was found between radiation of the head and neck and thyroid cancer; histories of radiation were obtained from 476 patients. Of these, 76% had been treated from 3.5 to nearly 14 yr before the diagnosis of thyroid cancer. Radiation doses ranged from 140-2600 rads. The relationship between radioactive iodine and thyroid cancer was emphasized. The ages of patients in the study for whom complete clinical data was available was 1 wk-14 yr, with the average age being 9.4 yr; 62% of the patients were girls. In 4 instances, thyroid cancer occurred in members of the proband's family. For the most part, presenting symptoms were 1 or more firm painless nodules in the neck; in 9 patients the first evidence of the disease was pulmonary metastases. Seventy-four percent of patients showed metastatic carcinoma in the cervical lymph nodes at the time of first examination. Treatment was usually surgical. Seventy-one percent of the cases of thyroid cancer were of the papillary type, and 17% were of the follicular type. On follow up, it was found that 300 patients survived for 10 yr, 16 survived for 30 yr, and 2 survived for 40 yr.

- 1174 EXPERIENCE WITH 1079 CASES OF CANCER OF THE STOMACH SEEN IN KOREA FROM 1962 TO 1968. (E.) Crane, P. S. (Nashville, Tenn.), S. U. Rhee and D. J. Seel. *Amer J Surg* 120(6):747-751, 1970.

The incidence and pathology of stomach cancer was investigated in a population from Korea; case material included 1,079 cases of stomach cancer admitted to the hospital between 1962 and 1968. The number of cases recorded in this period rose steadily with 87 cases in 1962, 132 in 1964, and 230 in 1968. The stomach cancer patients comprised 1.7% of all patients presenting at the clinic where the study was performed. Seventy percent of the patients were over 45-yr-old, and 53% were over 50-yr-old; the male-female ratio was 3 to 1. The peak age for onset of stomach cancer in males was 52 yr and for females, 42 yr. Sixty-six percent of the sample population was composed of farmers, while 50% of all patients presenting to the hospital were farmers. In 74% of cases, the stomach tumor was located in the pyloric region; 88% of those patients for whom a pathologic diagnosis was made were diagnosed as having adenocarcinoma and anaplastic cancer was found in 10%. A study of the diets of 170 of the patients showed that patients with stomach cancer appeared to have a significantly higher intake of soy bean paste than patients of the same age and sex without stomach cancer. The fact that *Aspergillus flavus* is found in soy bean cakes eaten by Koreans raised the possibility that aflatoxins produced by this mold may have a role in the genesis of stomach cancer in this population.

- 1175 A COMPARISON OF SOME EPIDEMIOLOGICAL ASPECTS OF CERVICAL AND ENDOMETRIAL CARCINOMA. (E.) Modan, B. (Tel Hashomer Govt. Hosp., Ramat Gan, Israel), Z. Sharon, M. Shani and C. Sheba. *Path Microbiol* 35(1-3):192-197, 1970.

The incidence of cancer of the cervix and endometrium in the Jewish population of Israel was investigated. The study group comprised 275 cases of cervical cancer and 388 cases of endometrial cancer; mean annual incidence for the 2 conditions were 4.7 cases of cervical cancer/100,000 population and 6.6 cases of endometrial cancer/100,000. (Although 25 cases were recorded among Arabs, the analyses of the data were performed only on cases recorded among Jews.) For both cervical and endometrial cancer, there are peaks in incidence in the 60-69-yr-old group. While case of cancer of the corpus increased steadily in frequency until the age of 60, the incidence of cervical cancer declined from age 42-52 yr. Forty-four percent of patients with cervical cancer were less than 50 at diagnosis, while 20% of patients with cancer of corpus were less than 50 yr. The rate of cervical cancer was higher among African born Israelis, while the rate of endometrial cancer was higher among European born Israelis. At age 60, African born Israeli had an incidence of cervical cancer of 27%, while at the same age European born Israelis had an incidence of 9%. At age 65, European born Israelis had an incidence of endometrial cancer of 42%, while at the same age, the incidence for African born Israelis was 23%. The excess of cervical cancer among the African-born may be attributable to those born in Morocco, where the ratio of cervical to endometrial cancer approaches 5:1. More women who had been married had cervical cancer, while more single women had endometrial cancer.

- 1176 MALIGNANCIES IN MAINLAND TANZANIA: SQUAMOUS CELL CARCINOMAS. (E.) Anderson, C. (Central Path. Lab., Dar Es Salaam, Tanzania). *Acta Trop* 27(3):208-218, 1970.

The incidence, demographic distribution, and age distribution of squamous cell carcinoma of various sites were investigated in the Tanzanian population. Site distribution of 1527 cases of squamous cell carcinoma showed that only tumors of the skin and of the cervix uteri occurred in sufficient numbers for adequate epidemiological analysis; cancer of the skin was found in 393 males and 256 females, and cancer of the cervix was found in 431 cases. Demographically, the Wayao and Wazaramo tribes had the highest incidences of squamous cell carcinoma of the cervix, showing 7.77 and 4.15 cases/100,000 population, resp. The most common location for carcinoma of the skin was the lower limb (66% of male cases and 67% of female cases). For females, the second common location for skin cancer was the trunk (9% of female cases); and for males, the second most common location was the scalp and neck (11% of male cases). The Wabena and Wagogo tribes had slightly higher incidences of skin cancer than other tribes (2.40 and 2.14 cases/100,000 population, resp.). The age distribution of 115 cases of squamous cell carcinoma of the skin showed a peak in incidence between the ages of 45-50, and a lower peak in incidence between the ages of 60-65.

77 THE EPIDEMIOLOGY OF ORAL AND OROPHARYNGEAL CANCER IN INDIA. (E.) Jussawalla, D. J. *Annals of the Tata Mem. Hosp., Bombay, India. Oto-Rhino-Laryngology* 206:832-839, 1970.

The incidence and mortality of oral and oropharyngeal cancer in India was investigated, and a specific etiological factor identified. Age-adjusted incidence rates for cancer of the buccal cavity and pharynx indicate that the Bombay area has the highest worldwide rates for both males and females (13 and 15 cases/100,000 population, resp.); these rates were markedly higher than rates for Puerto Rico, the nation with the next highest incidence rates (Puerto Rican rates for males and females, resp., were 24 and 9 cases/100,000 population). Incidence rates for cancer of the lip, salivary glands, nasopharynx, buccal mucosa, palate and nasopharynx in Bombay were approximately comparable to rates for other countries; however, females in Bombay appeared to have a slightly higher incidence of lip cancer than males in other countries. Incidence rates for cancer of the tongue and pharynx were higher in Bombay than elsewhere; rates for tongue cancer for males and females in Bombay were 14.6 and 3.3 cases/100,000, compared 7.1 and 2.1 cases/100,000 for males and females in Puerto Rico. Mortality rates for cancer of the buccal cavity and pharynx were higher in Bombay than elsewhere, with Bombay's rate being 2.4 deaths/100,000 population compared with 2.3 deaths/100,000 for Ceylon and 1.3 deaths/100,000 for American Caucasians. Tobacco chewing was identified as an etiological factor in oral and oropharyngeal cancer in India, with 72% of oral and pharyngeal cancer patients being tobacco chewers. Another etiological factor appeared to be abrasion of the back of the tongue by sharp decayed teeth.

78 THE RISING INCIDENCE OF CARCINOMA OF THE PANCREAS: AN EPIDEMIOLOGIC APPRAISAL. Krain, L. S. (Los Angeles, Calif.). *Amer J Roentgenol* 54(5):500-507, 1970.

Environmental and genetic factors in the incidence of cancer of the pancreas were investigated in an examination of mortality rate data for this condition. Age-specific death rates showed that death rates for cancer of the pancreas becomes markedly more frequent after the age of 45 yr and does not level off appreciably before the age of 85 or above; rates per 100,000 population from pancreatic cancer were 8 at the age of 45 yr and 32 at 60 yr. Female death rates from cancer of the pancreas approached male death rates 10 yr after menopause, with female mortality increasing relative to male mortality after the age of 60. The numbers of male and female hospital admissions for pancreatic cancer were 9.6 and 6.4/100,000 population, resp., for Caucasians and 13.0 and 6.0/100,000 population for Negroes. Negro males have the highest incidence of cancer of the pancreas, and Japanese living in America have a higher incidence of the disease than do Japanese living in Japan. The above finding confirms the importance of environmental factors in pancreatic cancer. The observed lack of relationship of the condition to menopausal

or climacteric periods further minimizes a hormonal or genetic linkage for pancreatic cancer and suggests that exogenous factors are more important. Cigarette smokers who consume from 21-39 cigarettes/day were found to have a lower median age of occurrence of cancer of the pancreas than nonsmokers or light smokers. Death rates/100,000 population for smokers are 11 and 19, resp., for females and males aged from 45-65 yr; death rates for nonsmokers in the same age and sex categories are, resp., 6 and 7/100,000 population. An inverse relationship was found between rank order of air pollution in 4 California cities and their incidences of pancreatic cancer; however, differences among cities were insignificant, and it was concluded that air pollution is not as closely related to pancreatic cancer incidence as is cigarette smoking.

1179 CANCER IN IRAN: STATISTICAL REVIEW ON 28,000 CASES. (E.) Habibi, A. (Tadj Pahlavi Cancer Inst., U. Teheran, Iran). *Path Microbiol* 35(1-3):181-183, 1970.

The distribution of cancer of various sites in the population of Iran was investigated in a review of 28,000 cases. Among males, the 3 most frequently occurring types of cancer were cancer of the skin (26% of cases), cancer of the lymph nodes (12% of cases), and cancer of the esophagus (5% of cases). Among females, the most frequently occurring types of cancer were cancer of the cervix (21% of cases), cancer of the skin (16% of cases), and cancer of the breast (13% of cases). Skin cancer was the most common form of malignancy, accounting for 21.7% of total cases. This disease appeared to be causally related to exposure to sunlight, contact with contaminating clothing, and poor personal hygiene; it was more prevalent in the poorer classes of Iranians. Most skin malignancies appeared on the face, head and neck, and most patients with skin cancer were between 50-69 yr-of-age. Cancer of the cervix was the next commonest malignancy in Iran. Most patients were between the ages of 35-54 yr-of-age, and most were from the poorer socioeconomic classes. The frequency of lymphatic cancer was similar in all social classes. Half the cases of lymph node cancer were located in the neck. Hodgkin's disease comprised 40% of the cases of lymphatic cancer. Breast cancer occurred with greatest frequency among women who had not breast-fed children, and was accordingly prevalent among the more leisured classes. Esophageal tumors were more frequent in the middle and lower third of the esophagus; squamous cell carcinoma was very common in connection with esophageal cancer, making up 85% of cases. Cancer of the larynx and lower respiratory tract comprised 5% and 4%, resp., of male cases. Most patients affected with these 2 forms of cancer were between 45-64 yr-old.

1180 NATURAL HISTORY AND TREATMENT OF WILM'S TUMOR: AN ANALYSIS OF 335 CASES OCCURRING IN ENGLAND AND WALES 1962-1966. (E.) Ledlie, E. M. (Dept. Soc. Med., Oxford U., England), L. S. Mynors, G. J. Draper and P. D. Gorbach. *Brit Med J* 4(5729):195-200, 1970.

Clinical features of Wilm's tumor were examined in a survey of 335 cases of this condition. All patients were under the age of 10 yr; there were 184 boys and 151 girls. Peak incidence of tumors was at 18 months of age (70 cases); by 9.5 yr of age, the number of cases had declined to 8. Congenital tumors occurred in 10 children, and congenital defects including duplex kidney and hemihypertrophy were associated with Wilm's tumor in 20 cases. Tumors recurred after nephrectomy in 156 of 232 cases followed after surgery; the 3 yr survival rate for recurrence cases was 12%. Three yr survival for nephrectomized patients was approximately 35%; no patient who did not undergo nephrectomy survived. In some cases, tumors may have been associated with obstetric radiography during the third trimester of pregnancy; latent periods from irradiation to onset of symptoms were from 12-36 months. Pulmonary metastases were noted in 105 cases. Little improvement in survival rate was effected by treatment with actinomycin D.

1181 CERTAIN MORTALITY PATTERNS OF ESOPHAGEAL CANCER IN THE UNITED STATES, 1930-1967.

(E.) Schoenberg, B. S. (Rochester, Minn.), J. C. Bailar, III and J. S. Faumeni, Jr. *J Nat Cancer Inst* 46(1):63-73, 1971.

Mortality rates for cancer of the esophagus were examined for different white and non-white populations in the United States and for different geographic areas. An excess in mortality was found for non-white groups, which included Negro, Chinese and Japanese; mortality rates for Negroes generally exceeded those for Chinese and Japanese. From 1960-1964, average age-adjusted mortality rates/100,000 population for Negro males and females were 9.99 and 2.39, resp., in this period; mortality rates for Chinese men and women were 8.12 and 0, resp., and 6.30 and 0.43, resp., for Japanese men and women. In the same period, mortality rates for the white population were 3.69/100,000 and 0.96/100,000 for males and females, resp. The highest rates of esophageal cancer mortality were recorded from the Northeastern United States, and the lowest rates were recorded from the South. While male whites living in New England had mortality rates of 4.52/100,000 from 1960-1965, whites in the East South Central region at the same period had rates of 2.26/100,000; non-whites in New England over the same period had mortality rates of 14.36/100,000 and non-whites in the East South Central region had a rate of 5.02/100,000 esophageal cancer mortality was correlated with urbanization, cigarette sales, and alcohol sales. Some factor other than smoking or alcohol consumption was presumed to be operating in the urban environment which predisposed its city dwellers (especially non-white city dwellers) to cancer of the esophagus.

1182 PET ASSOCIATION WITH SELECTED HUMAN CANCERS: A HOUSEHOLD QUESTIONNAIRE SURVEY.

(E.) Hanes, B. (Dept. Hlth. Sci., San Fernando Valley St. Coll., Northridge, Cal.), M. B. Gardner,

C. G. Loosli, G. Heidebreder, B. Kogan, H. Marylander and R. J. Huebner. *J Nat Cancer Inst* 45(6):1155-1162, 1970.

The hypothesis that persons with specific types of cancer known to be associated with C-type viruses in cats might have more exposure to domestic cats than healthy control groups was investigated. A questionnaire survey was conducted among households of victims of leukemia, lymphoma, or sarcoma, and among control households; 530 "index" cancer households and 1,042 control households were included in the survey. It was found that the average yr of cat ownership was 8.0 in lymphoma households compared to 4.1 yr in controls. This excess was probably due to an increase in the number of yr during which cats were kept in lymphoma households rather than to a greater number of lymphoma households with cats. This apparent excess of lymphoma cases in catkeeping households was accounted for by failure to match controls with index households for duration of residence at the same address. No difference was found between index and control households in the numbers of yr that cats had been owned, the number of index and control households with cats, the average number of cats owned, and the percentage of male cats (which are more susceptible to feline lymphoma) were not of statistical significance for incidence of cancer. Nor was there any strong evidence for a correlation between cause of cat death (e.g. malignancy, cardiac trouble) and incidence of cancer in owners' households. No differences were found between control and index households in the patterns of ownership of dogs or parakeets. Furthermore, 70-80% of family members with cancer did not own cats, which makes it seem unlikely that a causal connection exists between cat ownership and human malignant disease.

1183 THE ENVIRONMENTAL DISTRIBUTION OF CANINE RESPIRATORY TRACT NEOPLASMS. (E.) Reif,

J. S. (Sch. Vetr. Med., U. Pennsylvania, Philadelphia) and D. Cohen. *Arch Environ Hlth* 22(1):136-140, 1970.

The possibility of a relationship between canine respiratory tract neoplasia and residence in an urban environment involving exposure to polluted air was explored. Case records of all dogs with histologically proven primary neoplasia of the lungs and bronchi, nasal passages and paranasal sinuses, tonsils, stomach and intestine seen in a veterinary hospital from 1952-1969 were reviewed. The case material included 51 dogs with lung and bronchial carcinoma, 57 with carcinoma of the nasal passages and paranasal sinuses, and 57 with carcinoma of the tonsils. A group of 74 dogs with neoplasms of the stomach and intestine served as controls. The mean ages for dogs with neoplasms of the 4 sites studied showed clustering around the age of 10.5 yr. Forty-seven percent of cases of carcinoma of the lungs and bronchi, and a similar proportion of cases of carcinoma of the nasal passages and paranasal sinuses were composed of dogs from urban environments. However, 73.7% of cases of carcinoma of the tonsils were composed of dogs from urban environments. Sixty percent of all dogs

re from urban environments, and 47% of dogs with gastrointestinal carcinomas were from urban environments. Most of the dogs with carcinoma of the asils were mongrels, possibly reflecting the relative rarity of purebred dogs residing in urban environments.

34 EPIDEMIOLOGY, CLINICAL AND RADIOLOGICAL FEATURES OF PRIMARY LUNG CANCER. A REPORT ON 120 CASES DETECTED AT THE ANTITUBERCULOSIS CONSORTIUM IN ALESSANDRIA. (It.) Calamari, F. (Provincial Antituberculosis Consortium Alessandria, Italy) and L. Prigione. *Riv Ist Vaccinogeno* 20(3): 3-24, 1970.

The detection of 120 cases of primary lung cancer during the yr 1968-1969 in the district of Alessandria (southern Italy) revealed an incidence of 4 per 100,000 inhabitants and an index of 24.7 per 100,000 inhabitants within the population above yr-of-age. When focused on the male population between 35 and 64 yr-of-age, this index increased to 59.9 per 100,000 inhabitants. The incidence of primary lung cancer in the urban area of Alessandria appeared to be higher than in any other part of Italy, probably due to its chromate manufacturing industries; this index appeared very high within the towns of Acqui Terme and Ovada with a prevalent agricultural economy but with a large part of its population involved in the industry of Alessandria. The contribution of air pollution, occupational exposure (chromium, asbestos, Ni, As, iron des and radioactive metals) and cigarette smoking to the increase of lung cancer incidence is re-evaluated.

5 SOME STATISTICAL DATA ON THE CARCINOGENIC HAZARDS FOR WORKERS INVOLVED IN THE PRODUCTION OF NICKEL FROM OXIDIZED ORES. (Rus.) Shabynina, A. V. (Inst. Work Hyg. and Occupational Health, Sverdlovsk, USSR) and N. K. Shabynina. *Gig Prof Zabol* 14(11):10-13, 1970.

The incidence of cancer among workers from a nickel concentration and melting plant in the Urals was compared to that of the city population. Data were obtained from records covering the period from 1955-1967. Mortality from lung cancer was 2.8 times higher among nickel workers than among the urban population; lung cancer among the plant workers was limited only to males above the age of 40 yr, who spent an average of 13 yr at this activity. Within the plant the highest cancer incidence, 2.1 times the cancer incidence among the urban population, was found in the roaster section (reduction of nickel) due to exposure to nickel sulfide and nickel oxide-containing dusts and in the cobalt section due to cobalt and arsenic exposure (1.4 times the urban population). The incidence of mesosarcoma among workers of the 40-50 yr group was 6.2 times that of the city population.

1186 FATAL TESTIS TUMORS IN THE FEDERAL REPUBLIC ARMY. (Ger.) Altwein, J. E. (U. B. Mairrose and K. Wegner. Mainz, Germany) *Med Monatsschr* 24(11):489-493, 1970.

An evaluation of the mortality rate among the soldiers of the Federal Republic due to testicular tumors is presented. Out of 70 soldiers in whom such tumors were discovered between 1956 and 1969, 66 were diagnosed as such. The tumors were classified under the headings of: seminoma (SE), embryonal carcinoma (EC), and teratocarcinoma (TC). The distribution of the 66 cases was: 39 with TC, 17 with SE, and 5 with EC. The remaining 5 cases appeared to have a retroperitoneal tumor with clinically inconspicuous testicular involvement which was proven histologically. The total mortality rate for testicular tumors amounted to 1.6/100,000 soldiers. The peak for the age distribution of death from this cause was 21 years. No familial connection was revealed in the incidence of this disease, and the case histories did not reveal any early virus infection such as mumps as a causal effect.

1187 AGE AT FIRST BIRTH AND BREAST CANCER RISK. (E.) MacMahon, B. (Dept. Epid., Harvard Sch. Pub. Hlth., Boston), P. Cole, C. R. Lowe, A. P. Mirra, B. Ravhihar, E. J. Salber, V. G. Valaoras, and S. Yuasa. *Bull WHO* 43(2):209-221, 1970.

The association between age, parity, and risk of developing breast cancer was investigated in a global study of more than 4000 cases of breast cancer. Study populations were examined in 7 test centers: Boston, Glamorgan (Wales), Athens, Slovenia (Yugoslavia), Sao Paulo, Taipei, and Tokyo. Estimated breast cancer risks for women of parity 5 or more were from 40-60% of risks for the nulliparous. In all 7 centers, risk of developing breast cancer increased with the age at which a woman had her first child; women having the first child under the age of 20 yr had only 33% of the risk of women having their first child at age 35 yr or more. Risks for women having their first child at from 30-34 yr of age were similar to risks for nonparous women. Generally, risk of breast cancer increased linearly with increasing age at first birth till 30 yr; for women having their births when under 20 yr old, the risk of breast cancer decreased as age at first birth decreased. The association of breast cancer risk with age at first birth was not a simple reflection of the low parity of breast cancer patients. Births after the first had relatively little effect on breast cancer risk.

1188 NEOPLASMS OF CHILDHOOD AFFECTING THE HEAD AND NECK. (E.) Smoler, J. (Nat'l. Med. Ctr., I.M.S.S., Mexico City, Mexico), G. Velazquez, G. Vivar and S. Levy-Pinto. *Oto-Rhino-Laryngology* 206:863-866, 1970.

The incidence, pathology, and clinical course of neoplasms of the head and neck affecting children were reviewed. Prominent among these tumors is Burkitt's lymphoma, a malignant neoplasm of primarily undifferentiated lymphoreticular cells. Burkitt's lymphoma in African cases often appears as a jaw tumor, while abdominal tumors are also seen. The mean age of 21 patients with Burkitt's lymphoma was 10.6 in 1 study. Twelve of 18 American Burkitt patients presented bone marrow involvement, while only 2 of 33 African patients showed marrow involvement. A herpes-like virus has been found in 100% of clinically proven African Burkitt's lymphoma cases in 1 study. Benign tumors of the head and neck observed in a pediatric hospital (149 total cases) included 39 hemangiomas, 36 papillomas, 26 lymphangiomas, 17 ranula, and 10 juvenile angiofibromas. All benign tumors were treated with surgery with good results. Of 78 malignant head and neck tumors observed at the same children's hospital, 30 were reticuloendothelioses, 18 were Hodgkin's disease, 8 were lymphoblastic lymphoma, 5 were reticulosarcoma, and 4 were rhabdomyosarcoma. All cases of metastasizing malignancies which were treated with radiotherapy and/or chemotherapy proved fatal.

- 1189 BACTERIA AND AETIOLOGY OF CANCER OF THE LARGE BOWEL. (E.) Hill, M. J. (St. Mary's Hosp. Med. Sch., London, England), B. S. Drasar, V. Aries, J. S. Crowther, G. Hawksworth and R. E. O. Williams. *Lancet* 1(7690):95-100, 1971.

The association between high incidences of carcinoma of the colon and fecal bacteria and steroid content was investigated. Feces from subjects in 6 countries were examined for the presence of bacterial flora and steroids; the populations studied were from England, Scotland, the United States, India, Uganda, and Japan. Feces from Britain and the United States, where the incidence of colon cancer is high, had larger amounts of *Bacteroides* and smaller amounts of enterococci than feces from India, Uganda, or Japan. Mean \log_{10} colonies/g wet wt of fecal matter from the British Isles and United States were 9.7-9.8 for *Bacteroides* spp., while counts for this bacterium from Uganda and India were 8.2 and 9.2, resp. Mean \log_{10} colonies/g wet wt for enterococci for fecal samples from Uganda, India, and Japan ranged from 8.2-9.4, while counts for enterococci from England, Scotland and the United States ranged from 5.0-5.9. Feces from peoples in Western countries contained higher concentrations of steroids than those from African and Eastern countries, and the steroids were more degraded in the former groups. The results are consistent with the hypothesis that the intestinal bacteria may be related to cancer of the colon.

- 196 ENZYMATIC ACTIVITIES OF TUMORS OF THE NERVOUS SYSTEM *IN VIVO* AND *IN VITRO*. (E.) Brunner, M. L. (U. Utah Coll. Med., Salt Lake City). *Arch Path* 91(2):148-155, 1971.
- Istochemical differences in nicotinamide adenine dinucleotide tetrazolium reductase (NADH reductase), lactate dehydrogenase (LDH), glucose-6-phosphate dehydrogenase (G6PDH) and acid phosphatases between sections of nervous system tumors (astrocytoma, glioblastoma, ependymoma, meningioma and schwannoma) and cells of the same tumors grown *in vitro* were investigated by appropriate staining methods. In general, the enzymes studied underwent a transient decrease in activity during the first week of *in vitro* growth, but then returned to the same levels as in the parent tumor. LDH activity stabilized at 80% of the levels found in the parent tumor in glioblastoma cultures and at 50% of the parent tumor levels in choroid plexus papilloma cultures. G6PDH activity increased almost 2-fold in glioblastoma cultures and 5-fold in schwannoma cultures compared to the parent tumors. Most cultures showed some mesenchymal activity. With all cultures developed moderate numbers of large, bizarrely-shaped, multinucleated cells lying about the periphery of outgrowth; these cells showed faint NADH reductase, LDH, G6PDH and acid phosphatase activities.
- 97 LYMPHOCYTE SENSITISATION: AN *IN VITRO* TEST FOR CANCER? (E.) Field, E. J. (Newcastle Gen. Hosp., England) and E. A. Caspary. *Lancet* 7687):1337-1341, 1970.
- Sensitization of blood lymphocytes from patients with malignant disease to a basic protein, encephalogenetic factor (EF) and to a basic protein derived from the human sciatic nerve (SNBP) was observed. The presence of these proteins as antigens, guinea pig macrophages migrate more slowly in cultures of sensitized human lymphocytes. Tests for lymphocyte sensitization were performed on 38 healthy subjects and on 56 patients with malignancies including carcinoma of the cervix, bronchus, kidney, breast and bladder. Among the controls, macrophage migration was inhibited by 0.9-3.6%. All 56 cancer patients, with or without signs of non-metastatic nervous involvement, showed marked inhibition of macrophage migration with EF (8.2-29.9%) and SNBP (7.7-30.4%). Patients harboring an untreated carcinoma did not react differently from patients who had undergone successful cancer therapy. The type of neoplasm did not affect the reactions. Tests on patients with benign neoplasms showed normal values for the sensitivity to the protein antigens.
- 98 INFLUENCE OF THE LETHAL YELLOW (AY) GENE ON DEVELOPMENT OF RETICULAR NEOPLASMS. (E.) Dinger, M. K. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Nat Cancer Inst* 45(6):1205-1210, 1970.
- The influence of the lethal yellow gene (AY) on the development of reticular tumors was investigated. A strain of "yellow" mice, (YBR x AKR)_{F1} hybrids, was

developed in which the presence of the gene increased susceptibility to spontaneous reticular neoplasms. Mice having the (AYa) gene developed reticular tumors at earlier ages (21-22 months) than did mice having the (aa) gene (26-28 months). The lethal yellow gene also appeared to increase susceptibility to spontaneous hepatomas (97-100% vs 51-63%) and to spontaneous pulmonary tumors (at 20-22 months vs 27-30 months). The "yellow" hybrid mice also developed unusual liver tumors, interstitial cell tumors in the testis of males, and thymic lesions. "Yellow" hybrids showed increased body size compared to mice not bearing the AY gene; differences of 18 g at 6 and 12 months of age between males carrying the AYa and aa genes were recorded, and differences of 24 and 22 g at 6 and 12 months of age were recorded for females with and without the lethal yellow gene.

- 1199 POSTCASTRATIONAL ADRENAL TUMORS IN TWO STRAINS OF MICE: MORPHOLOGIC, HISTOCHEMICAL, AND CHROMATOGRAPHIC STUDIES. (E.) Krishna Murthy, A. S. (Child. Hosp. Med. Ctr., Boston, Mass.), M. A. Brezak and A. G. Baez. *J Nat Cancer Inst* 45(6):1211-1222, 1970.

Adrenal tumors which developed in strain DBA and strain CE mice of both sexes following castration were compared morphologically. DBA mice were examined on autopsy 6 and 12 months after castration, while CE mice were examined 12 months after castration. DBA adrenal tumors showed nodular hyperplasias and adenomas with low levels of succinate dehydrogenase activity and high levels of 3 β -hydroxysteroid dehydrogenase activity. The DBA tumors contained estrone, and uteri were progressively stimulated. Adrenal cortical tumors developed by CE mice were larger than those developed by DBA mice; tumors in CE mice also more pleomorphic histologically. CE tumors showed intense succinate dehydrogenase activity and variable 3 β -hydroxysteroid dehydrogenase activity. Estrone was also present in extracts from CE tumors, and uteri were stimulated. In both strains of mouse, pituitary gonadotropins were increased at 6 and 12 months. Androgen was evidently not produced in the seminal vesicles of either strain.

- 1200 COMPARISON OF METHYL-LABELED tRNA IN A NEOPLASTIC CELL LINE WITH A PAIRED NON-NEOPLASTIC CONTROL. (E.) Quinn, C. E. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), R. Gantt and V. J. Evans. *Exp Molec Path* 13(2):231-241, 1970.

Methylation of tRNA was compared in intact cells from a non-neoplastic mouse embryo cell line grown in NCTC 135 medium supplemented with 10% fetal calf serum and a neoplastic cell line derived from the non-neoplastic cell line by changing the medium to one with 10% horse serum. By growing the non-neoplastic mouse cell line in ³H-methylmethionine and the neoplastic line in ¹⁴C-methylmethionine, it was possible to simultaneously extract, isolate and chromatograph the tRNA from the 2 different systems. Comparison of reversed-phase chromatography profiles of methylated tRNA indicated a small chromatographic heterogeneity, but the differences appeared to be quantitative rather than qualitative. Because of the minimal differences

in the experimental system of the two cell lines (the neoplastic line being derived from the non-neoplastic one) and the simultaneous isolation of tRNA, the differences in methylation appear to be real and may bear some relationship to malignancy.

- 1201 LEUKAEMIC TRANSFORMATION OF ENGRAFTED HUMAN MARROW CELLS *IN VIVO*. (E.) Fialkow, P. J. (Dept. Med. Genet., U. Washington, Seattle), E. D. Thomas, J. I. Bryant and P. E. Neiman. *Lancet* 1(7693):251-255, 1970.

A case is reported of a 16-yr-old girl with acute lymphoblastic leukemia in whom there was a leukemic transformation of engrafted marrow cells donated by her brother. The patient was given a 1000 rads midline tissue dose of whole-body irradiation on the day before she was given 14×10^9 nucleated marrow cells from her HL-A matched sib. Two wk later, the patient's white blood cell count reached a minimum of 20 cells/mm³, thereafter rising to 1500 cells/mm³ on day 19. Apparently, the marrow cell graft had been successful, and only donor-type XY cells were found in uncultured marrow from the patient. Sixty-two days after the marrow graft, the patient's leukemia recurred, and cytogenetic studies showed that the leukemia had affected the previously normal XY graft cells. It was suggested that the transformation of the normal XY cells was caused by the activation of a leukemogenic agent, possibly viral, in the susceptible cells. Alternatively, such an agent may have been transferred to the donor cells from the leukemic cells of the recipient.

- 1202 STUDIES OF DNA-INDUCED HERITABLE ALTERATION OF MAMMALIAN CELLS. (E.) Borenfreund, E. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.), Y. Honda, M. Steinglass and A. Bendich. *J Exp Med* 132(6):1071-1089, 1970.

Normal Chinese hamster cells (CH) were exposed to mouse Ehrlich ascites tumor cells (EA) to study the interactions resulting from co-culture. Several hr after co-culture was begun, adhesions and bridges between the 2 cell types were seen. When immunofluorescent techniques were applied to co-cultures of CH and EA, the intercellular connections were seen to contain mouse antigen but not CH antigen. An occasional transfer of ³H-thymidine-labeled DNA from EA to CH was observed by radioautographs. After 10 wk of subculturing, a new cell type with the atypical immunofluorescence reaction of control preparations of EA was observed. Karyotype analysis revealed 22 or 23 CH chromosomes in these cells; the subcultures were stable for 1 yr. Some of the clones induced transplantable tumors in the cheek pouches of cortisone-treated weanling Syrian hamsters. Incubation of CH with EA-DNA resulted in the acquisition of the same antigenic properties as EA by the CH.

- 1203 MESSENGER RNA IN HeLa CELLS: AN INVESTIGATION OF FREE AND POLYRIBOSOME-BOUND CYTOPLASMIC MESSENGER RIBONUCLEOPROTEIN PARTICLES BY KINETIC LABELLING AND ELECTRON MICROSCOPY. (E.)

Spohr, G. (Swiss Inst. Res. Exp. Cancer, Lausanne), N. Granboulan, C. Morel and K. Scherrer. *Europ J Biochem* 17(2):296-318, 1970.

Ribosomal RNA synthesis in HeLa cells was inhibited (actinomycin D, 0.05 µg/ml), and cytoplasmic messenger RNA (mRNA) and messenger-like (mlRNA) were investigated. Non-ribosomal RNA (6-7 S) of the cytoplasm existed in the form of ribonucleoprotein complexes pre-existing in the cell and were stable to cell lysis and isolation procedures. mRNA was contained in a mRNA-protein complex associated with ribosomes (density 1.6) and was released by EDTA treatment (density 1.40-1.48). The free mlRNA of the cytoplasm and the mlRNA-protein particles showed the same sedimentation characteristics as mRNA. The kinetics of synthesis and decay of ribonucleoprotein complexes of mlRNA and polyribosome-bound mRNA were followed by labeled uridine incorporation. After 30 min of incubation, free mlRNA-protein was labeled almost exclusively; subsequently, polyribosome-bound label appeared and after 4 hr both mRNA-protein and free mlRNA-protein were equally labeled. Decay was monitored by adding 5 µg actinomycin D to incubation mixtures after 6 hr of labeling; the same rate of decay was observed in both fractions, indicating that the mlRNA in free particles did not represent a precursor of polysome-bound mRNA, or the high dose of actinomycin D may have inhibited any equilibrium which exists between the 2 RNAs. Electron microscopy revealed small, rounded, cytoplasmic particles ranging 100-200 Å in diameter, which may correspond to the mRNA-protein complex.

- 1204 UPTAKE OF TRANSFER RIBONUCLEIC ACID BY NORMAL AND LEUKEMIC CELLS. (E.) Herrera, F. (Natl. Cancer Ctr., Natl. Inst. Hlth., Bethesda, Md.), R. H. Adamson and R. C. Gallo. *Proc Nat Acad Sci* 67(4):1943-1950, 1970.

Uptake of tRNA into mammalian cells was demonstrated in the murine leukemia, L1210, and in a human lymphoblast (NC037) cell lines. The rate of uptake of tRNA in fresh, human lymphocytes was extremely rapid with uptake being proportional to tRNA concentration up to 50 µg/ml, and plateau levels were reached by 500 µg/ml. Similar kinetics of tRNA uptake were noted in murine leukemia cell line. The percentage of L1210 cells stained with nigrosine dye was 2% in both untreated cells and cells incubated with *E. coli* tRNA. Median survival time of mice inoculated with control and tRNA-treated L1210 leukemic cells did not differ. Thirty to 70% of cells incubated with ¹⁴C-tRNA were labeled during 2 min of incubation, which resulted in vesicle formation characteristic of pinocytosis; radioactivity was present in all subcellular fractions after 5 min of incubation with the nucleus containing 25-60% of the counts. *E coli* tRNA recovered from L1210 cells accepted leucine and could still be methylated, indicating that mammalian cells can take up exogenous tRNA and that an appreciable percentage may remain functional for at least 1 hr. It is possible that tRNA may exert regulatory functions in cell differentiation which may be clarified by experiments based on a nonphysiological input of foreign tRNA.

- 1205 ESTROGEN-INDUCED VARIATION OF LYSINE TRANSFER RIBONUCLEIC ACID ISOACCEPTORS IN CHICKEN LIVER. (E.) Busby, W. F., Jr. (Worcester Found. Exp. Biol., Shrewsbury, Mass.) and P. Hele. *Biochem Biophys Acta* 224(2):413-422, 1970.

The effect of diethylstilbestrol on lysyl-transfer RNA isoacceptors was studied in chicken liver. Young (10-14 wk) chickens were given i.m. injections of diethylstilbestrol (5 mg/100 g body wt) and lysyl-transfer RNA was assayed in the liver by a pH5 precipitation procedure. Prior to treatment with diethylstilbestrol, it was found that transfer RNA produced by laying hens' livers contained 25% more lysyl-transfer RNA than did RNA produced by the livers of cocks or immature hens. The amount of lysyl-transfer RNA in livers of immature birds was 1.49-1.76 nmoles/mg transfer RNA, while the amount of lysyl-transfer RNA in the livers of laying hens was 2.03-2.08 nmoles/mg transfer RNA. Formation of lysyl-transfer RNA in time was higher in diethylstilbestrol-treated birds than in controls; after 5 min of incubation, livers of treated birds produced 48 pmoles of ^{14}C -labeled lysyl-transfer RNA/assay, while controls produced 40 pmoles of lysyl-transfer RNA in the same time. Sixty-five hr after treatment with diethylstilbestrol, lysyl-transfer RNA of treated birds was increased by about 25% over that of controls; the increase was independent of the sex of the bird. Increased lysyl-transfer RNA was recorded for treated birds whether the synthetase preparation was made from control or from diethylstilbestrol-treated chickens. In transfer RNA preparations from diethylstilbestrol-treated chickens, an 18.7% increase in seryl-transfer RNA, and a 9.4% increase in arginyl-transfer RNA were noted. Two species of lysyl-transfer RNA were discovered in control and diethylstilbestrol-treated birds on co-chromatography on methylated albumin-kieselguhr columns. Treated chicken livers contained a marked increase in 1 of these species of lysyl-transfer RNA relative to the other species.

- 1206 THE SÉZARY SYNDROME. CYTOGENETIC STUDIES AND IDENTIFICATION OF THE SÉZARY CELL AS AN ABNORMAL LYMPHOCYTE. (E.) Crossen, P. E. (Dept. Med. Res., Kanematsu Mem. Inst., Sydney Hosp., Australia), J. E. Mellor, A. G. Finley, R. B. M. Ravich, P. C. Vincent and F. W. Gunz. *Amer J Med* 50(1):24-34, 1970.

A case of Sézary syndrome exhibited abnormal leukocytes in the blood over 4 yr of observation. The patient was a 56-yr-old woman who presented with an indolent, intensely pruritic erythroderma accompanied by local scaling of the skin and loss of body hair. Her blood contained moderate numbers of atypical lymphoid cells (2000-5000 cells/mm³) characteristic of the Sézary syndrome. The skin lesions were thought to be prelymphomatous in character, but no systemic changes of lymphoma developed. Cultures of leukocytes were incubated with phytohemagglutinin (PHA), whereupon they demonstrated highly active RNA and DNA synthesis and subsequent cell division. Three cell lines were discovered, with modes of 76, 46, and 98-100 chromosomes. In PHA-

stimulated cultures, the 7-76 chromosome cells were most common, accounting for 10 and 32 cell types, resp., as opposed to 1-7 cells having other chromosome numbers. The abnormal Sézary cells were thought to belong to the lymphoid series and to be potentially neoplastic. The Sézary syndrome was thought to be transformed to a true lymphoma condition upon breakdown of control mechanisms regulating lymphocyte numbers.

- 1207 SUPPRESSION OF MAMMARY HYPERPLASTIC NODULE FORMATION AND PITUITARY PROLACTIN SECRETION IN MICE INDUCED BY ERGOCORNINE OR 2-BROMO- α -ERGOCRYPTINE. (E.) Yanai, R. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan) and H. Nagasawa. *J Nat Cancer Inst* 45(6):1105-1112, 1970.

The effect of treatment with ergocornine or with 2-bromo- α -ergocryptine (CB-154) on the development of mammary hyperplastic nodules and on pituitary prolactin secretion was investigated in female mice. Mice were given daily s.c. injections of 0.2 mg ergocornine methanesulfonate or 0.2 mg CB-154 for 20-23 days or for 40-43 days. The wt of the anterior pituitary and the ovarian wt were significantly decreased in mice given CB-154 and in those given ergocornine for both dose periods. Mice given CB-154 for 20 days developed 23% as many nodules as controls; mice given ergocornine for 29 days developed 39% fewer nodules than controls. Mice treated for 40 days with ergocornine had only 20% of the number of nodules developed by controls, and mice given CB-154 for 40 days developed 8% as many nodules as controls. The average size of nodules in mice given CB-154 was 0.45 mm, while the average size of nodules in controls was 0.67 mm; mice given ergocornine developed nodules which averaged 0.49 mm in size. Numbers of regressed nodules were greater in treated animals than in controls for both dose periods, with ergocornine-treated mice showing 3.6 regressed nodules at 40 days, and CB-154-treated mice showing 2.0 regressed nodules, compared to 0.5 regressed nodules in controls. Lobuloalveolar development was limited in the mammary glands of treated animals, while controls showed moderately developed lobuloalveolar systems. Anterior pituitary prolactin secretion was decreased by the ergot alkaloids to 54-60% of control values, with decreases being more pronounced in the 40-day treatment group.

- 1208 EPIDERMAL CHALONE AND CELL PROLIFERATION IN A TRANSPLANTABLE SQUAMOUS CELL CARCINOMA IN HAMSTERS: II. *IN VITRO* RESULTS. (E.) Laurence, K. R. (Mitosis Res. Lab., Birkbeck Coll., U. London, England) and K. Elgjo. *Virchow Arch Zellpath* 7(1):8-15, 1971.

Extracts of a keratinizing transplantable hamster tumor were tested for their content of epidermal chalone, using normal mouse ear cultures with Colcemid as a test system. A 67% depression of the mitotic rate of mouse ear epidermis was found with tumor extract compared to controls; a 45% depression in mitosis was observed with epidermal chalone from pig skin. The pig skin preparation also inhibited mito-

sis in mouse ear sebaceous glands, but extracts of hamster tumor did not. The mitotic rate of tumor tissue itself was not affected by skin or liver extracts with or without the addition of adrenalin and hydrocortisone. Possible reasons for the lack of response of the hamster epithelial tumor to epidermal chalone *in vitro* may be altered permeability characteristics of the tumor cell, or it may be that this tumor is well-differentiated and the growth fraction so small that changes were not detectable by the methods used.

- 1209 AN ELECTRON MICROSCOPIC STUDY OF METAPLASIA OF THE RAT TRACHEAL EPITHELIUM IN VITAMIN A DEFICIENCY. (E.) Wong, Y. C. (Fac. Med. U. Western Ontario, London, Canada) and R. C. Buck. *Lab Invest* 24(1):55-66, 1971.

The morphological development of metaplasia of the tracheal epithelium of rats fed a vitamin A-deficient diet was followed over a 22 wk period by electron microscopy. Differentiated ciliated and goblet cells decreased in number and lost the highly specific features found in normal cells (cilia, mucus granules, and microvilli). Hyperplastic nests of basal cells appeared to be the first evidence of metaplasia, and these clusters spread with desquamation of the surface epithelium. The hyperplastic cells differentiated into flatter cuboidal cells near the surface (squamous cells) which progressively showed an increase in desmosomes, keratohyaline granules, keratin filaments, and membrane-coating granules. The boundary between nonmetaplastic and metaplastic epithelium was abrupt with desmosomes between the 2 types of epithelium. Metaplastic transformation of the epithelium apparently does not involve differentiated cells but is a result of differentiation of the generative cell in a new direction.

- 1210 REVERSAL OF MALIGNANT TRANSFORMATION BY TUMOR DNA. (E.) Halpern, B. C. (Dept. Chem, U. California, Los Angeles), R. M. Halpern, S. Q. Chaney and R. A. Smith. *Proc Nat Acad Sci* 67(4):1827-1833, 1970.

The *in vivo* infectivity of Walker-256 carcinosarcomas cultured with DNA prepared from the same tumor was investigated. Growth in tissue culture medium of Walker carcinosarcomas with tumor cell DNA did not affect the *in vitro* growth of tumors. However, tumor cells cultured with DNA exhibited a reduced capacity to induce malignant tumors when injected into rats. Female rats were given s.c. injections of 10^5 tumor cells grown in culture with tumor cell DNA; controls were injected with tumor cells of the same type which had not been treated with DNA. Thirty days after injection, 3 of 10 rats given tumor cells grown with DNA for 48 hr were dead with neoplasms, while 8 of 10 rats given untreated tumor cells were dead with tumors. At 30 days, 7/10 of the rats injected with untreated cells cultured for 72 hr had developed tumors, while only 1 of 10 rats given cells cultured with DNA for 72 hr had developed neoplasms. Coincident with the reduced virulence of DNA-treated tumor cells was a decrease in

transfer RNA methylase activity in DNA-treated cells. After a 48-hr exposure to DNA, cells showed a specific transfer RNA methylase activity of 179 pmoles of ^{14}C incorporated/mg protein in 45 min, while untreated cells showed a specific transfer RNA methylase activity of 365. When DNA was removed from the growth medium, the virulence of cells was fully restored, and the inhibition of transfer RNA methylase disappeared.

- 1211 VILLOUS TUMOURS OF THE RECTUM ASSOCIATED WITH SEVERE FLUID AND ELECTROLYTE DISTURBANCE. (E.) Lee, R. O. (Northampton Gen. Hosp., England) and D. Keown. *Brit J Surg* 57(3):197-201, 1970.

Electrolyte disturbance leading to renal failure and associated with villous tumors of the rectum is described in 2 case reports, a female aged 74 yr and a male aged 77 yr. Comparison of the concentrations of sodium and potassium in the blood and rectal fluid from the 2 patients showed that, while sodium levels were similar in the 2 cases, potassium concentrations were 10-20 times higher in one case than in the other. The ratio of sodium to potassium lost in rectal fluid in the 2 cases was 3-4 : 1. It appeared that electrolyte loss associated with the adenomas was general and not limited to loss of potassium.

- 1212 NATURAL EVOLUTION AND PATHOLOGICAL ALTERATIONS OF LYMPHOID CELL PROTEINS: ELECTROPHORETIC PATTERNS OF SOLUBLE AND INSOLUBLE COMPONENTS. (E.) Mobarak, M. A. (U. Pennsylvania Sch. Med., Philadelphia) and J. I. Brody. *Clin Chim Acta* 30(3):635-643, 1970.

The electrophoretic patterns of cellular proteins of various lymphoid organs were investigated, and compared with those of lymphocytes from a patient with chronic lymphocytic leukemia. Four prealbumins were detected in agar gel electrophoresis of normal human lymph node cell extract; most proteins were located in the γ -globulin electrophoretic zone. In lymphocytes from the patient with chronic lymphocytic leukemia, the fastest prealbumin band had 2 anodic branches which gave this zone a semilunar appearance. Most of the protein was located at a peak of m_r 1.43 and appeared as a dense, broad, ill-defined band with striated and unequal vertical margins, the anodal being shorter than the cathodal border. The γ -globulin region was diffuse with ill-defined margins. No differences were noted between the electrophoretic appearances of normal thymus from subjects aged from neonate to 6 months, pre- and post-adolescent normal tonsil, and pre- and post-senescent normal lymph node extracts. When electrophoretic studies were performed on water-insoluble lymphocyte proteins, using urea/formate starch gel, it was found that thymus extracts from subjects of age range 6-24 months showed the smallest number of bands with electrophoretic mobilities comparable to those of serum albumin. Benign thymoma showed an electrophoretic pattern similar to that of normal thymus from infants aged 2-6 months. Giant follicular lymphoma showed a

faint fast-moving band. Extracts from chronic lymphocytic leukemia and from Hodgkin's paraganuloma lymph nodes were similar, with broad ill-defined bands covering both the albumin and prealbumin areas. The major protein component of residues from patients with lymphocytic lymphoma was a broad, ill-defined band adjacent to the cathodal margin of the application slot, in addition to 3 narrow bands in the prealbumin region.

1213 CLINICAL AND PATHOLOGICAL CORRELATION OF NONPIGMENTED TUMORS OF THE CONJUNCTIVA AND PINGUECULAS AMONG AFRICANS. (E.) Ticho, U. (Hadassah Med. Ctr., Jerusalem, Israel) and I. Ben-Sira. *Amer J Ophthalmol* 70(5):757-763, 1970.

The histopathological appearance of nonpigmented tumors of the conjunctiva was observed in 103 African patients. The case material comprised 80 males and 23 females presenting with 1 of 3 types of lesion: pingueculas, elevated glistening white lesions surrounded by pigment, and fleshy protruding lesions of an invasive nature. The pingueculas (25 patients) presented a localized whitish-yellow swelling without keratin covering and with deeply placed blood vessels. Only stromal changes were manifested histologically, consisting of degeneration of the elastic fibers and hyalinization of the connective tissues. The elevated glistening lesions (70 cases) appeared to have originated from pingueculas, the glistening aspect was due to a keratin covering of the lesion. Deeply placed blood vessels were present. The epithelium showed various stages of dyskeratosis, ranging from simple epidermalization to intraepithelial cancer *in situ*. The stroma in this group were not invaded, but showed hyaline and elastic degenerative changes marking pinguecula. Fleshy protruding lesions (8 cases) were papillomatous to cauliflower in shape. Tumors invaded the cornea or sclera. Histopathologically, these lesions showed squamous cell carcinoma with invasion; in 5 cases, epidermalization and other dyskeratotic changes characteristic of other lesion types were seen.

1214 FACTORS CONTROLLING THE GROWTH OF THE YOSHIDA ASCITES TUMOR IN THE UTERUS OF THE RAT. (E.) Lions, J. (Dept. Vetr. Clin. Stud., U. Cambridge, England). *Brit J Exp Path* 51(5):453-463, 1970.

The effect of hormonal status on the growth of transplanted Yoshida ascites sarcomas in the uterus of rats was investigated. Female rats were divided into experimental groups, including intact rats with normal estrous cycles, ovariectomized rats, pseudopregnant rats, rats given injections of 0.2 µg estradiol-17β/day, and rats given estradiol and 2 mg of progesterone/day. Rats were given i.p. injections from a Yoshida ascites sarcoma. No tumor growth was observed in intact rats with normal estrous cycles; dead sarcoma cells were found in the uterine lumen in 3 rats. Four of 8 ovariectomized rats showed tumor growth in the uterus. Three of 6 ovariectomized rats given estrogen showed tumor growth; 3 of 6 ovariectomized rats given estrogen and progesterone showed tumor growth. Five of 6

ovariectomized rats given progesterone without other treatment showed tumor growth, and all 7 ovariectomized rats given progesterone and a single dose of estrogen developed tumors. Twenty of 23 intact rats in the 4th day of pseudopregnancy developed tumors, and 7 of 8 rats in the 5th day of pseudopregnancy developed tumors. Scratching the endometrium, and inoculating sarcoma cells directly into the endometrial stroma, permitted tumor growth in the uterus of rats with normal estrous cycles, a finding which may suggest that the uterine epithelium is important for resistance of the uterus to tumor development.

1215 MAMMARY TUMOR DEVELOPMENT IN BR6 MICE: HORMONAL STIMULATION. (E.) Lee, A. E. (Imperial Cancer Res. Fund, London, England). *Brit J Cancer* 24(3):568-573, 1970.

The effect of hormone injections and pituitary implantation on the growth of mammary tumors was investigated in mice. Hormone injections consisted in 1.0 mg prolactin, 0.5 I.U. adrenocorticotrophic hormone, 50.0 µg growth hormone, 0.5 µg estrone and 0.5 mg progesterone; in some cases, hormone injections were accompanied by injections of 5-hydroxytryptamine (5-HT). When breeding females with regressed pregnancy-dependent mammary tumors were given hormone injections, 3 of the 6 treated mice showed recurrence of tumor growth after 1 course of treatment; 2 of these tumors regressed again after hormone injections were stopped. When virgin mice were given hormone injections with 5-HT, all 6 treated mice developed tumors at an earlier age (75 and 60 wk for hormone and hormone-and-5-HT-treated mice, resp.) than in untreated controls, where the average age at tumor development was 94 wk. Once they had appeared, all tumors grew independently of further hormone stimulation. When virgin mice were given hormone injections as above but without prolactin and with increased progesterone, tumors again appeared at a lower age than in controls. When 11 virgin mice were given pituitary implants under the kidney capsule at 10 wk of age, all 11 developed mammary tumors at a mean age of 58 wk, while only 4 of 10 untreated mice developed tumors, at a mean age of 83 wk. When the pituitary implant was removed from 6 mice (bearing 7 tumors), 3 tumors continued to grow, 1 remained the same, and 3 regressed. When hormone injections were combined with pituitary implants, the average age at tumor development was not lowered significantly from that at which tumors began to appear in mice given pituitary grafts without hormone treatment. The development and early age of tumor appearance in mice given pituitary implants was not reduced in ovariectomized mice given pituitary grafts.

1216 EPIDERMAL CHALONE AND CELL PROLIFERATION IN A TRANSPLANTABLE SQUAMOUS CELL CARCINOMA IN HAMSTERS: I. *IN VIVO* RESULTS. (E.) Elgjo, K. (Rikshosp., Oslo, Norway) and H. Hennings. *Virchow Arch Zellpath* 7(1):1-7, 1971.

The effects of a partially purified pig skin extract containing the growth regulating factor, epidermal

chalone, on the growth parameters of a transplantable keratinizing hamster epithelioma were studied. Five tumor-bearing hamsters were injected i.p. with 50 mg chalone and vinblastine (VB, 1.5 mg/kg) or 50 mg liver powder and VB, or VB only; the animals were sacrificed 4 hr later and mitoses in the tumor was inhibited 34% in the chalone-treated animals compared to the controls. DNA synthesis was depressed 84% at 8 hr after chalone injection compared to liver extract injection. Mitotic duration in livers treated with liver powder, chalone or VB was 0.6 hr, 0.9 hr and 0.8 hr, resp. Three daily i.p. injections of 50 mg of chalone into tumor-bearing animals resulted in small ulcerations at the site of injection, but no regression of tumors was observed.

- 1217 HISTOCHEMICAL STUDIES ON MUCOSUBSTANCE IN HUMAN GASTRIC CARCINOMA. (E.) Sugimoto, A. (Hiroshima U. Sch. Dent., Japan) and K. Kirimoto. *Acta Histochem Cytochem* 3(3):81-104, 1970.

The histochemical properties of the gastric mucosa of human gastric carcinomas were investigated; case material included 65 specimens of early gastric carcinoma, 135 cases of advanced carcinoma, 50 non-cancerous lesions, and 20 specimens of normal mucosa from duodenal and rectal tissue. Tissue sections were prepared and stained with any of 10 different stains, including mucicarmine, alcian blue-periodic acid-Schiff reaction (AB-PAS), alcian blue, azure eosin, and hematoxylin eosin. Two different types of mucosubstances with different staining properties occurred in normal and non-cancerous gastric mucosa: mucosubstances which stained pink in the periodic acid-Schiff reaction alone when the AB-PAS reaction was applied and which did not stain with alcian blue, mucicarmine, or metachromasia; and mucosubstances which stained with alcian blue alone or with both alcian blue and periodic acid-Schiff in the AB-PAS reaction and which stained intensely with mucicarmine and toluidine blue. These 2 mucosubstances were characteristic of the gastric mucosa proper (e.g., the cardiac, corporal and pyloric regions) and of the region of intestinal metaplasia (e.g., the area characterized by goblet cells), resp. Histochemically, most gastric carcinomas were of the latter type; 78% of tissue preparations from cancer patients were stained with the AB-PAS reaction and were positive for both alcian blue and periodic acid-Schiff. Early and advanced gastric carcinomas had similar staining properties, with 78.5% of cases in each stage belonging to the goblet-type mucosubstance category. Of 114 tubular adenomas, 57 showed "marked" goblet-cell type mucosubstance staining, and 24 showed gastric mucosa proper type mucosubstance staining. Of mucocellular carcinomas, 14 were of the goblet-cell type and none were gastric mucosa proper staining type. Of 14 papillary adenocarcinomas, 7 were of the goblet cell type and 7 were of the gastric mucosa proper type. Apparently, intestinal metaplasia may be a background change of gastric carcinoma.

- 1218 HODGKIN'S DISEASE: ONE ENTITY OR TWO? (E.) Smithers, D. W. (Roy. Marsden Hosp., London, England). *Lancet* 2(7686):1285-1288, 1970.

The age-distribution of 475 patients with Hodgkin's disease was investigated in order to test the hypothesis that this condition represents 2 disease entities, including an inflammatory condition and neoplastic condition. That hypothesis is based on the bimodality of the age-incidence curve for Hodgkin's disease, in which peaks occur for males at age 35-50 yr and 55-60 yr. In the present survey, age-incidence peaks occurred at age 25-26 yr and 51-55 yr for all patients; the peaks for males were more pronounced than for females, who were seen to have a less prominent late age peak than males. When 414 cases were classified into a less malignant lymphocytic group and a more malignant mixed-cellularity, intermediate, and lymphocytic depletion group, it was found that the bimodality of the age-incidence curve was preserved for men. Age peaks for the less malignant form of Hodgkin's disease occurred at age 26-30 yr and 51-55 yr. Age peaks in the more malignant groups occurred at age 30-31 yr and 56-60 yr. The age-incidence curve for the nodular-sclerosis type of Hodgkin's disease showed only the early peak, and these curves were similar for both men and women. The findings appear to suggest that Hodgkin's disease is a single progressive neoplastic condition, unified from lymphocytic predominance through mixed cellularity to lymphocytic depletion. The bimodality of the age-incidence curve might be explained by the development of host immunity which leads to the nodular-sclerosis pattern and, in some cases, by regression of the disease in its second stage.

- 1219 CYTOGENETIC ANALYSIS OF MULTINUCLEATE ASCITIC TUMOR IN GOLDEN HAMSTERS. (E.) Shidoy, T. (Framingham Union Hosp., Mass.), T. H. Ingalls and A. Herranen. *Arch Environ Hlth* 22(1):141-150, 1970.

Chromosome patterns of an ascitic fluid sarcoma that had been induced by 3-methylcholanthrene in the hamster in 1951 were analyzed. Metaphase plates recovered from the serous fluid of 11 animals revealed a modal number of 96 compared to the expected 44 in normal animals, and the DNA content of the tumor cells was higher than that of normal thymus tissue (22.4 vs 6.8 $\mu\text{g}/10^6$ cells). Karyotype analysis (standard grouping of the 2 sex chromosomes and 6 morphologically distinct autosomal groups) of 38 metaphase plates from the ascitic tumor revealed hyperploidy (to various degrees) in all except the D group which was hypoploid (5 or 6 chromosomes instead of the expected 8). Members of the F group demonstrated a definite trend toward trisomy.

- 1220 CHROMOSOME ABERRATIONS IN FANCONI ANEMIA. (E.) Visfeldt, J. (Commun. Hosp., Copenhagen, Denmark) and E. Mortensen. *Acta Path Microbiol Scand* 78(5):545-550, 1970.

The diagnosis of Fanconi's aplastic anemia in a 7-yr-old girl was confirmed by chromosome analysis: the girl died of her condition within a year after initial admission to the hospital. X-ray examination of her ossification centers showed development

corresponding to that of a 2-yr-old. Chromosome analysis revealed aberrations of the chromatid type; no dicentrics, tracentrics or rings were found. There were no mitoses in endoreduplication, and only a few tetraploid cells were seen. The patient showed 34% of cells with structural abnormalities, as compared to 2% of abnormal cells in the blood of 1 of her parents. She had 22% chromatid gaps and isochromatid gaps (compared to 1% for a normal parent); chromatid exchanges were observed in 9% of cells (compared to 0% in a normal parent.) Fanconi's anemia has been correlated with an increased tendency to develop leukemia and other neoplastic diseases; it is suggested that the chromosome aberrations noted in Fanconi's anemia may predispose patients to changes induced by carcinogenic agents.

1221 THE RISK OF LUNG CANCER IN MALES WITH BULLOUS DISEASE OF THE LUNG. (E.)

Stoloff, I. L. (Philadelphia Dept. Publ. Hlth., Pa.), P. Kanpfsky and L. Magilner. *Arch Environ Hlth* 22(1):163-167, 1970.

The association between bullous disease and lung cancer was investigated in 49,902 persons appearing at the Central Philadelphia Mass Radiography Unit in a 7 month period. Of 17,708 males without lung bullae, there were 34 with proved primary lung cancer; of 49 men with lung bullae, there were 3 with cancer. The prevalence rate of cancer among men without bullae was 1.9/1000, compared to a prevalence rate of 61/1000 for men with bullae. The relative risk of contracting cancer in white men was calculated as 40, while the relative risk of cancer for nonwhite men was calculated as 27. No women appeared in the survey having both bullous disease and lung cancer. A retrospective survey of all men with lung cancer presenting at the Unit since 1947 showed that prevalence rates of bullous disease in 890 men with cancer were 12.1/1000 (white) and 54.2/1000 (nonwhite).

1222 TYROSINE HYDROXYLASE ACTIVITY IN A TRANS-PLANTABLE ISLET CELL TUMOR OF GOLDEN HAMSTER. (E.)

Axelsson, S. (Inst. Anat. Histol., U. Lund, Sweden), L. Cegrell and A. M. Rosengren. *Experientia* 26(9):998-999, 1970.

Islet cell tumors in hamsters were examined for the presence of an enzyme system catalyzing the conversion of tyrosine to dopa. Islet cell tumors were transplanted to adult hamsters of both sexes and allowed to grow for 4-12 wk; 22 tumors were analyzed for tyrosine hydroxylase activity. Three tumors contained 3,4-dihydroxyphenylacetic acid, and 9 contained 3-methoxy-4-hydroxyphenylacetic acid, both endogenous dopamine metabolites. Tyrosine hydroxylase enzyme which converts tyrosine to catechol derivatives in the islet cell tumors was present in amounts of 20 nmole/g/hr. Tetrahydrofolic acid increased the enzyme activity by 340% compared to controls, while 2,2'-bipyridyl decreased enzyme activity to 18% of control values. The rapid turnover of dopamine could explain the occurrence of 3-methoxy-4-hydroxyphenylacetic acid in the tumor; the latter compound is usually present in tumors

derived from the neural crest, including neuroblastoma, ganglioneuroma, and pheochromocytoma.

1223 THE POTENTIALITY OF OUT-OF-CYCLE ACUTE LEUKEMIA CELLS TO SYNTHESIZE DNA. (E.)

Stryckmans, P. (Jules Bordet Inst. Ctr. Tumor, Free U. Brussels, Belgium), G. Delalieux, J. Manaster and M. Socquet. *Blood* 30(6):697-703, 1970.

The fraction of nonproliferating acute leukemic cells which retain the ability to synthesize DNA was determined. Venous blood from 18 patients with acute leukemia was exposed to UV light for 30 sec, and DNA synthesis as measured by uptake of ^3H -thymidine was observed. Incorporation of ^3H -thymidine revealed the fraction of leukemic cells in normal DNA synthesis (S-cells). The percentage of ^3H -thymidine labeled non-S (out of cycle, in G_1 or G_2) circulating leukemic blasts in the UV-exposed samples ranged from 94-100%, with the exception of 1 case with 70%, a patient who had undergone chemotherapy with daunomycin and vincristine until 3 days before the experiment. In cells not exposed to UV, the amount of non-S cells incorporating ^3H -thymidine was zero. The DNA synthesizing activity of the UV exposed cells probably represented DNA repair replication. Apparently, the nonproliferating acute leukemia blasts were not cells which have stopped dividing at maturation ("end cells"), but resting cells.

1224 CYTOLOGIC STUDIES OF TUMORS: L. CLONAL PROLIFERATION OF FOUR STEMLINES IN THREE HEMATOPOIETIC TISSUES OF A PATIENT WITH RETICULOSARCOMA. (E.)

Obara, Y. (Hokkaido U., Sapporo, Japan), M. Sasaki, S. Makino and C. Mikuni. *Blood* 37(1):87-95, 1970.

Peripheral blood, lymph node tissue, and bone marrow from a 47-yr-old female with reticulosarcoma were examined cytologically to detect chromosome irregularities associated with this condition. Four chromosomally different cell lines were found in the 3 tissues examined. Each line had a similar karyotype marked by trisomy for E_{16} , E_{17} and E_{18} , and the loss of A_1 , two F and two 4 C elements; M and R markers were also found. Lymph node cells showed an abnormal chromosome picture in 4 of 70 cells examined; abnormal cells were characterized by M_1 , R_1 and R_2 markers and trisomy for E_{16} - E_{18} , and the loss of A, F and C elements, as above. In peripheral blood not stimulated with phytohemagglutinin, 60% of cells had M_1 , M_2 , M_3 , and R_1 markers, trisomy for E_{17} and E_{16} , and the characteristic loss of A, F and C elements. These cells may have been derived from the lymph node cell line. Bone marrow cells had M_1 and M_4 markers, trisomy for E_{16} - E_{18} , and loss of A, F, and C elements. Peripheral blood had the highest variability in malignant cells. On the basis of the similarity in the marker chromosomes in the cell lines, the original stem line of the 4 may have been the line from the lymph node, perhaps the primary site of the malignancy.

- 1225 HYPOESTROGENISM AND ENDOMETRIAL CARCINOMA. (E.) Liu, W. (Youngstown Hosp. Ass., Ohio). *Acta Cytol* 14(9):583-585, 1970.

The cytohormonal status of patients with endometrial carcinoma and the possible relationship between cytohormonal effect and the exfoliation of endometrial carcinoma cells was investigated. Subjects were 200 patients with primary endometrial cancer diagnosed as having adenocarcinoma or adenoacanthoma of the endometrium and ranged in age from 38-77 yr. Vaginal aspiration smears were taken, and the cytohormonal effect was assessed and expressed as percentages of superficial, intermediate and parabasal squamous cells in the smears. Sixty-two percent of the patients had a minimum of superficial cells, 28% had a moderate number, and 10% had a large number. Fifty-two percent of patients had minimal cytologic hypoestrogenism, 10% had moderate hypoestrogenism and 38% had severe hypoestrogenism. Among patients with 20% or more exfoliated superficial squamous cells, 92% had definite or suspected tumor cells; and among patients with 80% or more intermediate cells, only 60% had tumor cells. Since endometrial carcinoma cells were not as often found in parabasal or intermediate cell smears as in smears with many superficial cells, it was concluded that the association between cytologic hypoestrogenism and endometrial carcinoma is not as clear as has been believed.

- 1226 MAMMARY TUMOR DEVELOPMENT IN BR6 MICE: OVARIAN INFLUENCES AND 5-HYDROXYTRYPTAMINE. (E.) Lee, A. E. (Imperial Cancer Res. Fund, London, England). *Brit J Cancer* 24(3):561-567, 1970.

The importance of ovarian influences during early pregnancy on tumor development was studied by observations in pregnant and pseudopregnant mice and in mice injected with 5-hydroxytryptamine (5-HT). Ninety-three percent of new tumors appeared after the 12th day of pregnancy, the mean time of tumor appearance being 17 days. New tumors which subsequently regressed after parturition appeared later than those which showed incomplete regression, the first group appearing after a mean of 18 days of pregnancy, and the second group of tumors appearing after a mean of 16 days. Tumors which regressed completely after parturition recurred by the 12th day after the next pregnancy in 64% of cases, while tumors which showed only partial regression after parturition resumed growth earlier, 66% recurring before day 12. Female mice made pseudopregnant by pairing with vasectomized males showed 12 instances of recurring tumor during 4 cycles of pseudopregnancy; 9 tumors did not recur, and 3 new tumors appeared. Apparently, pseudopregnancy may stimulate the growth of an established regressed tumor, but does not produce new tumors. Alkaline phosphatase activity in normal mouse mammary glands showed a uniform increase in growth during pregnancy without a marked increase at any particular time. Newly pregnant mice were given injections of 3.0 mg of 5-HT to terminate pregnancy, with the result that treated mice seemed to develop tumors earlier than usual, often during the second preg-

nancy. However, no difference in tumor development was observed between control and 5-HT-treated virgin females, treated mice developing tumors in 13/22 cases, and untreated controls developing tumors in 8/16 cases. Apparently, while 5-HT may have influenced tumor development in breeding mice, it had no effect on virgins.

- 1227 ULTRASTRUCTURE OF GLOMUS TUMORS AND ARTERIOVENOUS GLOMERULA. (Ger.) Lüders, G. (U. Clin. Tubingen, Germany), W. Schlote and M. Reinhard. *Arch Klin Exp Derm* 238(4):398-416, 1970.

Ultrastructural findings on surgical specimens from a glomus tumor of a 34-yr-old patient from a family with dominant autosomal hereditary multiple glomus tumors are presented. A variety of epithelioid cells seem to be histogenetically derived from smooth muscle cells. These epithelioid cells must have lost their characteristic myofilaments centrifugally during transformation; they present now a light perinuclear halo populated with organelles. These cells are never found at the direct border of the vascular lumen where a thin layer of active endothelial cells is usually present. Large amounts of histiocytes and mast cells are usually found along with the endothelial cells. The existence of a functional relationship between the endothelial, mast cells and histiocytes is assumed and the term of "myoepithelioid" cells is suggested for the light cells to indicate their histogenetic origin.

- 1228 CARCINOMA OF THE OESOPHAGUS AND GASTRIC SURGERY. (E.) MacDonald, J. B. (Gen. Hosp. Nottingham, England), J. G. Waissbluth and M. J. S. Langman. *Lancet* 1(7688):19-20, 1970.

The hypothesis that gastric surgery, especially surgery for peptic ulcer, predisposes to cancer of the esophagus was tested in 203 patients with esophageal cancer and in 208 patients with rectal cancer. Of the patients with esophageal cancer, 73% had squamous cell tumors, 4% were anaplastic, and 2.5% had adenocarcinomas. Two percent of esophageal cancer patients had undergone previous gastric surgery, and 4 patients had achalasia of the cardia. One percent of rectal cancer patients had histories of gastric surgery. The operations performed were gastrectomy using the Billroth procedure. The finding failed to confirm a clear association between gastric surgery and esophageal cancer.

- 1229 THE DEVELOPMENT OF "SPONTANEOUS" NEOPLASTIC TRANSFORMATION *IN VITRO* OF CELLS FROM YOUNG AND OLD MICE. (E.) Franks, L. M. (Imperial Cancer Res Fund, London, England) and S. Henzell. *Europ J Cancer* 6(5):357-364, 1970.

The capacity of cell lines established in culture from various mouse tissues to produce tumors when injected in syngeneic mice was investigated. Cell lines were initiated from tissues of embryo mice, young mice, and aged mice; explants were taken from kidney, bladder, brain, lung and heart. Cells were inoculated into mice (3×10^6 cells) after periods

in culture varying from 90 days to more than 2 yr. The length of the slow growth phase in culture before the onset of rapid *in vitro* cell growth was recorded. Six of 14 cell lines from young mice and 10 of 21 lines from old mice produced tumors on s.c. inoculation into mice after periods in culture ranging from 190-638 days. Latent periods for tumor development ranged from 15-316 days. The tumor developing capacity of cell lines was apparently not related to the length of the slow growth rate of the cells. No relationship was found between tumorigenicity and strain or age of the donor tissue, method of initiation or transfer of cultures. Ten of the tumor-producing cell lines had already undergone malignant change before 200-250 days in culture.

- 1230 CHROMOSOMAL DNA REPLICATION PATTERN IN HUMAN TUMOR CELLS *IN VITRO*. (E.) Kucheria, K. (All-India Inst. Med. Sci., New Delhi, India). *Brit J Cancer* 24(3):484-488, 1970.

In vitro tritiated thymidine labeled human solid tumor cells were examined for chromosome DNA replication patterns at the terminal stages of the S-period in cell lines of male and female origin. Cell lines used from rhabdomyosarcoma revealed karyotypic diversity with the appearance of marker chromosomes. In cell lines of female origin heavily labeled median size chromosomes of the group XX6-12 appeared while in those of male origin one of the chromosomes of group 21-22Y appeared more heavily labeled. In all cell lines (rhabdomyosarcoma, astrocytoma, neuroblastoma) one of the chromosome pair of group 13-15, pair no. 17 and chromosomes of the groups 19-20 and 21-22 showed early termination of their DNA synthesis. DNA replication of chromosomes in neoplastic cells is basically unchanged despite changes in chromosome number and morphology with no significant relationship of age of patient or origin of neoplastic cells to this pattern.

- 1231 CYTOPLASMIC DESMOSOMES IN NEOPLASTIC KERATINOCYTES OF SQUAMOUS CELL CARCINOMA. (Ger.) Klingmuller, G. (U. Clin. Bonn, Germany), H. U. Klehr and Y. Ishibashi. *Arch Klin Exp Derm* 238(4):356-365, 1970.

The presence of intracytoplasmic desmosomes in de-differentiated keratinocytes from specimens of 6 surgically removed squamous cell epithelial carcinomas was ascertained by electron microscopy. These desmosomes appeared to be highly differentiated and identical to normal desmosomes; they were referred to as "desmosome equivalents" and their length was 0.35-1.2 μ . The desmosomes appeared either singly or in filamentous structures suggesting that their formation may occur independently of the cell membrane. The presence of rough endoplasmic reticulum close to the nucleus of the neoplastic keratinocyte indicated an intensification of metabolic processes. The cell surface of the transformed keratinocytes exhibited very few desmosomes but presented an increased amount of microvilli hindering the occurrence of normal inter-cellular contacts within the tissue.

- 1232 INHIBITION OF WALKER 256 CARCINOSARCOMA GROWTH BY DIETARY ZINC DEFICIENCY. (E.) DeWys, W. (U. Rochester Sch. Med. Dent., N.Y.), W. J. Pories, M. C. Richter and W. H. Strain. *Proc Soc Exp Biol Med* 135(1):17-22, 1970.

The effect of a zinc-deficient diet on the development, growth, and survival from Walker 256 carcinoma was investigated. Rats fed on normal diet, zinc-supplemented diet, and zinc-deficient diet were given i.m. injections of 2×10^6 Walker carcinoma cells. The median survival time for rats fed with the normal diet was 18.5 days after injection of the tumor cells, while the mean survival time for rats on a zinc-deficient diet was 46 days. In rats fed normal or zinc-supplemented diets, 23-25/25 of the rats had died before day 60, while only 12/25 of the rats on the zinc-deficient diet were dead at this time. Five rats in the zinc-deficient group remained tumor-free at day 60; while all living rats in the other experimental groups had tumors by this day. The growth of tumors in zinc-deficient rats was markedly decreased compared to tumor growth in rats on the normal diet or rats on the zinc-supplemented diet; by day 15 average diameters of tumors in normal-fed, supplemented zinc-fed, and deficient zinc-fed rats were 3.1, 2.8 and 1.1 cm, resp.

- 1233 PROTEIN-BOUND CALCIUM IN TUMORS. (E.) Anghileri, L. J. (Essen Tumor Res. Clin., U. Essen, Germany). *Naturwissenschaften* 57(11):547-548, 1970.

Levels of protein-bound calcium in lymphosarcoma- and Ehrlich carcinoma-bearing animals were determined. Animals bearing s.c. transplants of lymphosarcoma or Ehrlich carcinoma were given i.p. injections of 10 μ C of $^{45}\text{CaCl}_2$, killed 24 hr later, and assayed for calcium in blood, liver and kidney. More labeled calcium was found in supernatants from normal animals than in supernatants from tumor-bearing animals. Values for ^{45}Ca in blood of lymphosarcoma-bearing animals were 2.3%, and for controls, 5.5%. Values for the blood of Ehrlich carcinoma-bearing animals were 2.7% and, for random-bred albino controls, 4.6%. However, liver and kidneys of Ehrlich carcinoma-bearing animals contained more ^{45}Ca than did liver and kidneys of controls, probably because this tumor is high in soluble proteins.

- 1234 EXPERIMENTAL RETINOBLASTOMA: I. MORPHOLOGY AND BEHAVIOR OF CELLS CULTIVATED *IN VITRO*. (E.) Huang, L. H. (Wills Eye Hosp. Res. Inst., Philadelphia, Pa.), T. W. Sery, M. M.-S. Chen, A. S. M. Cheung and A. H. Keeney. *Amer J Ophthalmol* 70(5):771-777, 1970.

The growth in culture of cells from 9 cases of human retinoblastoma was investigated. While all 9 cultures remained viable for more than 2 yr, 4 showed proliferation after transfer, and 5 simply maintained viability. Cultures were apparently comprised of cell types divisible into 4 categories: microglial and glial cells, ganglion cells, large polygonal cells with no dendritic processes and pleomorphism

of nucleoli, and large elongated cells resembling fibrocytes. All of these cell types may have been derived as aberrant variations of the malignant cells of retinoblastoma. One culture was transferred in 60 serial passages and may be a malignant strain containing the original retinoblastoma cell type. When cultured retinoblastoma cells were injected in neonatal rabbits and mice, no lesions were observed either at the inoculation site or at microscopy.

- 1235 CHROMOSOMES AND CAUSATION OF HUMAN CANCER AND LEUKEMIA: VI. BLASTIC PHASE, CELLULAR ORIGIN, AND THE Ph¹ IN CML. (E.) Sandberg, A. A. (Roswell Park Mem. Inst., Buffalo, N. H.), D. K. Hossfeld, E. Z. Ezdinli and L. H. Crosswhite. *Cancer* 27(1):176-185, 1971.

The incidence of Ph¹ chromosome-negative cells in patients with chronic myelocytic leukemia was investigated in a survey of 107 cases. Of these patients with chronic myelocytic leukemia, 79 were Ph¹-positive; most Ph¹-negative patients were elderly (60-yr-old or more) while most Ph¹-positive patients were younger (50-yr-old or less). In 6 patients with Ph¹-positive chronic myelocytic leukemia, marrow cells were Ph¹-negative prior to any therapy in some and after treatment of various types in others. In these patients, the M:E ratio was high, ranging from 2-240:1. The observation of Ph¹-negative cells in some patients with chronic myelocytic leukemia would seem to cast doubt on the hypothesis of a unicellular stem cell origin for Ph¹-positive cells in chronic myelocytic leukemia.

- 1236 THE PATTERN OF CELL GROWTH IN RETICULUM CELL SARCOMA AND LYMPHOSARCOMA. (E.) Peckham, M. J. (Roy. Marsden Hosp., Sutton, Surrey, England) and E. H. Cooper. *Europ J Cancer* 6(5):453-463, 1970.

The pattern of cell proliferation in human reticulum cell sarcoma and lymphosarcoma are reported based on labeling studies and DNA measurement in fresh lymph-node biopsy tissue. Tumor cell labeling indices were between 20 and 40% in all but one biopsy in reticulum cell sarcomas and showed considerable variation in lymphosarcomas with an accumulation of cells in the G₂ phase or a hold-up in the S phase. No correlation could be established between labeling index and patient response to treatment. Hypotetraploid reticulum cell sarcomas tended to localize to one or two lymph-node areas whereas tumors showing modal DNA contents in the diploid range tended to diffuse and result in generalized disease.

- 1237 CONCURRENT INFECTIOUS MONONUCLEOSIS AND ACUTE LEUKEMIA. (E.) Freedman, M. H. (Child. Hosp. Los Angeles, Calif), G. H. Gilchrist and G. D. Hammond. *JAMA* 214(9):1677-1680, 1970.

Nine patients with concurrent infectious mononucleosis (IM) and acute leukemia were observed, and 4 cases were described. The age of the patients at diagnosis of leukemia ranged from 3.75-35 yr; 7 of the cases were males. Eight of the cases were

diagnosed as acute lymphatic leukemia; the 35 yr-old patient had acute monocytic leukemia. IM was diagnosed from 3 months to 3.75 yr after the diagnosis of leukemia in 7 cases, and 3 and 3½ months before the diagnosis of leukemia in 2 cases. Heterophil antibody titers ranged from 1:112-1:896 before and after guinea pig kidney absorption. The etiological relationship of IM and acute lymphatic leukemia remains unclear.

- 1238 VAGINAL TRICHOMONIASIS AND PRECANCEROUS STATES OF THE CERVIX: A PRELIMINARY REPORT. (E.) de Carneri, I. (U. Padua, Italy) and Di Re, F. *J Obstet Gynec Brit Comm* 77(11):1016-1018, 1970.

The incidence of vaginal trichomoniasis infection among women with normal and precancerous vaginal smears was investigated. The case material was comprised of 1732 vaginal smears from adult women in a town in Northern Italy. Scrapings from the ectocervix and an endocervical swab were grown in cysteine-peptone:liver-maltose medium; smears were divided into 5 classes ranging from normal cytology to neoplastic cytology (Papanicolaou). *Trichomoniasis vaginalis* was found in 315 subjects or 18.2% of those examined. Seventy-four percent of the smears were classified as Class I (normal cytology). Less than 34% of the expected incidence of trichomoniasis infection was seen in Class I smears while 94% of the expected incidence in Class II smears was observed. More than 234% of the expected incidence of infection was found in Class III vaginal smears, which were characterized by dyskaryosis and basal cell hyperactivity. More than 119% of the expected number of infections occurred in smears from Classes IV and V; smears in these classes have the morphological properties of neoplastic cells. On the basis of these findings, it appears plausible to suggest that there is a relationship between cervical neoplasia and *Trichomoniasis vaginalis* infection.

- 1239 BLUE NEVUS OF THE PROSTATE GLAND. (E.) Jao, W. (Michael Reese Hosp. Med. Ctr., Chicago, Ill.), D. F. Fretzin, M. L. Christ and L. M. Prinz. *Arch Path* 91(2):187-191, 1971.

Ultrastructural studies in a case of blue nevus of the prostate gland are described. A multinodular prostate weighing 35 g was removed from a 76-yr old white man; the gland was diffusely gray in color with dark brown streaks and showed characteristic features of benign hyperplasia under light microscopy. The fibromuscular stroma was extensively infiltrated with stellate and spindle-shaped cells with finely granular brown cytoplasmic pigment which stained positively with the Masson-Fontana stain, but negatively with Prussian blue. Electron microscopic examination showed numerous electron-dense coarse granules diffusely distributed in the cytoplasm of spindle-shaped cells; the morphology of these granules was typical of mature melanosomes. Several granules resembling premelanosomes were also observed. The prostatic lesion in this case appears to be histologically analogous to the common blue nevus as opposed to the cellular blue nevus of the skin.

- 1240 THE CYTOLOGY, DISTRIBUTION AND FUNCTION OF THE NEOPLASTIC CELLS IN LEUKEMIA RETICULO-ENDOTHELIOSIS. (E.) Berg, B. (U. Hosp. Lund, Sweden) and L. Brandt. *Scand J Haemat* 7(6):428-434, 1970.

The characteristics of neoplastic cells found in aspiration biopsy from peripheral blood, bone marrow, spleen, liver, and lymph nodes of patients with leukemic reticuloendotheliosis were investigated. Biopsy material was obtained from 4 male patients aged 35-55 yr. Neoplastic cells found in material from the various sites were similar morphologically. In all cases, cells were round and about twice the size of normal lymphocytes; nucleoli were uncommon, as were mitoses, and the cytoplasmic margin had many villous particles. In all cases, spleen and liver material contained a higher proportion of neoplastic cells than blood and bone marrow. The amount of neoplastic cells in liver and spleen samples reached maximum values of 80% and 88%, resp., while maximums for blood and bone marrow did not exceed 55% and 60%, resp. There was no convincing evidence of phagocytosis of neoplastic cells in the peripheral blood of any patient. Incorporation of ^3H -thymidine by neoplastic cells was also low, possibly indicating that the neoplastic tissue had low proliferative capacity.

an evaluation of 22,000 neuroblastoma cells, 126 tumor cells were found in mitosis; the overall mitotic index was 0.572%. The change in the labeling index and in labeling intensity of neuroblastoma cells was a function of time after ^3H -thymidine injection. Percentage of labeled mitoses rose from 10-90 between 1-7 hr after label injection, subsequently decreasing to a low of 15% at 35 hr post-injection. Data from labeled mitoses indicated a minimum G_2 phase time of 1-2 hr and a mean DNA synthesis time of about 27-28 hr. At 1½ hr after ^3H -thymidine injection, 11% of all neuroblastomas were labeled and 53, 18, and 1.3%, resp., of cells with large, intermediate, and small nuclei were labeled. The neuroblastoma cells seem to comprise 2 populations (one, which was initially labeled, of proliferating cells with large nuclei and one, which was initially unlabeled, of non-proliferating cells with small nuclei); the non-proliferating state appears to be temporary, and the majority of tumor cells seem to be able to undergo cell division.

- 1243 FACILITATION OF RAT MAMMARY TUMOR GROWTH BY BCG. (E.) Piessens, W. F. (Massachusetts Gen. Hosp., Boston), F. L. Lachapelle, N. Legros and J. C. Heuson. *Nature* 228(5277):1210-1211, 1970.

The effect of administration of bacillus Calmette-Guerin (BCG) to rats bearing mammary tumors induced by 7,12-dimethylbenz(a)anthracene (DMBA) was investigated. Rats were given a single s.c. dose of 1 mg BCG when 1 mammary tumor had developed following treatment with the carcinogen. BCG did not affect the primary tumors; but the total tumor surface/rat, the number of tumors/rat, and the number of rats developing new tumors were significantly higher in the BCG-treated group. At 4 wk after 7,12-dimethylbenz(a)anthracene injection, 6 new tumors had developed in controls and 17 in BCG-treated animals. At 5 wk after carcinogen-treatment, 3 controls and 13 BCG-treated rats had developed new tumors. At 6 wk after carcinogen treatment, total new tumor area/rat was 85 cm² for controls and 325 cm² for BCG-treated rats. Facilitation of tumor growth by BCG may be accounted for by immunological tumor enhancement.

- 1244 DIABETES MELLITUS AND CANCER. (E.) Anonymous. *Brit Med J* 4(5729):191, 1970.

A survey of the data on the association of diabetes mellitus and cancer of various sites indicates that 13% of cancer patients with diabetes have cancer of the pancreas in 1 study. Recent studies, however, have shown that among men with diabetes, death from cancer of all types other than pancreatic cancer is less frequent than expected; deaths from rectal and respiratory tract cancer were especially rare in diabetics. Among women with diabetes, death from cancer was slightly more frequent than expected and probably hid an increased risk of cancer of the pancreas and cancer of the uterus. The observation of pancreatic duct hyperplasia in diabetes may point to a common etiology for diabetes and pancreatic cancer.

- 1241 CHANGES IN CELLULAR PROPERTIES DURING THE LONG-TERM SERIAL CULTURE OF LUNG CELLS OF NEWBORN HAMSTER AND THE TRANSFORMATION INTO A CELLS. (E.) Matsuya, Y. (Res. Inst. Tuberc. Leprosy Cancer, Tohoku U., Sendai, Japan) and I. Yamane. *Tohoku J Exp Med* 102(1):37-49, 1970.

Cellular properties, morphology, and karyotypic changes were followed during the course of cell establishment of neonatal hamster lung cells. After 23 transfers, cells that had been grown in a serum albumin fortified (BSA) medium became capable of sustaining a constant stable growth in the presence or absence of albumin (until after 90 transfers the growth promotion of albumin was negligible), and after 27 transfers the cells exhibited an ability to grow at low inoculation densities (300 cells/plate). Chromosomal studies of the cells revealed that the typical diploid karyotype persisted after the cells demonstrated the capacity to grow at low inoculum density until the 37-44th transfers when the karyotype shifted at the tetraploid range with a modal number of 45, and the cells acquired a neoplastic morphology at the 70th transfer.

- 1242 CELL PROLIFERATION IN NEUROBLASTOMA. (E.) Wagner, H. P. (U. Hosp., Berne, Switzerland) and H. Käser. *Europ J Cancer* 6(5):69-372, 1970.

The proliferation of neoplastic cells was investigated in cells from a female patient with generalized neuroblastoma. Tumor cell samples were taken from different parts of a superficially growing metastasis. Labeling index, median grain-count and mitotic index were estimated by autoradiography after pulse-labeling with tritiated thymidine. In

- 1245 HEREDITARY POLYPOSIS OF THE COLON. (E.) Wyndham, N. (Newtown, New South Wales, Australia). *Med J Aust* 57(19):866-869, 1970.

Hereditary polyposis of the colon expressed in 4 generations of an Australian family was examined. The polyposis gene has been described as a dominant gene transmitted to about half the children of a parent possessing it. In the 34 members of the family examined, 2 had polyposis and 8 had polyposis with carcinoma. All 3 of the first generation father's children had polyposis and carcinoma, and 4 of the 12 members of the third generation had polyposis with carcinoma. Symptoms of polyposis had their onset in the fourth and sixth decades of life for the members of the family for whom data are available. Carcinomas arising in connection with polyposis in this family were located in the colon, rectum, or anus.

- 1246 ANNULATE LAMELLAE IN HUMAN PARATHYROID ADENOMA. (E.) Boquist, L. (Inst. Path., U. Umea, Sweden). *Virchow Arch Zellpath* 6(3):234-246, 1970.

Ultrastructural examination of 2 human parathyroid adenomas revealed annulate lamellae in the tumor cells. The patients, a middle-aged man and woman, had tumors in 1 of the lower parathyroid glands, and both had symptoms of hyperparathyroidism. Tumors were composed mainly of chief cells and a few oxyphil cells; these cells showed an abundance of mitochondria. Nuclei of chief cells were of varying sizes and occasional giant nuclei were observed; in some cases prominent Golgi bodies and endoplasmic reticulum were seen. Annulate lamellae were often seen in the chief cells, but seldom in oxyphil cells; they occurred both in the perinuclear region of cells, and in other regions of the cytoplasm. No intranuclear lamellae were observed. Annulate lamellae were composed of parallel arrangements of double membranes in straight, curved, semi-circular or circular configurations; membranes were smooth-surfaced and merged at times to form pores. In transverse section, lamellae were cylindrical with electron-dense peripheral areas and less dense interiors. Individual lamellae were often separated by electron lucent spaces with cisterns of granular endoplasmic reticulum situated at the ends of, or around, the lamellae. Circular or semi-circular lamellae sometimes encompassed cytoplasmic ground substance or amorphous material of varying electron opacity. Mitochondria were often completely or partially confined within lamellae.

- 1247 CHROMOSOMAL EVIDENCE FOR THE SECONDARY ROLE OF FIBROBLASTIC PROLIFERATION IN ACUTE MYELOFIBROSIS. (E.) Van Slyck, E. J. (Henry Ford Hosp., Detroit, Mich.), L. Weiss and M. Dully. *Blood* 36(6):729-735, 1970.

Cytogenetic studies were performed on myeloblasts derived from the peripheral blood of a 22-yr-old white female with acute myelofibrosis and agnogenic myeloid metaplasia in order to determine whether

fibroblastic proliferation associated with acute myelofibrosis is a primary or a secondary feature of the disease. Chromosome analyses were carried out on 24 cells, showing a consistent abnormality. In the A group, the number 2 chromosomes were normal, but only 1 normal number 1 chromosome was seen, and there was a marker chromosome larger than the normal number 1 but with a submetacentric centromere. Only 1 number 3 chromosome was seen, and there was an extra submetacentric chromosome the size of a C group chromosome. These abnormalities were interpreted as a 1-3 translocation. The patient's bone marrow fibroblasts were normal karyotypically, as were her lymphocytes. Apparently, the basic abnormality in acute myelofibrosis is not fibroblastic proliferation; rather, the chromosome abnormality in the myeloid cells appears to mark these elements as the primary aberrations associated with acute myelofibrosis.

- 1248 MELANOSOME AND LYSOSOME: I. LYSOSOMAL ACTIVITY IN RELATION TO GROWTH OF MELANOMA. (E.) Ohtaki, N. (Tokyo Med. Dent. U., Japan). *Bull Tokyo Med Dent Univ* 17(2):89-102, 1970.

An electron microscopic examination was conducted on a Harding-Passey mouse melanoma; lysosomal activity in the tumor, the latency of lysosomal enzymes, and the relationship between lysosomal enzymes and tumor growth were also investigated. Melanoma melanocytes and melanophage cells were observed in the melanomas. Melanoma melanocytes contained mitochondria in abundance, a well-developed endoplasmic reticulum, numerous free ribosomes, and melanosomes. Melanophage cells were similar in appearance to melanoma melanocytes, but they possessed compound melanosomes. Lysosomal enzymes in the melanoma were found in the supernatant, microsomal, and mitochondrial fractions of the tumor homogenate. The heaviest fraction, which sedimented at 700 x g x 10 min, possessed relatively low tyrosinase activity and contained 50% of the succinic dehydrogenase activity. Acid phosphatase activity showed no latency, but cathepsin activity increased with deoxycholate treatment under hypotonic conditions. All enzyme activities increased with increases in tumor wt. However, enzyme activity usually reached peak values at 5-9 days after the commencement of tumor growth, and then declined thereafter. Succinic dehydrogenase activity increased with increases in tumor wt for 21 days before falling off. Tumor wt increased for 29 days, after which necrosis set in.

- 1249 ULCERATIVE COLITIS AND CARCINOMA OF THE BILE DUCTS. (E.) Converse, C. F. (U. Hosp. Cleveland, Ohio), J. W. Reagan and J. J. DeCosse. *Amer J Surg* 121(1):39-45, 1971.

The association of ulcerative colitis and cancer of the bile ducts was investigated in 29 cases and in a survey of cases recorded in the literature. The literature yielded 3,009 cases of chronic ulcerative colitis; in 12 of these patients carcinoma of the bile ducts was also present (0.4%). In the series of 29 cases, 3 of which are described for

the first time, both chronic ulcerative colitis and bile duct cancer occurred in all cases. Most of these patients, were male; average age at onset of symptoms was 25.1 yr (range, 7-59 yr). The severity of ulcerative colitis in bile duct cancer patients was greater than in the usual patient with ulcerative colitis. A nonrandom association appears to exist between ulcerative colitis and bile duct carcinoma; cholangitis often seemed to precede the onset of bile duct carcinoma.

- 1250 B.C.G. AND LEUKAEMIA. (E.) Hems, G. (U. Dept. Soc. Med., Aberdeen, Scotland) and A. Stuart. *Lancet* 1(7691):183, 1971.

The protection from leukemia afforded by childhood vaccination with bacillus Calmette-Guerin (BCG) was investigated in the British population. Vaccination records have been kept since 1954, indicating that BCG vaccination of 13-yr-old children in England and Wales was performed on 7% of these children in 1954, and on 65% by 1967. The incidence of leukemia in these periods was determined, and it was found that leukemia mortality rates have declined in the latter half of the century. By 1970, when 30-60% of the 15 to 19-yr-old population had been vaccinated, the mortality from leukemia had declined from 35×10^{-6} (recorded in 1954 for unvaccinated children) to 24×10^{-6} . While the observed decline in the leukemia mortality rate concurrent with the increasing efficiency of BCG vaccination programs may represent effect and cause, it is also possible that the decline in leukemia mortality was due to other factors.

- 1251 B.C.G. VACCINATION AND LEUKEMIA MORTALITY. (E.) Berkeley, J. S. (Edinburgh). *Lancet* 1(7692):241, 1970.

The effect on leukemia mortality of vaccination with bacillus Calmette-Guerin (BCG) was investigated in 4 Scottish towns. BCG vaccination programs have been in effect in Glasgow since 1954, in Edinburgh and Aberdeen since 1953, and in Dundee since 1955. Leukemia mortality data show that death from leukemia in the 3 age groups 0-4 yr, 5-9 yr, and 10-14 yr increased in Edinburgh, Aberdeen and Dundee, while in Glasgow, the leukemia mortality rate for the 0-4 yr age group more than doubled. Increases in mortality rates were recorded in comparison to mortality data compiled from 1939-1948.

- 1252 CHROMOSOMES AND CAUSATION OF HUMAN CANCER AND LEUKEMIA: VII. THE SIGNIFICANCE OF THE Ph^1 IN CONDITIONS OTHER THAN CML. (E.) Rosselfeld, D. K. (Roswell Park Mem. Inst., Buffalo, N. Y.), T. Han, R. N. Holdsworth and A. A. Sandberg. *Cancer* 27(1):186-192, 1971.

Evidence was found that the Ph^1 chromosome condition is not entirely specific for chronic myelocytic leukemia; 3 cases were examined, 2 of acute myeloblastic leukemia and 1 of chronic erythroleukemia (Di Guglielmo's syndrome) in which the Ph^1 chromo-

some was present. The patients were male of 42-43 yr; in each case the disease was fatal. Chromosome analyses showed Ph^1 -positive cells in bone marrow in 40-100% of the cells examined. The process leading to the development of a Ph^1 chromosome apparently affected the bone marrow cells at or beyond the level of the stem cells. Cases in the literature in which Ph^1 chromosomes were associated with conditions other than chronic myelocytic leukemia were also reviewed.

- 1253 THE ULTRASTRUCTURE OF CARDIAC MYXOMA. (E.) Williams, W. J. (Welsh Natl. Sch. Med., Cardiff), D. Jenkins and D. Erasmus. *Thorax* 25(6):756-761, 1970.

A cardiac myxoma which was excised from the left atrium of a 41-yr-old man was examined by electron microscopy. It appeared as a soft, friable mucoid mass attached by a pedicle to the posterior aspect of the anterior commissure of the mitral valve. Histologically, the myxoma consisted of abundant, amorphous mucoid tissue with scattered single and grouped rounded or stellate cells. The predominant cell type in the myxoma was about 10μ in diameter, of uniform structure, and occurred singly or in tight clusters of 2-4 cells; no giant cells were seen. Nuclei were often irregular in outline; nucleoli and mitotic figures were absent. Numerous Golgi complexes were seen in the cytoplasm; there was a moderate amount of lamellar rough endoplasmic reticulum, and free ribosomes, mitochondria, and glycogen granules. No formed collagen was found, and there was little evidence of pinocytosis. Fine intracytoplasmic fibrils were frequent. Apparently, the myxoma cells were biosynthetically active and were responsible for the production of the stroma cells. The myxoma was thought to be a neoplasm rather than a thrombus.

- 1254 CROWN GALL: AN EXPERIMENTAL MODEL FOR USE IN THE QUANTITATIVE REGULATION OF GENETIC INFORMATION IN THE PRODUCTION OF TUMORS. (Fr.) Guille, E. (Fac. Sci. Orsay, France) and F. Quetier. *Bull Cancer* 57(2):217-238, 1970.

Hybridization of DNA-DNA and RNA-DNA from tumor tissue was studied and compared with those of healthy tissue. The nuclear DNA of crown gall could not be shown to be of bacterial origin; the sedimentation density of DNA of the tumoral tissue was the same as that of healthy tissue. However, it is possible that the bacterial DNA present in the tumor cell was too small a fraction to be detected by the gradient ultracentrifugation method. From experiments of molecular hybridization of DNA and RNA of tumor tissue with nucleic acids of bacterial origin, it appeared that there were sequences common to DNA of tumor tissue and bacterial DNA, and that part of the new sequences had been transcribed into the established tumor tissue. Three types of new sequences existed in the tumor tissue: the sequences common to hybrid DNA and bacterial DNA; the sequences specific to bacterial DNA; and the sequences of hybrid DNA integrated into different loci of the matrix.

The sequences present in tumor tissue were essentially constituted of repetitions of guanylic acid and cytidylic acid. The model for quantitative regulation of genetic information is based on the principal properties of the hybrid DNA which are: hybridization with cytoplasmic ribosomal RNA; its high degree of redundancy; and its desynchronized labeling with respect to the classical nuclear DNA. This model is applicable to the chromomere of higher organisms conceived as a unit of structure and function and to the genetic information of the neoplastic event.

- 1255 ALDOLASE ISOZYME PATTERNS OF REPRESENTATIVE TUMOURS IN THE HUMAN NERVOUS SYSTEM. (E.) Kumanishi, T. (Brain Res. Inst., Niigata U., Japan) and F. Ikuta. *Acta Neuropath* 16(3):220-225, 1970.

The aldolase isozyme activities of human nervous system neoplasms were investigated. Mixed astrocytomas with oligodendroglioma, plump cell type and anaplastic cell type, were shown by thin layer polyacrylamide gel electrophoresis to have high levels of activity of aldolase C in the 5-membered hybrid set of A-C. Malignant gliomas, neuroblastomas, meningiomas, pinealomas, cranio-pharyngioma and pituitary adenomas, on the other hand, showed relatively low levels of aldolase activity, and, in some cases, no appreciable aldolase activity.

- 1256 SPECIFIC CHROMOSOME ANOMALY ASSOCIATED WITH AUTONOMOUS AND CANCEROUS DEVELOPMENT IN MAN. (E.) Muldal, S. (Christie Hosp., Manchester, England), R. Elejalde and P. W. Harvey. *Nature* 229(5279):48-49, 1970.

The over- and under-representation of chromosome types in neoplastic tissues was examined by a computer method which sorted chromosomes according to their centromere indices and their lengths. A total of 60,000 chromosome measurements were made. A significant gain was found in all samples of neoplastic tissue in the chromosomes of centromere index 0.50-0.45 and length 5.97-2.44 μ ; chromosomes in this range averaged 11.73% in neoplastic tissue and 5.54% in normal tissue. Neoplastic tissues showed depressed numbers of chromosomes with centromere indices of 0.16-0.05 and with lengths of 5.97-2.44 μ ; neoplastic tissues showed 3.07% of these chromosomes, and normal tissue, 10.11%. The excess in "chromosome 16" chromosomes in malignant cells apparently was due to iso-chromosomes and translocations, especially the acrocentrics. Such translocations may lead to the loss of normal nucleolar organizers, and it is possible that malignant cells contain D and G translocations which are not known constitutionally, having lost the nucleolar organizer present in normal cells.

- 1257 FUNCTIONAL SEQUENCES MODULATED BY MORPHOLOGICAL TRANSITIONS IN HUMAN LYMPHOID CELLS GROWN *IN VITRO*. (E.) Drewinko, B. (M. D.

Anderson Hosp. Tumor Inst., Houston, Tex.), J. M. Trujillo and C. F. Tessmer. *Science* 171(3967):185-186, 1971.

The morphological changes exhibited by human lymphocytes derived from a patient with lymphoma and cultured for 5 yr were observed. Reticuloid fusiform cells and lymphocytoid and plasmacytoid round cells predominated; binucleate cells and transitional cells were also abundant. Indirect immunofluorescence tests indicated that the cells synthesized gamma globulin. Round cells comprised 80% of fluorescent cells, with fusiform cells making up 10% of fluorescent cells. The median generation time from 1 cell division to the next daughter cell was 36 hr. Most cells underwent changes in shape from round to fusiform and back to a round form. Dividing fusiform cells occasionally gave rise to an elongated and a round daughter cell, more often to 2 fusiform cells. Daughter cells were sometimes seen to fuse and produced a single binucleate cell; the fusion cell then dissociated into a mobile round cell, or it divided to give 4 round daughter cells. Round cells demonstrated marked pyroninophilia and showed intense fluorescence when exposed to fluorescein-labeled antiserum to human gamma globulin, while fusiform cells showed little or no fluorescence. This finding apparently indicates that these cells can only synthesize immunoglobulins when they assume a round shape. It also appeared that human immunoglobulin-producing cells undergo cyclic morphological changes which are expressions of functional differentiation.

- 1258 CAROTID BODY TUMORS: FAMILIAL AND BILATERAL. (E.) Wilson, H. (Dept. Surg. U. Tennessee, Memphis). *Trans South Surg Ass* 81:241-246, 1970.

The diagnosis and treatment of tumors of the carotid body were reviewed with special attention to the familial occurrence of these lesions. Although most carotid body tumors are benign, a few are malignant and spread to contiguous structures and to regional lymph nodes. Carotid tumors occurring in a familial distribution are more likely to be bilateral than isolated carotid tumors. In a newly reported case, a bilateral carotid body tumor was discovered in a 65-yr-old man; 5 of 6 siblings and 3 of their children also have carotid body tumors, 2 of which are bilateral. One brother had no tumor, but his son did.

- 1259 A GANGLIONEUROMA IN THE ADRENAL MEDULLA OF A RAT BEARING A PREOPTIC-ANTERIOR HYPOTHALMIC LESION. (E.) Barofsky, I. (Mass. Coll. Pharm. Boston), E. Matalka and A. B. Russfield. *Cancer Res* 30(12):2913-2916, 1970.

The discovery of a ganglioneuroma in the adrenal medulla of a male rat which had received a unilateral preoptic-anterior hypothalamic lesion at 3 months is reported. The tumor was discovered on autopsy when the rat was 1 yr old. Two well-differentiated components were found: mature ganglion cells and neural

tissue; no normal medullary cells were seen in the tumor. Neural tissue was found in 21 of the 27 other rats with lesions, and in 28 of the 40 intact controls. Ganglion cell differentiation was found in 12 of 27 other rats with lesions, and in 13 of 40 controls. However, none of the other rats developed ganglioneuromas. The stimulus which might lead to ganglion cell differentiation may be a sustained neural stimulation of the adrenal medulla resulting from a pre-optic lesion.

1260 THE CHROMOSOMAL ABERRATION OF DOUBLE-MINUTES IN THREE GLIOMAS. (E.) Mark, J. (Inst. Path. U. Lund, Sweden) and I. Granberg. *Acta Neuropath* 16(3):194-204, 1970.

The chromosomes of about 70 human malignant gliomas were studied, and the clinical and pathological features of 3 tumors with a regular occurrence of double-minutes (small paired chromatid bodies in addition to the ordinary chromosomes) were determined. The double-minutes were extremely small and ranged in number between 1 and 100 per cell. Their occurrence was not related to any specific deviations in the ordinary chromosomes, although the double minutes might be derived from one or more pulverized chromosomes.

1261 MALIGNANT DEGENERATION OF GONADAL DYS-GENESIS. (Ger.) Schaller, A. (2nd U. Women's Clin., Vienna, Austria), P. Fischer and E. Golob. *Geburtsh Frauenheilk* 30(11):980-985, 1970.

A case of gonadal dysgenesis which developed into malignancy is described in an 18-yr-old girl with uterine hypoplasia and amenorrhea. In the course of laboratory tests, no estrogen effect was seen in the vaginal smear, the urine contained no pregnandiol and the histological diagnosis was "undifferentiated" gonadal dysgenesis. The oral mucosal smear showed no sex chromatin, and the chromosomal determination of lymphocyte cultures showed a 46 XY karyotype. The association of the XY constellation with malignancy was confirmed in this case by the development of a tumor within 2 yr of the diagnosis of gonadal dysgenesis, although no tumor growth was detected in the first gonadal streak. Metaphases with normal diploid male chromosomal configuration associated with malignant tumor-specific marker chromosomes were found within the tumor.

1262 FAMILIAL OCCURRENCE OF INTRACRANIAL MENINGIOMA. (Ger.) Grunert, V. (Neurosurg. U. Clin., Vienna, Austria), J. Horcajada and M. Sunder-Plassmann. *Wien Med Wschr* 120(46):807-808, 1970.

A study of 2 male siblings (53 and 49 yr-old) with intracranial meningioma is reported. Both cases were operated on within 11 months of each other, after histological confirmation of the intracranial meningioma. The older brother had a suprasellar meningioma removed completely, and in the other brother a large meningioma was located at the third ventricle and in both lateral ventricles, which could not be completely extirpated. Another member of this family, a sister, also died of a brain tumor, but the type of tumor was not specified. The possibility of a genetic susceptibility to intracranial meningioma is discussed.

1263 THE EARLY RADIOLOGICAL CHANGES IN PULMONARY AND PLEURAL ASBESTOSIS. (E.) Fletcher, D. E. (North Lonsdale Hosp., Barrow-in-Furness, England) and J. R. Edge. *Clin Radiol* 21(4):355-365, 1970.

1264 A BREAST SARCOMA CONTAINING RHABDOMYOSARCOMATOUS AND OTHER METAPLASTIC ELEMENTS. (E.) Bird, C. C. (Dept. Path., U. Aberdeen, Scotland). *J Path* 101(3):286-289, 1970.

1265 TRICHOMONIASIS AND CANCER OF THE UTERINE CERVIX. (Rus.) Barats, A. M. (21st Hosp. Sverdlovsk, USSR). *Sovet Med* 33(10):147, 1970.

1266 CANCER OF THE OTHER BREAST. (Fr.) Menye, P. A. (Dakar, Senegal), D. Simaga and S. Atangane. *Bull Soc Med Afr Noire Lang Franc* 15(1):15-24, 1970.

SUBJECT INDEX

- 2-ACETAMIDOFLUORENE
 - BILE DUCT LIGATION, N-HYDROXY-2-ACETAMIDOFLUORENE, ADRENALECTOMY (0908)
- N-ACETOXYACETAMIDOFLUORENE
 - 2-(N-HYDROXY)ACETAMIDOFLUORENE, PHOSPHATE ESTER, ULTIMATE CARCINOGEN (0909)
- 2-ACETYLAMINOFLUORENE
 - DIETARY INDOLE, URINARY BLADDER TUMORS (0907)
- ACTINOMYCIN D
 - MAMMARY TUMOR SUPPRESSION, 7,12-DIMETHYLBENZ(A)ANTHRACENE (0932)
- ADRENAL GLAND
 - ADRENALECTOMY, BILE DUCT LIGATION, N-HYDROXY-2-ACETAMIDOFLUORENE (0908)
 - CORTEX, LIPID HYPERPLASIA, ANILINE, RAT (0925)
 - CORTICAL CARCINOMA, ESTRADIOL, RAT (0890)
 - MEDULLA, PREOPTIC-ANTERIOR HYPOTHALAMIC LESION, GANGLIONEUROMA, RAT (1259)
 - POSTCASTRATIONAL ADRENAL TUMORS, STRAIN VARIABILITY, MICE (1199)
- AFLATOXIN
 - ACID PHOSPHATASE, LYSOSOMAL ENZYME ACTIVITY, CHICKEN (0916)
 - ANALYTICAL METHODS, REVIEW (0881)*
 - B1, B2, G1, G2, ANIMAL FEEDS (0991)*
 - B1, LABELED ACETATE INCORPORATION, HUMAN SKIN LIPIDS (0918)
 - B1, LIVER NUCLEIC ACID SYNTHESIS, PHENOBARBITAL (0919)
 - B1, RNA SYNTHESIS, LIVER CELLS (0914)
 - B1, TWO DIMENSIONAL THIN LAYER CHROMATOGRAPHY, FOOD PRODUCTS, PEANUTS (0990)*
 - LIPOTROPE-DEFICIENT DIET, LIVER TUMORS (0915)
 - LIVER, ENZYME ACTIVITY, CITRIC ACID CYCLE (0920)
 - METABOLISM IN LIVER, DEGRADATION PRODUCTS (0917)
- AGE
 - DISTRIBUTION, HODGKIN'S DISEASE (1218)
 - TUMORIGENICITY OF MOUSE CELL LINES, IN VITRO NEOPLASTIC TRANSFORMATION (1229)
- AIR POLLUTION
 - URBAN, CARCINOMA OF THE TONSIL, CANINE RESPIRATORY TRACT CARCINOMA (1183)
- ALKYLATING AGENT
 - CYCLOPHOSPHAMIDE, CARCINOGENICITY, RAT, MOUSE (0906)
 - 1,3-PROPANE SULFONE, 1,4-BUTANE SULFONE, RATS, NEUROGENIC TUMORS (0905)
 - TRENIMON, MUTAGENESIS, HAMSTERS, BONE MARROW (0903)
- AMINOACETONITRILE
 - METABOLISM, DIMETHYLNITROSAMINE (0961)
- AMINO ACID
 - ARGININE DEPRIVATION, POLYOMA VIRUS, INFECTION (1112)
 - LEUKOSIS, ANTIGEN, VIRUS (1027)
- AMP
 - CELL SURFACE ALTERATIONS, ROUS VIRUS, POLYOMA VIRUS (1079)
- ANILINE
 - LIPID HYPERPLASIA, RAT ADRENAL CORTEX (0925)
- ANTIBODY
 - GROSS LEUKEMIA VIRUS, GLOMERULONEPHRITIS, MOUSE (1034)
 - GROSS LEUKEMIA VIRUS, IMMUNO-FLUORESCENT FOCUS ASSAY (1036)
 - PRODUCTION, CANCER PATIENTS, 17D YELLOW FEVER VIRUS VACCINE (1140)
 - TITERS, SURVIVAL TIME, CANCER PATIENTS, FLAGELLIN (1119)
 - TITERS IN HODGKIN'S DISEASE, EPSTEIN-BARR VIRUS (1025)
 - VIRUS, HUMAN SERA, EPSTEIN-BARR, HERPES (1063)
- ANTIGEN
 - AMINO ACID, LEUKOSIS, VIRUS (1027)
 - CANCER TEST, BASIC PROTEIN, LYMPHOCYTE SENSITIZATION (1197)
 - DEN-86, HEPATOMA, DIETHYLNITROSAMINE, RAT (0956)
 - EPSTEIN-BARR, CLONED HUMAN LEUCOCYTES (1021)
 - LEUKEMIA, ISOLATION, MAN (1141)*
 - LEUKEMIA, LYMPHOMA, THYMUS-LYMPHOID TISSUE (1121)
 - MELANOMA, ACUTE LEUKEMIA, HUMAN (1129)
 - POLYPEPTIDE, AVIAN MYELOBLASTOSIS VIRUS (1065)
 - PROTEIN SYNTHESIS, MYELOMA CELL-LYMPHOMA CELL HYBRID (1124)
 - RESPONSE, DEFECTIVE VIRUS, SV40 (1100)
 - S BLOOD, SS PHENOTYPE, BREAST CANCER (1130)
 - SARCOMA, FERRIDEXTRAN SPOFA, RAT (0900)
 - SARCOMA, HUMAN ADENOVIRUS TYPE 12, GROWTH ENHANCEMENT, HAMSTER (1050)
 - SERUM, MYELOMA, PROTEINS (LAMBDA) (1127)
 - SPECIFICITY, 3-METHYLCHOLANTHRENE, DIFFERENTIAL ANTIGENICITY SARCOMAS (0942)
 - SURFACE, PROTEIN COMPONENTS, AVIAN TUMOR VIRUS (1085)
 - TUMOR-SPECIFIC, RAT MAMMARY CARCINOMA, ISOLATION (1132)
 - TUMOR-SPECIFIC NEOANTIGEN, VIRUS, HUMAN MAMMARY CARCINOMA (1131)
 - VARIATION, IMMUNOCHEMICAL ANALYSIS, POLYOMA VIRUS (1107)
 - VIRAL, HERPES, CELL MEMBRANES (1062)
 - VIRUS, EPSTEIN-BARR VIRUS, MAREK'S

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain two-hundred abstracts and twenty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume IX covers the scientific literature published from July 1970 through June 1971. A cumulative subject and author index for Volume IX will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows:

REVIEW

- 1267 ON THE PROBABLE ROLE OF ONCOGENIC VIRUSES IN HUMAN EPIDEMIOLOGY. (E.) Clemmesen, J. (Danish Cancer Registry, Copenhagen). *Rev Europ Etud Clin Biol* 15(9):934-937, 1970.

Evidence for a viral etiology in human malignant diseases was reviewed. Human epidemiology has historically given little support to the hypothesis of a viral factor for human cancer. Microepidemics, familial cancer cases, and cancer occurring in a single dwelling place were not convincing on statistical analysis. A stronger argument for a viral genesis for neoplasia is that viral oncogenesis is clear for animals, and that no relevant dissimilarities have been thought to exist which distinguish men from animals in point of susceptibility to infection. However, it seems that some significant differences do exist between human and animal populations which might explain the presence in the latter of viral oncogenesis and its absence in the former. Among these differences is the prevalence of inbreeding in animal populations, and its rarity in human populations; reduced immunocompetence in inbred populations might explain the occurrence of viral infections of epidemic proportions. The exposure to chemical carcinogens in urban air, tobacco smoke, and industrial processes represents another feature distinguishing human and animal populations. Hygiene, moreover, has developed only in human populations. Recent evidence has shown that epidemics of malignant neoplasia have occurred in Africa (Burkitt's lymphoma) and among Chinese in Southeast Asia (nasopharyngeal carcinoma); viruses have been implicated in both these conditions. Whether virus transference from person to person is decisive in the genesis of these diseases, or whether viral infection is only a contributing factor for oncogenesis is uncertain. (24 references)

- 1268 THE PROTOVIRUS HYPOTHESIS: SPECULATIONS ON THE SIGNIFICANCE OF RNA-DIRECTED DNA SYNTHESIS FOR NORMAL DEVELOPMENT AND FOR CARCINOGENESIS. (E.) Temin, H. M. (McArdle Lab., U. Wisconsin, Madison). *J Nat Cancer Inst* 46(2):III-VII, 1971.

The provirus hypothesis suggests that "instructions" for neoplastic transformation may be transmitted vertically from cell to cell despite the fact that the original germ cell does not have these instructions encoded on its DNA; the mechanism for this transmission according to the provirus hypothesis is RNA-directed DNA synthesis which allows for changes in the DNA of cells without a random mutation having occurred. In normal cell development, RNA dependent DNA polymerase might bring about alteration of cells by causing the production of new DNA in one cell by RNA transferred to that cell from another; the combination of new and preexisting DNA in the former cell would promote variability in progeny cells. The usual process leading to neoplastic growth could be a variation in the normal physiological evolution of new DNA as a result of RNA-dependent DNA synthesis. The initial change in cell DNA leading to the transmission of instructions for neoplastic transformation might come about as a result of a virus, a chemical, or a physical stimulus applied to the cell. Transmission of these instructions might then proceed by means of DNA produced in

cells by RNA transferred to them from the original cell containing the instructions for cancerous change. (18 references)

- 1269 UNIFIED THEORY ON THE BASIC MECHANISM OF NORMAL MITOTIC CONTROL AND ONCOGENESIS. (E.) Cone, C. D., Jr. (Langley Res. Ctr., Hampton, Va.). *J Theor Biol* 30(1):151-181, 1971.

Results of an investigation of a fundamental mechanism for natural mitotic control associated with intracellular ionic balance and its effect on membrane potential difference were formulated into a theory of cytogenetic etiology and maintenance of the malignant state. There appears to be a positive correlation between the degree of mitotic activity of somatic cells and transmembrane potential level; large potential gradients within the cell membrane may have indirect secondary effects on intracellular conditions by producing steric modifications of the cell surface structure, resulting in alteration of membrane permeabilities for various ionic and molecular species. Since DNA synthesis is an essential prerequisite for normal mitosis, intracellular ionic environments associated with a given membrane potential level could act to regulate various osmotically associated aspects of metabolism connected with DNA synthesis through regulation of mRNA transcription or by activation or repression of the activity of already-formed enzymes. A proposed system of feedback interactions is feasible in which intracellular ion concentrations associated with the membrane potential act to influence cellular metabolic activity governing DNA synthesis, surface polymer production and mitochondrial activity; the latter two activities in turn may feed back to determine membrane potential levels. Since a number of oncogenic viruses exist which produce surface antigenic changes in somatic cells which are transformed, it is possible that their oncogenic action is entirely due to alteration or redirection of surface-associated polymer metabolism affecting membrane potential levels and allowing for increased mitotic activity. The closeness to which cell surfaces can approach and the tenacity with which they bond depend almost entirely upon the nature and specificity of the surface polymers. The modified antigenicity of malignant cell surfaces may be due to a stable alteration of the surface polymer preventing bonding between cells with consequent invasiveness and metastasis. Experimental data suggest increased sodium concentrations in excess of those normally used in tissue culture media show pronounced stimulatory mitotic effect, and trypsin which acts upon cell surface has produced acceleration of mitotic activity. The primary theoretical concept of mitogenic control which is proposed is based on experimental observations that a correlation exists between the electrical transmembrane potential level and the degree of mitotic activity for a substantial range of somatic cell types. - 1270 MITOCHONDRIAL DNA OF MALIGNANT CELLS. (Fr.) Paoletti, C. (Inst. Gustave Roussy, Villejuif, France) and G. Riou. *Bull Cancer* 57(3):301-334, 1970.

A characteristic structure in the mitochondrial DNA oligomer molecules has been described for malignant tumors which are invariably found in the white cells of chronic and acute myeloid and lymphoid leukemias; such structures were absent in normal white cells or in the benign hyperplasias. The modifications in the structure appear particularly in the length of the monocircular molecules, which suggests that this phenomenon may be due to an impairment of molecular mechanisms governing the synthesis of circular forms. The sequence of the base pairs in these abnormal oligomers, however, are similar to those in normal monomers, although one cannot exclude the existence of modifications, such as mutations, small zones of deletion or insertion, and methylation of the bases, etc. These data should be examined in the light of recent developments concerning the flotation density of mitochondrial DNA, which has been shown to differ in different species. The mechanism which may precipitate neoplastic tissue due to mitochondrial changes in DNA is discussed. (78 references)

- 1271 MORPHOLOGICAL ALTERATIONS OF THE THYMUS IN CANCER. (Rus.) Ageyev, A. K. (S. M. Kirov Acad. Med. Sci. Leningrad, U.S.S.R.). *Vop Onkol* 16(11):3-7, 1970.

A review of experimental data on the effect of thymectomy in very young animals on the enhanced development of tumors induced by viral or chemical agents is presented along with morphological data on thymic alterations detected in a series of patients who died of cancer. Of 28 patients 36-70 yr of age who died of lung, stomach, colon, pancreas, liver, uterine or mammary gland cancer, 21 had a decreased content of thymic parenchyma ranging from 0.5 to 6 g. The most distinct atrophic changes were noticed in patients who died between 36 and 55 yr-of-age; these alterations consisted in a considerable decrease in lymphocytes and a total lack of Hassall's bodies. The rate of decreased thymic function in tumor development is discussed. (31 references)

- 1272 THE ROLE OF THE THYMUS IN CARCINOGENESIS. (Rus.) Andrianova, M. M. (Inst. Nutr. Acad. Med. Sci., Moscow, U.S.S.R.). *Vop Onkol* 16(12):94-103, 1970.

The immunological implication of the thymus in the development of neoplasia is reviewed. The function of the thymus may be defined by 3 hypothetical mechanisms: 1) as a primary source of lymphocytes; 2) as an immune response generator by which the lymphocytes passing through the thymus become immune competent; 3) as a producer of a humoral factor effective in the development of the lymphatic system of the growing organism. Reference is made to the disruption of immune response by thymectomy of newborn animals which affects the synthesis of globulins and the capabilities of antibody formation. Thus viral carcinogenesis induced by polyoma virus, SV40 or some of the adenoviruses is enhanced in newborn thymectomized mice, rats, rabbits or hamsters. The enhancement by thymectomy of chemical carcinogenesis by 3,4-benzpyrene, 3-methylcholanthrene or

7,12-dimethylbenz(a)anthracene seems to be less evident. Thymectomy of the adult animal which has an established lymphatic system affects its immune defense mechanisms to a lesser extent. Lymphoid leukosis (Gross virus) constitutes a special case in terms of thymus involvement, in that the thymus seems to be necessary for its development. The mechanisms involved in the thymus-controlled immunological functions are still not well defined. (148 references)

- 1273 COMPARATIVE ONCOLOGY AND ENVIRONMENTAL CARCINOGENS. (E.) Dawe, C. J. (Bethesda Md.). *UICC Bull Cancer* 8(4):2-3, 1970.

Studies presently underway to investigate the development of neoplasms by aquatic animals and to elucidate possible etiological factors are reviewed. Bottom-feeding fish and filter-feeding mollusks provide test systems for investigating tumorigenesis by chemical water contaminants. Filter-feeders which accumulate many chemical contaminants in high concentrations in the course of ingesting food and the bottom-feeders which subsist on these mollusks demonstrate the carcinogenic properties of water contaminants. Epitheliomas developing in the mantles of the Sydney rock oyster are under study as are carcinomas and papillomas developed by California coastal croakers. Eel papillomas and papillomas of fish such as the founder and the sole are thought to be of viral origin. Neuroepitheliomas developed by Lake Michigan whitefish are also of interest in view of the extreme pollution of the Great Lakes. Lymphosarcomas developed by the northern pike, which is neither a bottom-feeder nor a scavenger, are also being studied. (no references)

- 1274 COMPARATIVE METABOLISM OF RADIONUCLIDES IN MAMMALS: A REVIEW. (E.) Stara, J. F. (Natl. Ctr. Radiol. Hlth., Cincinnati, O.), Nelson, R. J. Della Rosa and L. K. Bustad. *Health Phys* 20(2):113-137, 1971.

Animal and human metabolism studies for selected hazardous radionuclides are reviewed. Iodine-131 and the strontium isotopes have been shown to produce particularly deleterious effects when ingested. Iodine-131 produces most of its effects in the thyroid region due to localized deposition, with changes occurring more rapidly in rodents than in dog or man as well as the fetus in both animal and man. Alkaline earths and plutonium are deposited primarily in skeletal tissue and show their effects in osseous tissue and the blood-forming tissues; single dose effects include osteosarcomas and chronic exposure results in myelogenous leukemia, lymphosarcoma and reticulum cell sarcoma in animals and man. Beagles which are fed high levels of radioactive strontium develop myeloproliferative disorders resembling granulocytic leukemia in the acute form and myelofibrosis with myeloid metaplasia in the chronic form with the earliest onset occurring at 14 months-of-age with cumulative radiation doses of at least 100 rads and with an age-dose relationship in incidence. Similarities in the metabolism of radioisotopes in

many mammalian species permits a cautious extrapolation to man only when utilizing several species from different sub-families with life spans of different duration. (201 references)

- 1275 DRUGS, FOOD ADDITIVES, AND PESTICIDES IN RELATION TO ENVIRONMENTAL CANCER IN MAN: HISTORICAL PERSPECTIVES. (E.) Friedman, L. (Food Drug Admin., Washington, D. C.). *FDA By-Lines* 1(4): 179-184, 1971.

Accepted testing procedures for assessing the carcinogenicity of food additives, pesticides and other drugs in the human population were briefly reviewed. Demonstration of carcinogenicity for a given chemical is complicated by the fact that not all members of a population exposed to that drug will develop cancer; in addition, long periods of exposure are required for even potent carcinogens to produce cancer in humans. Moreover, laboratory findings do not necessarily predict the reaction of humans to the test agent (however, known human carcinogens generally elicit cancer in laboratory animals). A major task for research is to identify not the potent carcinogens whose effects are conspicuous but the weak carcinogens which are more likely to be overlooked. Chronic toxicity tests prolonged for the lifetime of the test animals are valuable for identifying agents potentially dangerous for man. Increasing concern that food additives and pesticides may have carcinogenic efficacy for men has created a need to know the carcinogenic potential of every food component. Test systems used to fill this need must employ several animal species, positive controls using chemicals similar to the test compound, and a variety of dosages. Drugs should be administered by routes analogous to the routes by which humans ingest them. A toxic response in the laboratory will show only that the agent is putatively carcinogenic for humans; a negative result, however, cannot exclude the possibility that the test substance is carcinogenic for man. Rapid test models for carcinogenicity should be developed in order to shorten the protracted lengths of time involved in lifetime evaluations of chemical carcinogens. (10 references).

- 1276 MYCOTOXINS AND THEIR ROLE IN ONCOGENESIS, WITH SPECIAL REFERENCE TO BLOOD DISEASES. (E.) Aleksandrowicz, J. (no affil), M. Czachor, A. Schiffer and B. Smyk. *Haemat Latina* 8(2):115-124, 1970.

The role of fungal metabolites (specifically mycotoxins) in carcinogenesis was investigated in a review of the literature. Two groups of diseases caused by mycotoxins were discussed: syndromes characterized by aplasia of the bone marrow such as erythro-, thrombo- and granulocytopenia; and syndromes resembling parenchymatous hepatitis or neoplastic proliferation of liver cells. Syndromes in the first group resemble acute leukemia in its early stages; fungi producing myelotropic mycotoxins include fungi of the *Fusarium* group. These mycotoxins which are steroids are often ingested via poorly stored grains on which the fungi grow.

The best known hepatotropic mycotoxin is aflatoxin, a metabolite of the fungus *Aspergillus flavus*. The cultivation of groundnuts in some parts of Africa and the consumption of moldy food products in other parts of the world have been implicated in carcinogenesis by means of aflatoxins. (24 references)

- 1277 A REVIEW OF OCCUPATIONAL CANCER. (E.) Emara, A. M. (Fac. Med. Cairo U., Egypt). *J Egypt Med Ass* 53(6):496-510, 1970.

The literature documenting the development of cancer in various sites resulting from occupational exposure to various carcinogenic agents is reviewed. The site of malignant development most heavily implicated in occupational carcinogenesis is the skin. Among carcinogenic agents thought to be responsible for the production of skin cancer are chimney soot (scrotal carcinoma), paraffin, oils and petroleum products, arsenic, and charcoal smoke. Lung cancer ranks second to skin cancer among the occupational cancers and has been reported in connection with nickel refining, chromate manufacture, asbestos exposure, coal tar exposure, arsenic exposure incurred in the course of sheep-dipping operations, iron mining, isopropyl oil manufacture, beryllium working, and wood working. Bladder cancer has been observed to have high incidences in workers with aniline dyes; xenylamine exposure has also been implicated. Ionizing radiation has been connected with leukemia, as has chronic benzol poisoning. Oil-soluble azo-dyes have been linked to liver tumors, and workers with arsenical sprays frequently develop liver tumors. Painting of luminous dials on watches has been connected with the development of osteogenic sarcomas. (142 references)

- 1278 CANCER GENETICS. (E.) Lynch, H. T. (Creighton U. Sch. Med., Omaha, Nebraska) and A. J. Krush. *South Med J* 64(suppl. 1):26-40, 1971.

The clinical properties and pathology of congenital malignant diseases were reviewed. Familial polyposis coli, inherited as a simple dominant, progresses to adenocarcinoma in about 40% of cases and can be expected to affect about 50% of the relatives of any patient. Gardner's syndrome (soft tissue and bony tumors and adenomatous polyps of the colon) has been observed in a series of 4 families of which 315 members were examined; of these 315, 73 exhibited symptoms of Gardner's syndrome, and 26 developed adenocarcinomas. Von Recklinghausen's disease (neurofibromatosis), is inherited as an autosomal dominant; patients develop sarcomas in 8-20% of cases, as well as cutaneous lesions, acoustic neuromas, and pheochromocytomas. Xeroderma pigmentosum, inherited as an autosomal recessive, may involve a variety of neurologic, endocrinologic and skeletal manifestations as well as skin lesions. Affected patients have a heightened sensitivity to solar radiation. The frequency of melanoma, inherited as an autosomal dominant is unknown, but has been estimated at about 3%. In 1 family, 3 of 14 members in 4 generations were affected. Other inherited malignancies include endometrial carcinoma and multiple nevoid basal cell

carcinoma. In the former condition, 1 study has shown that endometrial carcinoma occurred in 16% of first degree relatives in 154 cases. Cancer of the colon, including Peutz-Jeghers syndrome, Turcot's syndrome, solitary colon polyps, ulcerative colitis, and juvenile polyposis coli, are other conditions having familial occurrence. Hereditary factors may operate in some cases of mammary carcinoma. Approximately 50% of the neoplasms present at birth were neuroblastomas and 50% were sarcomas in one study. Other childhood conditions thought to be congenital include Wilms' tumor. (73 references)

- 1279 FAMILIAL ENDOCRINE ADENOMATOSIS: REPORT OF ONE CASE AND REVIEW OF THE LITERATURE. (Fr.) Croisier, J. C. (Hosp. Pitie, Paris, France), E. Azerad and J. Lubetzki. *Sem Hop Paris* 47(8):494-525, 1971.

The details of the reported case of familial endocrine adenomatosis included evidence of primary hyperparathyroidism, pancreatic islet cell damage (beta, alpha₁ and alpha₂), a thyroid nodule, nodular bilateral adrenocortical hyperplasia, and an increase in blood histamine and serotonin. The 2 dominant complaints on admission were hypoglycemic accidents and epigastric pain. A surgical intervention was necessary when the epigastric pain became violent; a perforated duodenal ulcer and 2 pancreatic tumors were revealed, at which time a gastro-duodenectomy was performed. Post-operative treatment is described. In general, the disease is familial and hereditary; it is transmitted genetically as an autosomic dominant, and characterized by proliferation foci in at least 2 endocrine glands. The most frequently affected glands are the parathyroid (88%), pancreas (84%), pituitary (51%), the adrenal cortex (41%) and the thyroid (27%). (249 references)

- 1280 CHRONIC MYELOID LEUKEMIA AND CHROMOSOMES. (Fr.) Berger, R. (Hosp. Child. Dis., Paris, France). *Rev Europ Etud Clin Biol* 15(9):1000-1007, 1970.

Cytogenetic studies of chronic myeloid leukemia have shown that the Philadelphia (Ph) chromosome is not the only karyotype anomaly in this disease. The Ph chromosome may characterize the acute stage of the disease whereas various other anomalies appear additionally in the chronic stage. Cases taken from the literature, having the Ph chromosome in common, were categorized into 5 groups of anomalies: the first, a loss of the G or Y chromosome; the second, an excess of C chromosomes and a rapid duplication of Ph, or an excess of D chromosomes coincident with Ph duplication; the third, an acquisition of F and C chromosomes accompanying the Ph duplication; the fourth, a loss in the E chromosomes and an increase in C chromosomes; and the fifth, anomalies different from the other groups, such as an excess in chromosome 16 or abnormalities in the A and B groups. Attention is drawn to the rarity of some of the combinations of anomalies, as in the case of the A and B groups and in E and F. The coexistence in the same

cell of an excess of F and a loss of chromosome 17-18 is quite exceptional. The possible interpretatic of such patterns of chromosome anomalies are discussed. (55 references)

- 1281 THE PROLIFERATIVE KINETICS OF THE ACUTE LEUKAEMIAS IN RELATION TO THEIR TREATMENT. (E.) Gavosto, F. (Gen. Med. Clin., U. Turin, Italy). *Rev Eur Etud Clin Biol* 15(10):1042-1047, 1970.

The growth pattern of human leukemias indicates that a proportion of the leukemic cell population is non-dividing. The pool of proliferating cells in acute human leukemias appears not to be self-maintaining; since dividing cells often produce cells which do not themselves proliferate, the cell birth rate in the proliferating portions of tumor cells is not exponential. Recent findings of human leukemia cells in the Go phase where cells are outside the cell cycle but are able to reenter it (under normal conditions or after treatment with chemical agents) suggest that cells in the Go phase play an important role in determining the growth kinetics of human leukemias. Part of the stem cell population responsible for tumor growth may be in the Go phase; at any time, a fraction of these Go cells may become activated to feed the proliferation cell pool of the tumor, while other Go cells remain outside the cell cycle in the non-proliferating pool and still other cells have returned to the Go phase after a period in proliferation. The possible value of agents which affect the number and/or behavior of cells in the Go phase and therefore the growth pattern of leukemia are discussed in terms of chemotherapy. (20 references)

- 1282 HYPERPLASIA AND CARCINOMA OF THE ENDOMETRIUM. (E.) Bettinger, H. F. (Roy. Women's Hosp., Melbourne, Australia). *Amer J Obstet Gynec* 109(2):194-197, 1971.

Advances in the understanding of the development of endometrial carcinoma from hyperplasia of the corpus uteri were reviewed. Since 1900, the association of hyperplasia and carcinoma has been observed and it has been suspected that the former condition is an early stage in the development of uterine or endometrial cancer. Stages of hyperplasia have been described, including "ordinary" hyperplasia and "atypical" hyperplasia; however, the factors determining the transition from one stage to the other remain unclear. Stimulation of the mucosa by estrogens, and hormonal imbalance have both been implicated in the genesis of hyperplasia and with its transition to "carcinoma in situ." The evidence is that the development of endometrial carcinoma is often preceded by many years by atypical hyperplasia glandular hyperplasia may not become malignant, but atypical hyperplasia, if not checked, will usually develop into carcinoma. It has been shown that hyperplasia may react well to treatment with progesterone; such treatment blocked development of carcinoma in one study. Although the evidence indicates that carcinoma of the endometrium is preceded by hyperplasia, it has also been shown that carcino

a may develop from endometrial cells in intermediate stages of hyperplastic development; carcinoma *in situ* and atypical hyperplasia are stages which may be bypassed. Opportunities for investigating the relationship between hyperplasia and carcinoma are being reduced by the practice of performing hysterectomies on many patients with early hyperplasia. - 1287 THE ONCOGENICITY OF TWO 1,1-DIARYL-2-PROPYNYL N-CYCLOALKYL CARBAMATES. (E.) Harris, P. N. (Eli Lilly Co., Greenfield, Ind.), W. R. Gibson and R. D. Dillard. *Cancer Res* 30(12):2952-2954, 1970.

The carcinogenicity of 1,1-bis(4-fluorophenyl)-2-propynyl N-cyclooctylcarbamate and 1,1-bis(4-fluorophenyl)-2-propynyl N-cycloheptylcarbamate was investigated in rats. Rats were maintained on a 3 month dietary regimen of the compounds in concentrations of 0.05, 0.1, or 0.25% (the cyclooctyl compound) and 0.01, 0.025 or 0.05% (the cycloheptyl derivative). Eighteen of 25 rats given the cyclooctyl compound developed malignant lymphoma; 2 developed malignant lymphoma and colonic adenocarcinoma, and 2 developed ileal adenocarcinoma. In these rats, the latency period for tumor development was 55 days. Nineteen of 37 rats given the cycloheptyl derivative developed malignant lymphoma and mammary adenocarcinoma; 2 developed mammary adenocarcinoma alone. The latency for tumors in the cycloheptyl derivative was 54 days.

- 1288 ALTERATIONS IN CREATINE KINASE ACTIVITIES DURING HEPATOCARCINOGENESIS. (Rus.) Ostretsova, I. B. (N. N. Petrov Sci. Res. Inst. Oncol. Leningrad, U.S.S.R.). *Vop Onkol* 16(11):102-104, 1970.

Mouse liver creatine kinase activity following s.c. administration of 0.04 ml carbon tetrachloride (single dose) increased by 30-40% in 2 days and 300% by 4 days after the injection. A gradual decrease in creatine kinase which reached normal values on the 3rd wk after the administration of the hepatotropic carcinogen was followed by a slight increase towards the end of the experimental period of 41 days. Similar trends in creatine kinase activity were noticed in transplanted 22a hepatomas in C3HA mice. The variations in carbon tetrachloride-treated mouse liver creatine kinase activities appear to be related to a carcinogenic rather than to a toxic action of carbon tetrachloride. The increase in creatine kinase activity in both hepatoma and liver tissue exposed to carbon tetrachloride may be related to an epigenetic unblocking of the protein synthesis determining genes.

- 1289 INVESTIGATIONS ON POSSIBLE CARCINOGENIC EFFECTS OF β -SEVIN. (Rus.) Zabezhinskiy, M. A. (N. N. Petrov Sci. Res. Inst. Oncol. Leningrad, U.S.S.R.). *Vop Onkol* 16(11):106-107, 1970.

Carcinogenicity of β -sevin, (2-naphthyl N-methylcarbamate), was tested in randombred white rats and CC57W mice. β -Sevin was given to 100 rats (50 mg s.c. once a wk for 33 months) and to 50 mice (20 mg once a wk for 24 months); 50 rats and 50 mice were treated p.o. daily with 25 mg and 10 mg. resp., 5 times a wk for 33 and 24 months, resp. S.C. administration of β -sevin produced fibrosarcoma at the injection site in 2 rats and s.c. rhabdomyosarcoma in 5 of the 29 surviving rats 21-30 months after the beginning of the experiment. Oral treatment induced a liver sarcoma and a fibroadenoma of the mammary gland in 1 rat, adenocarcinoma of the mammary gland in 3 rats, malignant thymoma in 1 rat and an ovarian

tumor in 1 of the 16 surviving rats 23-35 months after the beginning of the experiment. S.C. treatment with β -sevin induced lung adenoma in 4 mice, liver adenoma in 1 mouse, mediastinal hemangioma in 1 mouse and leukosis in 2 of the 10 surviving mice 15-20 months after the treatment. Oral treatment produced leukosis in 2 mice in 13-15 months, lung cancer in 2 mice in 15-16 months and liver hemangioma in 4 of the 26 surviving mice 15-23 months after the beginning of the experiment. The incidence of tumors in rats was 25% following both routes of administration. None of the control rats developed tumors. Tumor incidence in mice was 60% after s.c. treatment and 31% following p.o. treatment. However, some of the control mice also developed tumors. Carcinogenic activity appears to depend on the presence of the carbamyl moiety in the β -position of the naphthyl group, since α -sevin is noncarcinogenic.

- 1290 CARCINOGENICITY OF THE PESTICIDES SEVIN, MANEB, CIRAM AND CINEB. (Rus.) Andrianova, M. M. (Acad. Med. Moscow, U.S.S.R.) and I. V. Alekseeva. *Vop Pitani* 29(6):71-74, 1970.

The carcinogenicity of sevin, maneb, ciram and cineb was tested by p.o. and s.c. administration to randombred rats. Each pesticide was given p.o. as a suspension in water (30 mg/kg sevin, 335 mg/kg maneb, 70 mg/kg ciram or 285 mg/kg cineb) twice a wk for 22 months to experimental groups of 60 rats each. S.C. treatment consisted in a hip implant of paraffin pills containing 20 mg sevin, 12.5 mg maneb, 15 mg ciram or 20 mg cineb to 4 groups of 48 rats each. Tumors were noticed 22 months after the beginning of the experiment in all of the experimental groups. Sevin (p.o.) induced tumors in 4 of 10 rats (2 fibrosarcomas of the right hip, 1 polymorphous cell sarcoma of the mediastinum and 1 osteosarcoma); s.c. treatment resulted in fibrosarcomas in 2 of 10 rats. Maneb treatment (p.o.) induced tumors in 2 of 10 rats (1 mammary gland carcinoma and 1 rhabdomyosarcoma of the left hip), and s.c. treatment resulted in 1 carcinoma of the thyroid, 1 fibrosarcoma in the neck region and 1 sarcoma of the mediastinum in 3 of 4 rats. Ciram administration (p.o.) produced tumors in 4 of 10 rats (2 malignant hepatomas, 1 subcutaneous fibrosarcoma and 1 subcutaneous polymorphous cell sarcoma in the spinal and neck region, resp. when applied s.c., tumors occurred in 3 of 10 rats (1 hepatoma, 1 lymphosarcoma of the colon and 1 s.c. fibrosarcoma in the hip region). Cineb given p.o. produced tumors in 2 of 10 rats (1 adenocarcinoma of the colon and 1 intestinal lymphosarcoma), and with s.c. treatment 4 of 10 rats developed tumors (1 hepatoma, 1 fibrosarcoma of the gastric wall, 1 subcutaneous rhabdomyosarcoma of the hip and 1 spindle cell sarcoma of the right anterior limb). Of the 48 control animals 1 of 46 developed fibrosarcoma 11 months after the beginning of the experiment. No tumor development occurred at the site of implantation of the pesticides indicating that these pesticides exhibit a general carcinogenic action in rats.

- 1291 CARCINOGENICITY OF ISOSTERS OF EPOXIDES AND LACTONES: AZIRIDINE ETHANOL, PROPANE SULFONE, AND RELATED COMPOUNDS. (E.) Van Duuren,

B. L. (New York U. Med. Ctr., New York, N. Y.), S. Melchionne, R. Blair, B. M. Goldschmidt and C. Katz. *J Nat Cancer Inst* 46(1):143-149, 1971.

The carcinogenicity of low molecular wt compounds including epoxides, their nitrogen or sulfur analogs, a polymeric aldehyde, and an acetal were investigated in mice. Mice were maintained on a lifetime (63-93 wk) regimen of s.c. injections of the test agents. Propane sultone (1-propanesulfonic acid-3-hydroxy- γ -sultone) and aziridine ethanol (β -hydroxy-1-ethyl-aziridine) induced sarcomas at the injection site when administered in doses of 0.3 mg/0.05 ml distilled water. Twenty-one of 30 mice injected with propane sultone developed 12 sarcomas, 1 carcinoma, 7 adenocanthomas and 1 papilloma. Ten of 30 mice given aziridine ethanol developed sarcomas. The compounds 3,4-epoxysulfolane, 1,2-epoxybutyronitrile, 3,4-dihydroxy-3-cyclobutene-1,2-dione, ethyl-2,3-epoxybutyrate, tetramethyl-1,3-cyclobutanedione, perchloro-2-cyclobutene-1-one, and polymeric dialdehyde induced less than 3 tumors at the sites of their injections. The following compounds failed to induce tumors: 3-sulfolene, 3,4-epoxybutanal diethylacetal, 5,6-epoxyhexanal diethylacetal, and N,N-dimethylformamide dimethylacetal.

1292 AVIDITY OF FOLIC ACID FOR CARCINOGENIC METAL IONS, ALUMINIUM(III), CHROMIUM(III), BERYLLIUM(II), LEAD(II) AND URANIUM(VI). (E.) Nayan, R. (Chem. Lab., U. Allahabad, India) and A. K. Dey. *Z Naturforsch* 256(12):1453-1457, 1970.

The chelate formation of folic acid with the carcinogenic metal ions, aluminum (III), chromium (III), beryllium (II), lead (II) and uranium (VI) has been studied with the Bjerrum-Calvin pH-titration technique. Chelates at biological pH were formed only with the phenolic form of folic acid; no sharp change was seen in the shape of the chelate-formation curves at different ionic strengths, suggesting that the various species coexist in solution.

1293 DEVELOPMENT OF HEPATIC TUMORS IN RATS FOLLOWING INGESTION OF *SENECIO LONGILOBUS*. (E.) Harris, P. N. (Eli Lilly Co., Greenfield, Ind.) and K. K. Chen. *Cancer Res* 30(12):2881-2886, 1970.

The effects of prolonged administration of dried *Senecio longilobus* (SL) in the diet of rats on the development of hepatic tumors and associated manifestations is reported. In rats receiving a continuous diet of 0.75% SL, deaths began to occur rapidly after 1 month with longest survival time being 131 days; at 0.5% concentrations survival times increased somewhat with 4 rats living more than 200 days. Of 31 rats receiving 0.5% concentrations for 1 month followed by a 2-wk SL-free diet for a period of 1 yr and of those given 0.5% Senecio diet for 1 wk alternated with 1 wk SL-free diet for 1 yr, 22 survived from 419-657 days. Rats with a survival time of less than 3 months demonstrated pulmonary edema sometimes associated with hydrothorax or ascites, pneumonia, pulmonary congestion and intra-alveolar hemorrhage, and epithelial proliferation only occasionally. With

increasing age, the number and foci of proliferation increased to 7% for the entire group and was 31% for survivors after 300 days. Incidence of pulmonary arteritis was 50% in rats dying before 100 days, 20% between 100 and 300 days, and 6% in those dying after 300 days, with thrombosis of small vessels occurring commonly. Albumin/globulin ratios determined in 9 rats were reversed and liver cell necrosis was observed in nearly 20% of the rats that died during the first 3 months; after short exposure to SL, some livers were dark, reddish-brown, friable and of normal size. Later they diminished in size and demonstrated hypertrophic parenchymal cells and nuclei with regeneration leading to formation of nodules suggestive of neoplasm greater than 1 cm diameter and bile duct proliferation with formation of cholangiocystomas. After 428 to 657 days, four had hepatocarcinomas with central necrosis proliferating to portal veins and branches of the pulmonary arteries.

1294 THE EFFECT OF CHRONIC ESTROGENIC STIMULATION ON THE SQUIRREL MONKEY CERVICAL EPITHELIUM. (E.) Graham, C. E. (Yerkes Reg. Primate Res. Ctr., Emory U., Atlanta, Ga.) and S. L. Manocha. *Virchow Arch Zellpath* 7(2-3):147-156, 1971.

Estradiol benzoate implantation in squirrel monkeys was used to study epidermization of the cervical epithelium in response to chronic estrogenic stimulation. Stratified squamous epithelium of the vagina and cervix became clearly demarcated from columnar epithelium with no essential difference noted in response to 10% or 95% estradiol benzoate pellets. Stimulation with pellets of 100% diethylstilbestrol for periods of 5 or more months resulted in isolated foci of varying size of partially cornified stratified epithelium compared to control animals which demonstrated only occasional small islands of apparently isolated stratified cells. No areas of epithelium could be recognized as intermediate in morphology between normal columnar and normal stratified epithelium. Glycogen content was most prominent in the intermediate layer of the cervical stratified epithelium and became depleted after treatment with diethylstilbestrol, whereas in controls this glycogen content increased. The activity of phosphorylases, alcohol dehydrogenases and simple esterases was enhanced in the experimental animals, while 6-phosphogluconate dehydrogenase and ATPase were somewhat reduced; no apparent changes in alkaline or acid phosphatase reactions were observed in either experimental or control animals. New squamous cells appeared to be an outgrowth from the stratified squamous epithelium at the squamocolumnar junction, rather than from squamous metaplasia of columnar cells.

1295 THE SYNERGISM BETWEEN RADIATION AND ESTROGEN IN THE PRODUCTION OF MAMMARY CANCER IN THE RAT. (E.) Segaloff, A. (Alton Ochsner Med. Found., New Orleans, La.) and W. S. Maxfield. *Cancer Res* 31(2):166-168, 1971.

Rats implanted with pellets containing estrogen (25% diethylstilbesterol, 75% cholesterol) and ir-

radiated with 800 r to the center of the mammary chain developed more mammary carcinomas after a shorter latency than rats given estrogen alone, or irradiation alone. Twelve of 14 rats given estrogen and radiation developed a total of 78 palpable mammary tumors on the irradiated mammary chain; the first tumor appeared 18 wk after irradiation. The mammary chain which was shielded from radiation in estrogen-treated rats developed a total of 17 tumors after 29 wk latency. Rats which were given estrogen pellets only, without irradiation, developed mammary tumors in 15/16 cases; the total number of tumors developed by this group was 54, and the latency was 20 wk. Rats given radiation alone, without estrogen, developed tumors in 8/11 cases; the total number of tumors developed by this group was 12 and the latency was 75 wk. Apparently, a synergism exists between the actions of X-irradiation and estrogen treatment in the rat mammary carcinogenesis.

- 1296 ULTRASTRUCTURAL ALTERATIONS WITHIN HYPERPLASTIC LIVER NODULES INDUCED BY ETHIONINE. (E.) Merkow, L. P. (W. H. Singer Mem. Res. Inst., Allegheny Gen. Hosp., Pittsburgh, Pa.), S. M. Epstein, M. Slifkin, E. Farber and M. Pardo. *Cancer Res* 31(2):174-178, 1971.

The effect of ethionine-induced liver hyperplasia on cellular ultrastructure was studied in male Wistar rats by electron microscopy. Examination of cells from fasted animals with ethionine-induced nodules showed a marked clustering and aggregation of the smooth endoplasmic reticulum with corresponding diminution in rough endoplasmic reticulum which was closely apposed to the mitochondria. In addition, multivesicular bodies in close proximity to both the Golgi complex and the clusters of smooth endoplasmic reticulum were observed; these changes were remarkably similar both within any one nodule and from one hyperplastic liver nodule to another. Nonnodular liver adjacent to hyperplastic liver nodules showed a remarkable preservation of subcellular organelles and organization in both fed and fasted animals. Nodular cells obtained from fed rats maintained both normal intra- and intercellular relationships. The cytostructural alterations appear to represent a specific set of subcellular reaction patterns confined to the hyperplastic liver nodule, which differs markedly from that noted in hepatocellular carcinoma cells.

- 1297 MITOTIC, CHROMOSOMAL, AND NUCLEOLAR ALTERATIONS INDUCED BY THIOACETAMIDE IN RELATION TO THE MITOTIC CYCLE AFTER PARTIAL HEPATECTOMY. (E.) Mironescu, S. (Inst. Endocr., Bucharest, Rumania) and M. Ciovirnache. *J Nat Cancer Inst* 46(1):49-61, 1971.

Induction of mitotic, chromosomal and nucleolar alterations within the mitotic cycle by thioacetamide (150 mg/kg) after partial hepatectomy was studied in male Wistar rats by means of tritiated thymidine. Almost all hepatocytes proliferated after partial hepatectomy at a 90-95% level, with 8% labeling in DNA synthesis during the 22nd hr followed by a steady flux of cells through synthe-

sis at a rate of 3-4% per hour. Thioacetamide did not increase the number of cells entering DNA synthesis nor did it raise the low incidence of abnormal nucleoli during the first 12 hr. When given at later intervals, increased numbers of nuclei with "aniso" nucleoli were induced and reached a peak value when the carcinogen was given 18 hr after partial liver removal. The earliest detectable alteration induced by the carcinogen was nucleolar hypertrophy, and Colcemid and vinblastine effectively blocked most cells entering mitosis 25-31 hr after partial hepatectomy at metaphase. The apparent S-phase dependence of thioacetamide chromosomal aberrations suggests that the damaging action is exercised on cells already in S and although morphologically similar to those induced by other agents, the mechanism of action is not identified.

- 1298 THE BINDING OF N-HYDROXY-2-ACETYLAMINO-FLUORENE TO REPLICATING AND NONREPLICATING DNA IN RAT LIVER. (E.) Jackson, C. D. (U. Tennessee Med. Unit, Memphis) and C. C. Irving. *Chem Biol Interact* 2(3):261-265, 1970.

Male rats were given i.p. injections of ^{14}C -labeled N-hydroxy-2-acetylaminofluorene and 250 μC of tritiated 5-bromo-2'-deoxyuridine in order to determine whether the former compound was bound to rat liver DNA which is replicating or to nonreplicating DNA. Newly replicated DNA, which had incorporated ^3H -5-bromo-2'-deoxyuridine, was found to band on CsCl density gradients at an average density greater than that of the bulk of the DNA. The distribution of the carcinogen N-hydroxy-2-acetylaminofluorene which was bound to DNA *in vivo* was coincident with the distribution of the bulk of the DNA, indicating that this carcinogen did not bind to DNA exclusively during replication.

- 1299 REGRESSION AND PERSISTENCE OF HYPERPLASTIC HEPATIC NODULES INDUCED BY N-2-FLUORENYL-ACETAMIDE AND THEIR RELATIONSHIP TO HEPATOCARCINOMAS. (E.) Teebor, G. W. (New York U. Sch. Med., New York, N. Y.) and F. F. Becker. *Cancer Res* 31(1):1-1971.

The development of hyperplastic nodules and hepatic carcinomas in the livers of rats fed N-2-fluorenyl-acetamide (2-FAA) was investigated in the belief that the nodules represent an early stage of malignant change. Male rats were given a diet containing 0.02% 2-FAA for three 3-wk periods; another group of rats was given the 2-FAA diet for four 3-wk periods. At the end of the 3 cycle feeding period, 45 of 50 rats had developed nodules on the surface of the liver; 2 months after cessation of 2-FAA feeding, 12 of 25 rats showed nodules, and by 6 months after 2-FAA feeding, only 2 of 25 rats had nodules. Only 1 of 25 rats fed with 2-FAA in the 3-cycle feeding regimen developed hepatocellular carcinoma. At the end of 4-cycle feeding regimen, 75 of 80 rats had developed nodules; at 6 months after the cessation of the 4-cycle feeding regimen, 26 of 37 rats showed nodules, and 12 months 14 of 23 rats had developed hepatomas.

which never developed nodules, and rats in which nodules regressed completely, never developed hepatomas. The results appeared to suggest that a linear relationship exists between the hyperplastic nodule and hepatocellular carcinoma development.

- 1300 DISORGANIZATION OF MOUSE BLADDER EPITHELIUM INDUCED BY 2-ACETYLAMINOFLUORENE AND 4-ETHYLSULFONYLNAPHTHALENE-1-SULFONAMIDE. (E.) Levi, P. E. (Dept. Exp. Path. Cancer Res., Leeds, England), J. C. Knowles, D. M. Cowen, M. Wood and E. H. Cooper. *J Nat Cancer Inst* 46(2):337-352, 1971.

Modification of the bladder epithelium of female A x IF mice fed 4-ethylsulfonylnaphthalene-1-sulfonamide (ENS) or 2-acetylaminofluorene (AAF) was studied by the use of electron and light microscopy. Bladder epithelium of mice fed AAF for 4-12 wk showed an increase of 3 to 5 cell layers with mitotic activity, DNA measurements of nuclei and distribution of alkaline phosphatase were similar to that in the controls. Two main types of modification of the ultrastructure that were observed in these cells were that the cytoplasm of the large surface cells had few fusiform vesicles, and the lysosomes were often surrounded by a series of concentric, double membranes. After 20 wk, the membrane whorls regressed, the mitochondria were abnormal, and the unit membrane of the surface cells was asymmetric. The response to ENS after 4 wk was crystalluria, and after 8 wk large concretions of calcium phosphate and oxalate were present in the bladder. Pronounced hyperplasia 6-8 cell layers thick occurred with the percentage of cells in mitosis varying considerably from one animal to another, ranging from the normal 0.01% to about 10%, and marked inflammatory changes in connective tissue with edema and extensive infiltration of polymorphonuclear leukocytes and lymphocytes occurred. Dedifferentiation and a loss of alkaline phosphatase activity occurred after 8 wk, while the ultrastructure showed a striking loss of characteristic organelles with formation of dark, osmiophilic inclusions which eventually destroyed the mitochondria. Return to a normal diet for 8 wk resulted in loss of crystalluria and a virtually normal histological appearance and normal alkaline phosphatase distribution.

- 1301 DIFFERENCES IN THE BINDING OF 2-ACETYLAMINOFLUORENE AND ITS N-HYDROXY METABOLITE TO LIVER NUCLEIC ACIDS OF MALE AND FEMALE RATS. (E.) Irving, C. C. (VA Hosp., U. Tennessee, Memphis) and R. A. Veazey. *Cancer Res* 31(1):19-22, 1971.

Covalent binding of the carcinogens 2-acetylaminofluorene (AAF) and N-hydroxy-acetylaminofluorene (N-hydroxy-AAF) to liver nucleic acids of male and female rats was investigated in order to explain the observation that male rats are more prone to induction of liver cancer by these compounds than are female rats. Rats were given s.c. injections of ¹⁴C-9-labeled AAF or N-hydroxy-AAF in amounts of 30 mg/kg body wt 16 hr before sacrifice, and tRNA, rRNA and DNA were isolated in liver preparations. Livers of male rats given AAF were able to bind

123 picomoles of the compound/mg tRNA and 42-44 picomoles/mg rRNA. Females were able to bind 71 picomoles AAF/mg tRNA and 26-29 picomoles/mg rRNA. When N-hydroxy-AAF was injected, the amounts which were bound to nucleic acids were 160 picomoles/mg tRNA for males and 55 picomoles/mg rRNA for females. No sex differences were found in the binding of total radioactivity to liver DNA after injection of either compound, and amounts of compound able to bind to DNA did not differ by more than 3 picomoles between males and females. Seventy-two percent of the fluorene residues which were bound to rRNA, and 37% of those which were bound to DNA retained the N-acetyl group in males, while in females 33% of the fluorene residues which were bound to rRNA and only 7% of those which were bound to DNA retained the N-acetyl group. The mechanisms of N-hydroxy-AAF metabolic activation as well as the amounts of AAF which bind to liver nucleic acids seemed to show sex differences in rats.

- 1302 STUDIES OF EXPERIMENTAL BLADDER CARCINOMA IN FISCHER 344 FEMALE RATS: I. INDUCTION OF TUMORS WITH DIET LOW IN VITAMIN B₆ CONTAINING N-2-FLUORENYLACETAMIDE AFTER SINGLE DOSE OF CYCLOPHOSPHAMIDE. (E) Koss, L. G. (Sinai Hosp. Baltimore, Md.) and P. Lavin. *J Nat Cancer Inst* 46(3):585-595, 1971.

All 17 rats in a group given 100-200 mg/kg cyclophosphamide and placed on a diet deficient in pyridoxine and containing 600 mg/kg N-2-fluorenylacetamide (FAA) developed carcinoma of the urinary bladder; in 16 cases, the tumors were invasive. Carcinomas appeared beginning 6.75 months after initiation of the carcinogenic diet. Three of 5 rats given the carcinogenic diet without cyclophosphamide developed carcinoma of the bladder, 2 of which were invasive; the earliest tumor appeared 8.5 months after initiation of the carcinogenic diet. None of the rats given a pyridoxine-deficient diet alone developed bladder tumors, and none of the rats given cyclophosphamide with a normal diet developed bladder tumors. Carcinoma *in situ* was not observed to precede the development of invasive carcinomas, although the epithelium of the bladder adjacent to already-developed carcinomas showed carcinoma *in situ*. During the first 6 months after initiation of the carcinogenic diet, rats given cyclophosphamide showed epithelial hyperplasia in the bladder. Papillomas developed after 4 months on the carcinogenic diet, and after 6 months squamous metaplasia were observed. Tumor formation was not influenced by dosage of cyclophosphamide or by the timing of the start of the carcinogenic diet. Synergism between cyclophosphamide and the known immunosuppressive effects of FAA may have been active in the production of bladder carcinoma in the carcinogenic diet group.

- 1303 THE EFFECT OF L-ASPARAGINASE ON MITOTIC ACTIVITY DURING N-2-FLUORENYLACETAMIDE HEPATOCARCINOGENESIS: SUBPOPULATIONS OF NODULAR CELLS. (E.) Becker, F. F. (New York U. Sch. Med., New York) and K. M. Klein. *Cancer Res* 31(2):169-173, 1971.

Administration of L-asparaginase (100 IU/kg) to 70%-hepatectomized rats fed for 3 wk on a diet of 0.06% N-2-fluorenylacetylamide (2-FAA) diminished the increased mitotic activity of liver cells and hepatic nodules which followed hepatectomy. At the end of 4 cycles of 2-FAA feeding, livers of rats showed a 75% conversion to hyperplastic nodules. Following hepatectomy, mitotic activity measured by ^3H -thymidine incorporation increased 44-fold in liver tissue apparently due to increased DNA synthesis in hepatocytes. Seventy percent hepatectomy increased ^3H -thymidine incorporation 100-fold in hyperplastic hepatic nodules. L-asparaginase completely inhibited ^3H -thymidine incorporation in normal hepatocytes after hepatectomy, and decreased by 80% thymidine incorporation in nodular hepatocytes. L-asparaginase delayed the mitotic cycle of normal hepatocytes by 10-12 hr. Aggregates of cells within the hyperplastic nodules were found to resist the effects of L-asparaginase.

- 1304 STUDIES OF EXPERIMENTAL BLADDER CARCINOMA IN FISCHER 344 FEMALE RATS: II. CHARACTERIZATION OF 3 CELL LINES DERIVED FROM INDUCED URINARY BLADDER CARCINOMAS. (E.) Lavin, P. (Dept. Biol., Massachusetts Inst. Tech., Cambridge) and L. G. Koss. *J Nat Cancer Inst* 46(3):597-614, 1971.

Two epithelial and 1 fibroblastic cell lines derived from urinary bladder squamous carcinomas which had been induced in rats by N-2-fluorenylacetylamide and cyclophosphamide were maintained *in vitro* through multiple passages. In one of the epithelial cell lines (BC₆) fibroblasts comprised part of the culture in early passages; however fibroblasts were supplanted by epithelial cells after the third passage. Both epithelial cell lines produced carcinomas in the cheek pouches of hamsters and in newborn rats; tumors were undifferentiated carcinomas and well-differentiated squamous carcinomas. Fibroblast cells did not produce tumors in hamsters or rats. Although the fibroblast line was initially diploid, all three lines became 50-80% tetraploid after 15-18 passages. Marker chromosomes were common in the epithelial cell lines. Electron microscopy showed that 1 of the epithelial cell lines was marked by cytoplasmic tonofibrils forming numerous microvilli; these cells had abundant desmosomes and many free ribosomes. Cells in this line showed differentiation *in vitro* similar to that observed in keratinizing squamous epithelium *in vivo*; however, fully keratinized cells were not seen. Many degenerating cells in this line had an electron-dense membrane measuring 175-200 Å located beneath the plasmalemma and apparently fused to its inner leaflet. Numerous intracytoplasmic vesicles were seen resembling those seen in superficial cells of the rat urinary bladder; vesicles were seen in epithelial cells of one line *in vivo* and in cheek pouch tumors produced by these cells in hamsters. The other epithelial line and the fibroblastic cell line were morphologically different from the differentiating epithelial cell line, having few microvilli and lacking cytoplasmic vesicles and may have originated from cells of a different type.

- 1305 STUDIES ON LIVER PLASMA MEMBRANES OF RATS FED N-2-FLUORENYLACETAMIDE. (E.)

Chandrasekhara, N. (Central Food Technol. Res. Inst. Mysore, India) and K. A. Narayan. *Cancer Res* 30(12):2876-2880, 1970.

This study was designed to investigate the lipid composition of liver plasma membranes of male weanling rats fed N-2-fluorenylacetylamide (0.05 or 0.3 g/kg diet) using marker enzymes, 5'-nucleotidase and Mg^{2+} -Na-K-ATPase. Specific activities of 5'-nucleotidase and ATPase were lower in liver homogenates of N-2-fluorenylacetylamide-fed rats than in normal liver homogenates. Membranes from both preneoplastic and neoplastic livers had markedly low 5'-nucleotidase activity but showed no change in ATPase activity. Glucose 6-phosphatase activity was quite low in membranes from all groups while there was a marked increase in the percentage of total phospholipids in membranes from both preneoplastic and neoplastic livers ranging from 71.4-79.3% compared to 59.3% in normal membranes and only a nominal increase in liver homogenates ranging from 60.3-66.5% compared to 57.7% in homogenates from normal livers. Carcinogenesis did not change the percentage of cholesterol in membranes with a slight increase noted in the carcinogenic liver homogenates from 6.8% to 8.0% compared to 5.5% for normal liver homogenates. A significant increase ($p < 0.05$) in total polyunsaturated fatty acids and a corresponding decrease in total saturated fatty acids was seen in membranes from N-2-fluorenylacetylamide-fed rats compared to fatty acid composition in membranes from normal rats. The floating layer was increased 5- to 10-fold in carcinogenic liver homogenates and was characterized by fairly high activities of 5'-nucleotidase and ATPase and low activities of glucose-6-phosphatase and succinic dehydrogenase with lipid:protein ratios higher and phospholipid fraction lower compared to normal liver homogenates. Increased yield of plasma membranes and floating fractions may be due to the presence of increased quantities of membrane precursors.

- 1306 INSTABILITY OF FLUORENYLAMINE-SUBSTITUTED POLYNUCLEOTIDES: LOSS OF CARCINOGENIC ACTIVITY IN THE PRODUCTION OF AN ALTERED NUCLEIC ACID. (E.) King, C. M. (Michael Reese Hosp. Med. Ctr., Chicago, Ill.) and B. Phillips. *Chem Biol Interact* 2(3):267-271, 1970.

The instability of fluorenylamine-substituted rat liver RNA, calf thymus DNA and poly-G on incubation in 0.5 M Tris-HCl at physiological temperature and pH were studied. Substituted rat liver ribosomal RNA exhibited the greatest instability, while substituted calf thymus DNA appeared to be the most stable. The guanylic acid content of substituted sRNA at the start of incubation showed a 19% loss compared to control preparations of unmodified sRNA; no restoration of guanylic acid content occurred after incubation despite a 78% loss of absorbance at 320 mμ, which indicated a loss of fluorene residues.

dues. Loss of fluorene residues from nucleic acid adducts may be due to preferential release of fluorenylamine substituents, and lack of restoration of guanylic acid content with release of fluorene residues may represent a mechanism by which release of bound carcinogen damages nucleic acid. The adenine, cytosine or uracil contents of sRNA were not altered by the reagent which was used to make the fluorenylamine derivatives or by the incubation conditions.

- 1307 CELL PROLIFERATION IN THE THYMUS AFTER REPEATED SUBCUTANEOUS ADMINISTRATION OF FREUND'S ADJUVANT. (Ger.) Backmann, B. (Path. Inst. U. Munster, Germany) and K. Morgenroth, Jr. *Verhandl Deutsch Ges Path* 54:243-247, 1970.

Repeated s.c. injections of Freund adjuvant in the neck of a guinea pig produced an interstitial pulmonary fibrosis in the presence of an interstitial pneumonia of the plasmacellular histiocyte type. No other organs revealed any cellular reactions, except the thymus, in which there was proliferation of the lymphoid and reticular cells. It was possible to measure by autoradiography the proliferation of the lymphoid cells and of the small and large reticular cells, using as a measure of activity the ^3H index 1 hr after the administration of ^3H -thymidine. The lymphoid cell index rose from 1.9% (in controls) to 5.7% 11 days after the administration of the adjuvant and to 6.4% 22 days after the adjuvant. Proliferation increase in small reticular cells was 1.4 times the control value after 11 days, and 4.2 times greater 22 days after the adjuvant. The large reticular cells showed a lesser activity by an increase of only 1.2-fold after 11 days and 1.5-fold after 22 days. The selective immunological reaction of the thymus and the lungs is probably explainable by the mainly lymphogenic transport of the antigen reactive substances of Freund adjuvant.

- 1308 AFLATOXIN STRUCTURE AND HEPATOCARCINOGENICITY IN RAINBOW TROUT (*SALMO GAIARDNERI*). (E.) Ayres, J. L. (Cotton Producers Ass., Atlanta, Ga.), D. J. Lee, J. H. Wales and R. O. Sinnhuber. *J Nat Cancer Inst* 46(3):461-564, 1971.

One yr after introduction of dietary aflatoxin B_1 (4 parts per billion, ppb) 25% of the rainbow trout developed hepatomas compared to 0% of the controls not given the carcinogen. At 16 months the hepatoma incidence in these fish was 35%. Eight ppb of aflatoxin B_1 produced tumors in 70% of the fish at 1 yr, while 4 ppb aflatoxin B_1 together with 4 ppb aflatoxin B_2 gave a 43% tumor incidence at 1 yr (70% at 16 months). Twenty ppb aflatoxin B_1 caused a tumor incidence of 78% in 1 yr; however, the same amount of aflatoxin B_2 produced a tumor incidence of only 5%. Aflatoxin G_1 (20 ppb) caused tumors in 5% of fish, while aflatoxin G_2 , 7-ethoxy-4-methylcoumarin, and isobergaptene (all at 20 ppb) produced no tumors in trout. Tetrahydrodeoxoaflatoxin B_1 (20 ppb) resulted in a 1% tumor incidence, and 5,7-dimethoxycyclopentenone-(2,3-c)coumarin produced no tumors. These results suggested that the carcinogen-

icity of aflatoxin B_1 depended on the bifunctional activity of the molecule with a requirement for both the dihydrofurofuran ring system and the unsaturated δ -lactone moieties.

- 1309 SPECIES DIFFERENCES IN THE *IN VITRO* METABOLISM OF AFLATOXIN B_1 . (E.) Bassir, O. (Biochem Dept., U. Ibadan, Nigeria) and P. O. Emafo. *FEBS Letters* 12(5):273-275, 1971.

The *in vitro* metabolism of aflatoxin B_1 was investigated in liver microsomes prepared from toad, lizard, duck, and cockerel. Liver microsomes and the soluble fraction of the liver were incubated with 160 nmoles of aflatoxin B_1 . Lizard and toad liver microsomes, but not duck or cockerel microsomes, metabolized aflatoxin B_1 into a blue-violet fluorescing substance of R_f 0.20 in a 10% acetone in chloroform solvent system. This metabolite was identified as aflatoxin M_1 . The presence of the aflatoxin M_1 metabolite in lizard and toad liver, and its absence in duck and cockerel liver, indicated a species difference in the metabolism of aflatoxin B_1 by hydroxylation to aflatoxin M_1 . Another metabolite of zero R_f value in the same solvent system was produced by all the animal species studied. Of the total aflatoxin B_1 in the incubation media, 98-99% was metabolized in the first 1 hr of incubation. In duck and cockerel, differences in the metabolism of aflatoxin B_1 were not pronounced, suggesting that factors other than metabolism account for differences in susceptibility in these species.

- 1310 AFLATOXIN P_1 : A NEW AFLATOXIN METABOLITE IN MONKEYS. (E.) Dalezios, J. (Dept. Nutr. Food Sci., Massachusetts Inst. Tech., Cambridge), G. N. Wogan and S. M. Weinreb. *Science* 171(3971):584-585, 1971.

A new metabolite of aflatoxin B_1 was isolated from the urine of rhesus monkeys which had been administered aflatoxin B_1 and was designated aflatoxin P_1 . Aflatoxin P_1 was the metabolic product of O-demethylation of aflatoxin B_1 ; 50% of it was present in the monkey urine as the glucuronide, 10% as the sulfate and 3% as the phenol. It appears to be the major urinary metabolite of aflatoxin B_1 and represents 20% of the excreted form of a single dose within 24 hr after injection.

- 1311 EFFECT OF AFLATOXIN ON CARBOHYDRATE METABOLISM IN CHICK LIVER. (E.) Shankaran, R. (Dept. Psychiat., U. British Columbia, Vancouver, Canada), H. G. Raj and T. A. Venkitesubramanian. *Enzymologia* 39(6):371-378, 1970.

Carbohydrate metabolizing enzymes were assayed in the livers of male chicks given i.p. injections of aflatoxin B (2.7 mg/kg) 48 hr before sacrifice. A significant decrease in the activity of uridine diphosphate glucose-glycogen transglucosylase was found in the treated birds. Control values for specific glycogen synthetase activity were 4.05 U/g

protein, while glycogen synthetase activity in aflatoxin-treated birds was 0.44 U/g. Glycogen phosphorylase specific activity was decreased from 155 U/g in controls to 62 U/g in treated chicks. Control and aflatoxin-treated values for phosphoglucose mutase specific activity were 854 and 670 U/g, resp. Glucose-6-phosphatase specific activity in controls and aflatoxin-treated birds was 40 and 8.16 U/g, resp. Activity of hexose monophosphate dehydrogenases were elevated 3-fold in aflatoxin-treated birds over controls.

- 1312 *IN VITRO* MALIGNANT TRANSFORMATION OF CELLS DERIVED FROM RAT LIVER BY MEANS OF AFLATOXIN B₁. (E.) Toyoshima, K. (Nara Med. Coll., Japan), Y. Hiasa, N. Ito and Y. Tsubura. *Carcinogenesis* 61(6):557-561, 1970.

Transformation of rat liver cells by aflatoxin B₁ was investigated in cells cultivated through 12 subcultures for 161 days and exposed to aflatoxin B₁ (0.01-10 ppm) for 5-7 days. Morphological transformation was observed in all cell cultures exposed to aflatoxin B₁ and was most conspicuous at 2 wk after exposure. Approximately $4-5 \times 10^4$ transformed cells which were back-transplanted into newborn rats produced fibrosarcomas in 10 of 39 rats after latency periods of 75-187 days. Aflatoxin B₁ appeared to be a relatively potent carcinogen *in vitro* and able to cause moderate transformation in varying concentrations.

- 1313 INHIBITORY ACTION OF PREGNENOLONE ON LIVER CARCINOGENESIS AND ENHANCEMENT OF THE DEVELOPMENT OF TUMORS IN THE INTERSTITIAL TESTICULAR GLAND IN RATS TREATED WITH PARA-DIMETHYLAMINOAZOBENZENE (DAB). (Fr.) Lacassagne, A. (Fac. Med. Paris, France), M. F. Jayle and L. Hurst. *C R Acad Sci* 272(1):174-177, 1971.

Comparison of the effects of various C-21 steroids in the production of hepatic carcinomas in male rats given DAB daily (600 mg/kg) has demonstrated that progesterone (Δ_4 -P) and 17 α -hydroxyprogesterone (17-OH- Δ_4 -P) retarded the process of cancerization of the liver by DAB, and that pregnenolone (Δ_5 -P) and 17 α -hydroxypregnenolone (17-OH- Δ_5 -P) inhibited it completely. One of 3 rats given progesterone developed hepatoma, while 3 of 6 rats given 17-OH- Δ_4 -P developed hepatomas; none of the 20 rats given pregnenolone or 17-OH- Δ_5 -P developed hepatomas. In addition, early-stage tumors of the Leydig cells were found in 1 rat receiving Δ_5 or 17-OH- Δ_5 -P with DAB. The development of the Leydig cell tumors may have been influenced by the hypothalamic area where the hypophyseal tropic hormone is elaborated.

- 1314 THE EFFECT OF THE HORMONAL BALANCE ON *p*-DIMETHYLAMINOAZOBENZENE HEPATOCARCINOGENESIS IN RATS. (Rus.) Podzey, L. K. (P. A. Herzen Inst. Oncol. Moscow, U.S.S.R.). *Russkaya Fiziol Eksp Ter* 14(6):32-36, 1970.

p-Dimethylaminoazobenzene (DAB) hepatocarcinogenesis in conditions of castration, synestrol or testosterone treatment was investigated in male and female Wistar rats maintained on a rice and carrot diet. The following experimental groups were used: I) 46 males and 50 females received no treatment and were maintained on a normal diet; II) 47 males and 46 females were maintained on a rice and carrot diet; III) 47 males and 46 females were on the group II diet and treated with DAB (6 mg p.o. daily for 10 months); IV) 55 males and 54 females were treated with DAB as above following castration; V) 59 males and 63 females were treated the same as group IV and given synestrol (s.c. implant of 30 mg synestrol followed 1 month later by s.c. injections of 0.05 mg synestrol on alternate days for the duration of the experimental period); VI) 55 males and 56 females were treated the same as group V but received testosterone instead of synestrol. Group V showed the most severe DAB-induced effects with hepatomas occurring in 17% of the female rats and in 22% of the male rats after latency periods of 5-6 months. Group VI had the lowest tumor incidence (3.5-3.6%) after a latency period of 9-10 months. Group IV had a 5.5% tumor incidence in females and 27% tumor incidence in males after 8-9 months of latency. Group III had a tumor incidence of 10.5% in females and 6.7% in male rats after 6 and 9 months of latency, resp. No tumors were observed in Groups I or II.

- 1315 THE EFFECT OF THE ADMINISTRATION OF *N,N*-DIMETHYL-4-AMINOAZOBENZENE (DAB) ON THE ACTIVITY OF DAB-REDUCTASE AND NADPH-CYTOCHROME *c* REDUCTASE. (E.) Ketterer, B. (Middlesex Hosp. Med. Sch., London, England), P. Ross-Mansell and H. Davidson. *Chem Biol Interact* 2(3):183-194, 1970.

The effect of *N,N*-dimethyl-4-aminoazobenzene (DAB) on the activity and cellular distribution of DAB-reductase and NADPH-cytochrome *c* reductase was investigated in male rats given 50 mg DAB by i.p. injection or 0.06% DAB in the diet. One hr after injection of DAB, a significant decrease in DAB-reductase was observed in rat livers; DAB-reductase values for untreated controls were 236 μ moles DAB reduced/min/100 mg microsomal protein, while in rats injected with DAB, reductase values 1 hr postinjection were 111 μ moles/min/100 mg. About 6-16 hr postinjection, DAB-reductase values in treated rats reached their nadir (0 at 6 hr, 63 μ moles/min/100 mg at 16 hr); DAB-reductase values recovered steadily after 16 hr. In chronic DAB feeding studies, it was found that the smooth microsomes in normals contained more than twice the concentrations of DAB-reductase than the rough microsomes. The decrease in DAB-reductase activity caused by DAB had the effect of equalizing the concentrations of DAB-reductase in the smooth and rough microsomal fractions, with the rough microsomes having slightly higher concentrations of DAB-reductase than the smooth. The addition of flavin adenine nucleotide to the assay mixture only increased DAB-reductase activity from 63 to 96 μ mol/min/100 mg in treated animals, indicating that reduced DAB-reductase activity was not due to reduced levels of flavin. DAB had no effect on NADPH-cytochrome *c* activity which had the same distribution

pattern as the residual DAB-reductase (higher concentrations in the rough than in the smooth microsomes). DAB-reductase activity may involve 2 components, one which is sensitive to DAB toxicity, and one which is unaffected by DAB and involves the NADPH-cytochrome *c* reductase flavoprotein.

316 INHIBITION BY CHLORAMPHENICOL OF AMINOAZO DYE CARCINOGENESIS IN RAT LIVER: STUDIES OF BIOCHEMICAL CHANGES IN RAT LIVER AND PROTEIN BINDING OF CARCINOGEN. (E.) Blunck, J. M. (Path. Dept. Melbourne, Parkville, Australia). *Chem Biol Interact* 2(3):217-228, 1970.

The protein-bound dye content of the livers of rats fed carcinogens and chloramphenicol, a compound known to inhibit hepatocarcinogenesis in rats, was determined. Rats were given diets containing either 3'-methyl-4-dimethylaminoazobenzene (3'MeDAB) in 0.06% concentration with and without 2% chloramphenicol. No significant differences could be detected between protein-bound dye in livers of chloramphenicol-treated rats and livers of untreated rats. Rats given both 3'MeDAB and chloramphenicol showed greater increases in liver size than rats in other groups. In rats given a diet containing chloramphenicol, liver DNA content after 20 days of the diet was 36.13 mg/100 g body wt, and control liver RNA was 28.30 mg/100 g. Total liver protein also increased in rats given chloramphenicol, and liver DNA was increased in rats given 3'MeDAB-containing diets. In rats given chloramphenicol, the RNA to DNA ratio increased, while in rats given 3'MeDAB alone this ratio decreased; in controls and in rats given both compounds, the ratio remained normal. This observed disturbance of the normal RNA-DNA ratio may be causally connected with 3'MeDAB hepatocarcinogenesis in the rat.

317 ABNORMAL SIZE PROFILES OF SOLUBLE MACROMOLECULES FROM AZO-DYE LIVER TUMORS. (E.) Korof, S. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.), E. M. Young, R. Z. McBride and C. B. Coffey. *Nat Cancer Inst* 46(2):275-280, 1971.

Male rats were fed for 17-27 wk on a diet containing 0.058% 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB); at the end of the feeding period the rats were killed, and the primary liver tumors induced by the carcinogen were prepared for sieving through long gel columns to determine the relative sizes of the soluble macromolecules they contained. Soluble macromolecules were also examined in livers of control rats and in preneoplastic liver tissue from rats given 3'-Me-DAB. Primary liver tumors as well as other tissues yielded soluble macromolecules in size, ranging from 2S to 15-20S; in both control and normal tissues, macromolecule size profiles appeared to break down into discrete and clearly distinguished categories, but the sizes of tumor macromolecules were distributed in diffuse profiles. The 15-20S component was present in greatest abundance (34%) in tumor extracts, but constituted only 10% of the macromolecules for normal liver tissue. The relative amount of 6-7.5S macromolecule in tumor extracts was half that in normal liver tissue. The relative

proportions of many cellular proteins appeared to change following transformation of liver cells to tumors.

1318 PHOSPHOFRUCTOKINASE ACTIVITY AND RATE OF GLYCOLYSIS IN RAT LIVER DURING CARCINOGENESIS. (Rus.) Rubenchuk, B. L. (Inst. Nutr. Hygiene, Kiev, U.S.S.R.) and A. S. Petrun. *Bull Eksp Biol Med* 71(1):68-70, 1971.

Phosphofructokinase activity and the rate of glycolysis in rat liver during *p*-dimethylaminoazobenzene (DAB) carcinogenesis were investigated. A maximum of glycolytic activity (70 mg lactic acid/g protein as compared to 20 mg lactic acid/g protein in controls at 37°C) and a maximum of phosphofructokinase activity (20 μ M NADH/min/g at 25°C, 8 μ M NADH/min/g in controls) were noticed 18 wk after the beginning of the experiment before the occurrence of tumors. When assayed at the time of its maximal activity, phosphofructokinase revealed highest activity using 0.2 mM ATP levels in the presence of 5 mM of $MgCl_2$ and 20 mM of KCl. Its susceptibility towards ATP inhibition decreased in tissue of animals treated with DAB: no phosphofructokinase inhibition occurred with 6 mM of ATP which caused 72% inhibition in control tissue; citrate (5 mM) with ATP (4 mM) inhibited the enzyme by 85% in control tissue and by 36% in the experimental tissue. Enhanced formation of fructose-1,6-diphosphate (200%) coincided with the decrease of the susceptibility of phosphofructokinase towards ATP inhibition. DAB or its metabolites seem to interfere with the allosteric regulators of phosphofructokinase.

1319 ANILINE-INDUCED CHANGES IN THE CORPORA LUTEA OF RATS. (E.) Hatakeyama, S. (Inst. Med. Exp. Surg., U. Montreal, Quebec, Canada), K. Kovacs, E. Yeghiayan and J. A. Blascheck. *Amer J Obstet Gynec* 109(3):469-476, 1971.

Rats were given s.c. injections of 50 mg aniline for 7 consecutive days, killed, and their corpora lutea sectioned for electron microscopy. Aniline-treated corpus luteum cells showed marked intracellular lipid storage with swollen cells displaying either a clear or a foamy cytoplasm. A slight inflammatory reaction was occasionally seen, which consisted of polymorphonuclear leukocytes and mononuclear cells. Multiple theca cell nests, consisting of cells undergoing atrophy, were seen throughout the ovarian stroma. Most lipid-bearing cells in the aniline-treated cells showed no activity of steroid-3 β -ol-dehydrogenase. Succinic dehydrogenase activity was similar in treated and in untreated rats. The fine structure of the mitochondria remained intact in aniline treated rats, but the endoplasmic reticulum decreased markedly and in some cases was entirely absent, suggesting depleted steroidogenesis. Aniline apparently interfered with steroid synthesis in the corpus luteum.

1320 THE BINDING OF ORTHO-AMINOAZOTOLUENE IN PROLIFERATING TISSUES. (E.) Lawson, T. A. (U. Queensland Sch. Med., Herston, Australia)

and F. K. Dzhiyev. *Chem Biol Interact* 2(3):165-174, 1970.

The extent of binding of *ortho*-aminoazotoluene (*o*-AAT) to mouse liver DNA, RNA and protein at various times after partial hepatectomy was investigated; binding of *o*-AAT to mouse-bladder DNA was also investigated in untreated mice and in mice whose bladders contained an implanted glass bead. The level of DNA synthesis in the regenerating liver of partially hepatectomized mice was measured by incorporation of 6-³H-thymidine. By 42-48 hr after hepatectomy, the activity of newly synthesized DNA was 3000 dpm/μg deoxyribose; at 60-66 hr, DNA activity was at 3600 dpm after an intervening drop. The administration of 12 μg *o*-AAT did not affect DNA synthesis in the regenerating liver. A period of increased mitosis was seen in the regenerating liver cells corresponding to the 48 hr maximum recorded for DNA synthesis; at 56 hr the mitotic index was 5; the administration of *o*-AAT did not affect the levels of mitosis in the regenerating cells. The 66 hr maximum for DNA synthesis was followed by a period of poorly synchronized mitosis. The binding of tritiated *o*-AAT to liver nucleic acids and protein in hepatectomized mice resembled the pattern of its binding to liver nucleic acids of intact mice during periods of maximal DNA synthesis and during the period of poorly synchronized mitosis. Binding of *o*-AAT to DNA was increased 6-fold over its normal level during the 56 hr maximum period of mitosis. DNA synthesis in livers of mice undergoing bile duct ligation increased 2-fold over a period of 24 hr; however, bile duct ligation did not affect binding of *o*-AAT to DNA. A 2-fold increase in bladder DNA synthesis also occurred in mice bearing a luminary glass bead in their bladders, but *o*-AAT binding to DNA was unaffected by implantation of the foreign body.

1321 THE LOCALIZATION OF PHORBOL ESTER ¹⁴C-ACETATE IN PAPILLOMAS THAT WERE INITIATED WITH 7,12 DMBA AND PROMOTED WITH PHORBOL ESTER: AN ELECTRON MICROSCOPIC AUTORADIOGRAPHY STUDY. (E.) Bogart, B. (New York U. Med. Ctr., New York, N. Y.), L. Prutkin and P. R. Ocken. *J Invest Derm* 56(2):140-146, 1971.

The tumor enhancing activity of phorbol ester at the cellular level has been studied in female H-ICR mice with ¹⁴C-acetate. In mice pretreated with 7,12-dimethylbenz(a)anthracene (DMBA), the 1st papillomatous growth in response to phorbol ester acetate treatment occurred within 43 days with a yield of 2-5 tumors per animal and ranging in size from 0.25 to 0.5 cm in height. Phase microscopy revealed epithelial hyperplasia of the strata spinosum and granulosum with enlargement of the intercellular spaces in the strata basale and spinosum; extensive numbers of free ribosomes and polysomes were present within the cytoplasm of the cells of these two layers. Tonofibrils, sparse rough endoplasmic reticulum, Golgi apparatus, and chromatin material diffusely scattered throughout the nuclei, which contained 1-3 enlarged nucleoli, were also

noted. Control animals receiving either DMBA or phorbol ester acetate solely developed no papillomatous growths. Phorbol ester acetate appears to gain entrance into the cell as a metabolite which retains the ¹⁴C label.

1322 RADIOAUTOGRAPHIC ANALYSIS OF 7,12-DIMETHYLBENZ(a)ANTHRACENE-³H INCORPORATION AND CELL SURVIVAL OF SYRIAN HAMSTER EMBRYO CELLS DURING EXPOSURE TO NUCLEIC ACID INHIBITORS. (E.) Connell, D. I. (Chester Beatty Res. Inst., London England), L. A. Riechers and J. A. DiPaolo. *J Natl Cancer* 46(1):183-193, 1971.

Alteration by nucleic acid inhibitors of 7,12-dimethylbenz(a)anthracene (DMBA) binding *in vitro* to Syrian hamster 14-day embryo cells, and the effect of inhibitors on DNA and RNA synthesis were demonstrated through radioautographic techniques. Toxicity within the first 12 hr of continuous exposure of culture to DMBA did not indicate a dose response but after 72 hr of treatment with 0.01, 0.04, 0.06, or 0.10 μg DMBA/10⁵ cells, cell survival was 82, 52, 29 and 14%, resp., relative to controls. Seven hr of treatment with 0.01 μg DMBA resulted in survival of 75% of the cells, and cell survivals approximated 80% with 0.04 μg. With concentrations of 0.04 μg DMBA/10⁵ cells, both the percentage of labeled cells and the amount of label incorporated per nucleus increased with length of exposure; the rate of incorporation inversely related to the doubling time of individual cultures, and incorporation of either uridine-³H or thymidine-³H was similar for treated and untreated cells. Hydroxyurea induced a transitory inhibition of thymidine-³H incorporation which was dose-dependent and which was greatest during exposure to 152 μg hydroxyurea/10⁵ cells; the percentage of treated cells that incorporated label after 30 min to 76 μg exposure was 21, while that of controls was 36; however, after 12 hr exposure to the inhibitor, the percentage of cells that incorporated thymidine-³H exceeded control number. Actinomycin D inhibited 60% of the cells binding DMBA-³H with approximately a 60% loss of label, although the level of RNA synthesis returned to normal after 12 hr of incubation; DNA synthesis fell off to less than 40% of control. Actinomycin D and 2-mercapto-1-(β-4-pyridethyl)benzimidazole inhibited DMBA-³H incorporation into the nucleus while hydroxyurea and excess thymidine had no effect. A significant depression in the multiplication of treated cells and a loss of cells followed exposure to any of the inhibitors.

1323 EXPERIMENTAL CANCER OF THE UTERINE CERVIX OF MICE AND RATS: A HISTOLOGICAL AND HISTOCHEMICAL STUDY. (E.) Stenbäck, F. (Dept. Pathol. U. Oulu, Finland). *Ann Med Exp Biol Fenn* 48(4):201-211, 1970.

The development and preliminary stages of carcinogenesis induced histochemical changes in the uterine cervix of 30 NMRI mice and 30 Sprague Dawley rats were studied using 1% 7,12-dimethylbenz(a)anthracene (DMBA) in acetone. In dysplastic epithelium increased amounts of Gram-staining material, disulfide groups, RNA and acid mucopolysaccharides, marked inflammation

reaction and increased numbers of mast cells in sub-epithelial tissues and decreased glycogen content were noted. One carcinoma *in situ* was distinguished by well-differentiated tumor cells tending toward keratinization, high alkaline and acid phosphatase and adenosine triphosphatase activities, regular distribution of oxidative enzymes, connective tissue proliferation and inflammatory reaction in the stroma. A second type was composed of anaplastic cells showing increased lactate dehydrogenase activity, weak phosphatase activity and irregularly distributed oxidative enzyme activity and degeneration of stromal collagen and elastic fibers. With rats, some sarcomas developed originally in cervical connective tissue characterized by fusiform cells of varying degrees of pleomorphism. Correlation of histological progression of neoplastic transformation with histochemical properties of tissue was not adequate for identification of definitely malignant states.

- 1324 DELAYED HYPERSENSITIVITY INDUCED IN GUINEA PIGS BY 7,12-DIMETHYLBENZ(a)ANTHRACENE. (E.) Burger, D. R. (VA Hosp., Portland, Ore.), L. E. Irish, R. M. Vetto and D. J. Hinrichs. *Infect Immun* 3(3):478-480, 1971.

Contact sensitivity elicited in the epidermis of guinea pigs by topical applications of 7,12-dimethylbenz(a)anthracene (DMBA) was investigated. Guinea pigs were presensitized to the carcinogen by applications of a 2% solution of DMBA daily for 7 days; 5 days after sensitization, the animals were skin tested for sensitivity by applications of 1%, 0.5%, and 0.1% DMBA solutions or 1% solutions of benzpyrene, benzan-thracene, or methylcholanthrene. In all guinea pigs reactions typified by homogeneous erythema and induration were observed at the skin test sites 24 and 48 hr after testing with 1% DMBA. Similar reactions were observed after skin testing with benzan-thracene and benzpyrene, but not after methylcholanthrene skin testing. Mononuclear cell infiltration at the skin test site was observed 24 and 48 hr after skin testing, and suprascapular lymph nodes draining the treatment site showed increased numbers of immunoblasts. The sensitivity was transferable by injection of other guinea pigs with peritoneal exudative cells, lymph node cells, and serum from sensitive animals. Contact sensitivity to DMBA was retained for at least 1 yr, during which time none of the sensitized animals developed tumors.

- 1325 EFFECT OF HETEROLOGOUS ANTITHYMOCYTE SERUM ON MOUSE SKIN TUMORIGENESIS. (E.) Haran-Ghera, N. (Weizmann Inst. Sc., Rehovoth, Israel) and M. Lurie. *J Nat Cancer Inst* 46(1):103-112, 1971.

The effect of transient immune impairment on the initiation and promotion phases of skin tumorigenesis was studied by the 2-stage induction method utilizing heterologous antithymocyte serum (ATS) in SWR inbred female mice. Three days after the second of 2 s.c. injections of ATS, tumorigenesis was initiated with a single application of a 1.5% soln of 7,12-dimethylbenz(a)anthracene (DMBA) followed 1 wk later by bi-weekly applications of 5% croton oil for 30 wk; 2 control groups, one with normal rabbit serum in place

of ATS and one without any serum treatment, were used. The first papillomas occurred 5-6 wk later, and by the 10th wk 70-85% of the mice developed an average of 2.5-3.7 papillomas each. Concurrent treatment with ATS during promotion resulted in the appearance of 14-16 papillomas/mouse at 30 wk with no regression at the end of 15 wk following termination of croton oil promotion in contrast to regression in both control groups at this time. Malignant tumors occurred in 33% of the ATS and croton oil-treated mice with an average latent period of 161-201 days. When ATS was injected late in the promotion phase, progression from benign tumors to malignant squamous carcinomas was enhanced with the incidence in the ATS-treated group being 41% compared to 14% in the controls. On the basis of present results, it is doubtful whether the reported suppressive effect of poly I·poly C on DMBA tumorigenesis is mediated through its effect on host immunity.

- 1326 MALIGNANT TRANSFORMATION INDUCED BY 7,12-DIMETHYLBENZ(a)ANTHRACENE IN RAT EMBRYO CELLS INFECTED WITH RAUSCHER LEUKEMIA VIRUS. (E.) Rhim, J. S. (Microbiol. Assoc., Bethesda, Md.), W. Vass, H. Y. Cho and R. J. Huebner. *Int J Cancer* 7(1):65-74, 1971.

Rat embryo cells were infected with Rauscher leukemia virus and treated for 7 days with 7,12-dimethylbenz(a)-anthracene (DMBA 0.01-0.5 µg/ml) to investigate the changes produced in the infected cells by treatment with the carcinogen. In the DMBA-treated and virus-infected cells, morphological alterations of cells and an abnormal pattern of growth were noted 42-45 days after DMBA treatment; similar changes were not seen in uninfected cells treated with DMBA. Uninfected cells treated with DMBA and virus-infected cells not treated with DMBA failed to show any evidence of transformation. Infected DMBA-treated cells showed foci of transformed cells consisting of randomly arranged, criss-crossing spindle-shaped cells. Large cells with atypical nuclei were also observed. The DMBA-treated infected cells had a growth rate 3 times that of virus-infected untreated cells; DMBA treatment inhibited the growth of cells not infected by virus. S.C. sarcomas developed when virus-transformed cells were injected into newborn rats; however, no tumors resulted from injection of infected cells or DMBA-treated untransformed cells. Tumor cells in culture produced group-specific complement fixing antigens characteristic of the murine leukemia-sarcoma viruses and the C-type RNA virus particles. Both DMBA and virus appeared to be necessary for transformation of the rat embryo cells; the viral genome may have provided information for malignant transformation by DMBA.

- 1327 BIOCHEMICAL EVENTS ASSOCIATED WITH REGRESSION OF 7,12-DIMETHYLBENZ(a)ANTHRACENE-INDUCED MAMMARY CARCINOMAS AFTER OVARECTOMY. (E.) Hilf, R. (U. Rochester Sch. Med. Dent., N. Y.), H. Goldenberg, I. Michel, M. Gruenstein, D. R. Meranze and M. B. Shimkin. *Cancer Res* 31(1):52-58, 1971.

The biochemical changes occurring in mammary carcinomas induced in female rats by 7,12-dimethylbenz(a)-

anthracene (DMBA) during tumor regression following ovariectomy were investigated. Rats were given 5 mg DMBA by stomach instillation; at various times after the appearance of mammary tumors, rats were ovariectomized and sacrificed 1, 5 or 14 days later. No significant decrease in tumor size or volume occurred until 14 days after ovariectomy, at which time tumor size and volume had decreased 27% and 62%, resp. Tumors obtained 1 day after ovariectomy showed a 48% decrease in normal glucose-6-phosphate dehydrogenase activity, and a 34% decrease in cholesterol activity. Aspartate aminotransferase increased 72% in ovariectomized rats on day 1, and hexokinase had increased by 340%. By day 5 after ovariectomy there was a 32% decrease in the RNA to DNA ratio in the DMBA-induced tumors, a 49% decrease in phosphoglucumutase, a 61% decrease in glutamate dehydrogenase and a 33% decrease in pyruvate kinase activity. By 14 days after ovariectomy, NADP-malate dehydrogenase activity was reduced by 45%, and the RNA level was reduced 40%, and none of the altered parameters observed on earlier days had returned to normal levels. NADP-isocitrate dehydrogenase and glucose-phosphate isomerase were also altered on day 14, but DNA and free fatty acid were not affected by ovariectomy. Rats ovariectomized when their first DMBA-induced tumor had reached 2 x 2 cm and rats ovariectomized 35 days after their first tumor had reached 0.5 x 0.5 cm exhibited similar biochemical alterations.

- 1328 EFFECT OF PINEALECTOMY UPON MELANOID TUMORS IN THE GOLDEN HAMSTER INDUCED BY ORAL ADMINISTRATION OF A SINGLE DOSE OF 9,10-DIMETHYL-1,2-BENZANTHRACENE. (Fr.) Aubert, C. (Inst. Gustave-Roussy, Villejuif, France), M. Prade and C. Bohuon. *C R Acad Sci* 271(25):2465-2468, 1970.

The role of the pineal body was investigated in golden hamsters with melanoid tumors induced by the administration of 7,12-dimethylbenz(a)anthracene (DMBA). In the 2 groups of animals, intact and pinealectomized, the melanoid tumors appeared 4 months after the ingestion of DMBA. These were of variable size in the same animal, ranging from microscopic to 2-3 cm in diameter. Pinealectomy resulted in a considerable increase in the number of melanoid tumors, but did not alter the size or the histological character of the tumors; females had fewer tumors than males. The absence of the pineal body increased the tumorigenic effect of DMBA in the formation of melanoid tumors in the golden hamster, but this enhancement appears to be reduced by the female hormones. Whether the mechanism of action is entirely hormonal in nature or an immunologic response is still to be determined.

- 1329 RADIOLOGICAL AND MORPHOLOGICAL FEATURES OF CHEMICALLY-INDUCED OSTEOSARCOMAS IN CONDITIONS OF HYPERESTRINISM. (Rus.) Kornitsky, M. A. (Med. Inst. Orenburg, U.S.S.R.) *Vop Onkol* 16(12):44-49, 1970.

The morphological changes associated with the development of 7,2-dimethylbenz(a)anthracene (DMBA)-induced osteosarcoma in rabbits in conditions of

hyperestrinism was followed by roentgenology. Seventy female rabbits (5-7 months old) were implanted with a paraffin tablet containing 10 mg of DMBA in the proximal metaphysis of the tibia; 3 experimental groups were established: I) 20 rabbits received additional treatment; II) 40 rabbits were treated with a 2% oil solution of synestrol (0.2-0.3 ml twice a wk) starting 14 days after the implantation of the carcinogen; III) 10 rabbits were subjected to the same synestrol treatment starting 4 days after the implantation of the carcinogen. Roentgenologically detectable osteosarcoma developed in 10 of 20 rabbits of the Group I 193-210 days following carcinogen treatment. Eight rabbits of the group II developed 3 presarcomatous neoplasms: 3 small intramedullary sarcomas and 2 large osteosarcomas 220-430 days after carcinogen treatment. The rabbits of group III exhibited presarcomatous conditions in 3 cases 90-99 days after carcinogen implantation and actual sarcomas in 2 cases. The development of presarcomatous and sarcomatous regions occurred in conditions of diffuse bone demineralization caused by synestrol treatment. The presarcomatous alterations exhibited no specific roentgenological patterns in all the experimental animals. Development of osteosarcoma appeared roentgenologically as a fast growing enlargement of the surgical scar associated with the appearance of sclerotic foci around the scar, the destruction of the cortical layer and the neoplastic invasion outside the bone tissue in the rabbits of the Group I. The development of osteosarcoma in conditions of hyperestrinism presented specific roentgenological features such as repair processes within the metaphysis and sclerotic foci occurring much later than in the non-hormone-treated group. The developed tumors were morphologically classified as osteoid sarcoma, chondrosarcoma or polymorphic cell sarcoma. The morphology of osteoid fibrosarcomas revealed no destruction of the bone structures. Synestrol treatment decreased the incidence of induced osteosarcoma.

- 1330 SKIN TUMORIGENESIS IN MICE BY PETROLEUM ASPHALTS AND COAL-TAR PITCHES OF KNOWN POLYNUCLEAR AROMATIC HYDROCARBON CONTENT. (E.) Wallcave, L. (U. Nebraska Coll. Med., Omaha), H. Garcia, R. Feldman, W. Lijinsky and P. Shubik. *Toxic Appl Pharmacol* 18(1):41-52, 1971.

The tumorigenic effect of polynuclear hydrocarbon contained in petroleum asphalts and coal-tar pitch was investigated in mice given topical application of coal-tars and asphalts. Polynuclear aromatic hydrocarbons contained in the 2 media included coronene, picene, benzo(e)pyrene, chrysene, benz(a)anthracene and phenanthracene. Asphalt (2.5 mg) or coal-tar pitch (1.7 mg) was applied to a 1 square inch zone of the dorsal skin of adult mice twice a wk for periods up to 82 wk. Both coal tar and asphalt induced epidermal hyperplasia. Animals given asphalt frequently developed amyloidosis, particularly in the spleen and kidney. Coal-tar painted animals developed squamous cell carcinomas, benign squamous cell papillomas and keratoacanthomas. Carcinomas were developed by 31 coal-tar treated mice and by 2 asphalt-treated mice. In all, 91% of the

animals developed some form of skin tumor. Subcutaneous and internal tumors were observed in all treatment groups, including lung adenomas, malignant lymphomas, and endometrial carcinoma.

331 CHARACTERISTICS OF PRIMARY TUMORS INDUCED BY CARCINOGENIC POLYCYCLIC HYDROCARBONS IN SYRIAN HAMSTERS. (E.) DiPaolo, J. A. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), R. L. Elson and P. J. Donovan. *J Nat Cancer Inst* 46(1): 71-181, 1971.

Induction of primary tumors with a single s.c. injection of benzo(a)pyrene (0.1 µg) or 7,12-dimethylbenz(a)anthracene (0.1 mg) in Syrian hamsters and the characteristics of the cultures resulting from them are reported. Tumors were found only in the s.c. region of the groin at the site of inoculation and consisted of a single, firm encapsulated mass, easily removed from surrounding connective tissue and microscopically identifiable as fibrosarcomas; structurally different types were recognizable. The fibroid type with interlacing bundles oriented in many planes was very common; undifferentiated tumors showed considerable anaplasia and multilobulation with loose attachment to the skin and fascia, while mucoid mesenchymal tumors were characterized by active division and indistinct cellular boundaries. Primary tumors had common structural characteristics, whether induced with benzo(a)pyrene or 7,12-dimethylbenz(a)anthracene and secondary tumors resembled the parent tumor mass. Tumor cultures showed an increase in acid production, piling up of cells, general lack of cell orientation, and transformed colonies with tumorigenic potential were demonstrated with all culture lines. Chromosomal examination revealed 2 tumor lines with near-diploid modes, 1 with a diploid mode and 3 lines with hypotetraploid modes with chromosome numbers varying from 39 to 90, and acentric fragments and extra chromosomes appeared in 25-80% of the cells. This study of tumor cell cultures from *in vivo* carcinogen-induced tumors indicates that *in vitro* chemical transformation is a relevant model system for carcinogenesis since the characteristics of the tumor cell lines in culture paralleled for the most part the observations seen with *in vitro* transformation by this same class of carcinogens.

332 CARCINOGENIC EFFECTS OF POLYCYCLIC HYDROCARBON CARCINOGEN ADMINISTRATION TO MICE DURING PREGNANCY ON THE PROGENY. (E) Gulay, O. M. (Dept. Path., Ankara U., Turkey) and W. Wattenberg. *J Nat Cancer Inst* 46(2):397-402, 1971.

On days 11, 13 and 15 of pregnancy, female ICR/Ha mice were given i.p. injections of benzo(a)pyrene (BP, 4 mg) or 7,12-dimethylbenz(a)anthracene (DMBA, 2 or 4 mg). The progeny at birth were either nursed by foster mothers or by their own mothers, and tumor development was observed. Maternal exposure to BP was found to result in an increase in pulmonary adenomas among offspring nursing on their own mothers; progeny of mothers given BP showed a tumor incidence 35% greater than that of progeny of mothers not given BP. Progeny of mothers given

BP and delivered by caesarian section which were nursed by foster mothers also had a higher incidence of pulmonary adenomas than progeny of caesarian-delivered, non-nursing mothers not given BP; the former group developed 65% more tumors than the latter. DMBA was found to be a more potent inducer of pulmonary adenomas among offspring of treated mothers than BP. Progeny of BP-treated mothers delivered by caesarian section and nursed by foster mothers developed fewer tumors (39.5%) than progeny of DMBA-treated, caesarian-delivered, non-nursing mothers (48.0-97.7%), the percentage increasing with increasing dosage of DMBA. Both BP and DMBA, when given to mothers, increased the incidence of skin papillomas induced by topical application of croton oil in the progeny. DMBA given to mothers induced ovarian tumors in the female progeny of treated mice; however, BP had no such effect.

1333 3,4-BENZOPYRENE CONTENT IN HUMAN ORGANS OF VARIOUS AGE GROUPS. (Ger.) Graf, W. (Inst. Hyg., U. Erlangen-Nürnberg, Germany). *Arch Hyg Bakt* 154(4):331-335, 1970.

The benzo(a)pyrene (BP) content in various organs of man was analyzed and the findings were classified according to age; liver, spleen, kidneys, cardiac and skeletal muscle BP contents were divided into 6 groups according to age: 0 to 1 yr; 1 to 5; 5 to 15; 15 to 25; 25 to 50; and over 50 yr. The results revealed 2 maximal BP concentrations in each of the organs investigated; these maxima occurred in infancy and again in the age group over 50 yr. A V-shaped curve emerged when the mean values of the total BP contents were plotted according to age, again showing peaks at infancy and old age, with a minimum in the age bracket between 5 and 15 yr. In all age groups the highest mean values of BP were found in skeletal musculature and in the kidneys, and the mean value in BP content of all the organs investigated was 0.32 µg/100 gm dry wt. The presence of the carcinogen in the infant may be ascribable to endogenous sources, but the concentration in the higher age groups is consistent with exogenous and cumulative action.

1334 STIMULATORY EFFECT OF BENZO(a)PYRENE AND PHENOBARBITAL PRETREATMENT ON THE BILIARY EXCRETION OF BENZO(a)PYRENE METABOLITES IN THE RAT. (E.) Schlede, E. (Pharmacol. Inst. Free U. Berlin, Germany), R. Kuntzman and A. H. Conney. *Cancer Res* 30(12):8298-2904, 1970.

Female rats were treated daily with 20 mg/kg of benzo(a)pyrene (BP) p.o. or with i.p. injections of 37 mg/kg of phenobarbital; treatment periods for BP and phenobarbital were 2 and 4 days, resp. Twenty-four hr after pretreatment, rats were given i.v. injections of 10 or 300 µg ¹⁴C-BP. The concentration of radioactive BP metabolites in the bile 7 min after injection of 300 µg of labeled BP was 20-fold higher than in the controls given no pretreatment; after injection of 10 µg of labeled BP, the concentrations of metabolites was 6-fold higher in pretreated than in control rats. By 300-420 min after injection, BP metabolites in the bile of pretreated and control

rats given 10 µg labeled BP had declined to 9 and 12 dpm/µl bile, resp.; initial values for BP metabolites in the bile of pretreated and control rats were, resp., 300 and 50 dpm. Pretreatment with phenobarbital also enhanced ¹⁴C-BP metabolite concentrations in bile. Pretreatment of rats with ¹⁴C-labeled metabolites of BP had no effect on concentrations of BP metabolites in bile, which appeared to indicate that pretreatment with BP or phenobarbital did not enhance the transport of BP metabolites into bile, but enhanced the formation of BP metabolites. Evidently, the hydroxylation of ¹⁴C-BP in living rats is potentiated by pretreatment with BP, while phenobarbital does not produce this effect. Pretreatment with phenobarbital may enhance the biliary excretion of labeled BP metabolites by enhancing the conjugation of hydroxylated BP metabolites.

- 1335 EFFECT OF ENZYME INDUCTION ON THE METABOLISM AND TISSUE DISTRIBUTION OF BENZO(a)PYRENE. (E.) Schlede, E. (Pharmacol. Inst. Free U. Berlin, Germany), R. Kuntzman, S. Haber and A. H. Conney. *Cancer Res* 30(12):2893-2897, 1970.

The effect of pretreatment with benzo(a)pyrene (BP), 3-methylcholanthrene (MC) or 7,12-dimethylbenz(a)anthracene (DMBA) on the metabolism of BP was investigated in rats. Rats were given p.o. doses of 1 of the hydrocarbons once daily for 2 days prior to the i.v. administration of 115-250 µC of ³H-BP, and the disappearance of the labeled compound from blood, liver, brain and fat was examined. BP content in the blood of untreated controls and pretreated rats in the first min following the injection of ³H-BP was 193 and 155 ng/ml, resp. By 5 min postinjection, ³H-BP in the blood of controls was 30 ng/ml of blood, while in the rats pretreated with nonradioactive BP, the level was 5 ng/ml. Levels of ³H-BP in pretreated animals were consistently below those in controls. In the blood of rats pretreated with MC the ³H-BP level was 0.5 ng/ml, while in the blood of controls ³H-BP levels were 2.9, and DMBA pretreatment reduced ³H-BP concentrations to 0.7 ng/ml. Phenobarbital pretreatment reduced ³H-BP levels to 2.3 ng/ml compared to 2.5 ng/ml for controls. As with phenobarbital, pretreatment with anthracene or pyrene did not affect disappearance of ³H-BP. After 7 administrations of tritiated BP the ³H-BP content of rat fat was lower than after a single dose of the labeled compound, indicating that BP stimulates its own metabolism when administered chronically.

- 1336 THE STUDY ON THE MALIGNANT CHANGES OF BRONCHIAL EPITHELIAL CELLS IN MICE INDUCED BY THE INHALATION OF PARA-BENZOQUINONE. (Jap.) Otsu, H. (Sch. Med. Chiba U., Japan). *J Chiba Med Soc* 46(4):461-472, 1970.

Forty-five mice were maintained for more than 300 days on a regimen of para-benzoquinone inhalation (200 mg/day in a 340 l chamber); 4 mice developed lung cancer, 7 developed atypical adenomatous proliferation and 5 developed atypical growths of the terminal bronchial cells. Cancer cells showed stronger color development associated with cathepsin activity than

did terminal bronchial epithelial cells or atypical adenomatous proliferative cells. The color development was strongest in the area corresponding to the clear portion of the cytoplasm in the cancer cells. Under the light microscope, some cancer cells showed clear vacuolar areas of cytoplasm adjacent to the stroma; these areas stained only weakly with eosin, but had intact nuclei. Under the electron microscope, cancer cells and atypical adenomatous proliferative cells showed little electron density in their cytoplasm near the stroma. These cells occasionally were seen to protrude a part of their cytoplasm through the basement membrane into adjoining stroma which then degenerated and became necrotic. These morphological changes were thought to be associated with invasion by malignant cells.

- 1337 EFFECT OF ADMINISTRATION OF 3-METHYLCHOLANTHRENE ON THE SALT-EXTRACTABLE CHROMATIN PROTEINS OF RAT LIVER. (E.) Yee, M. (Baylor Coll. Med., Houston, Tex.) and E. Bresnick. *Molec Pharmacol* 7(2):191-198, 1971.

Treatment with 3-methylcholanthrene (3-MC) (20 mg/kg body wt, i.p.) increased the efficacy of rat liver chromatin as a template for RNA synthesis; when the 3-MC chromatin system was extracted with 2 M NaCl chromatin RNA template activity returned to normal levels. The salt-extractable protein components of 3-MC-treated rat liver chromatin were investigated observing the incorporation of ¹⁴C-labeled lysine into NaCl extractable proteins. Twenty min after the administration of ¹⁴C-lysine to rats, the ratio of incorporation of the label in salt-extractable proteins in 3-MC-treated rats to that in controls was 1:3, while 30 min after treatment with the label this ratio was 1:9; 60 min after treatment, the ratio was 2:4. Although the enhanced incorporation of ¹⁴C-lysine into salt-extractable liver chromatin proteins was considerable by 3 hr after 3-MC treatment, maximum enhancement occurred between 6-24 hr after treatment with the carcinogen, at which time the specific activity of the salt-extractable protein fraction from the livers of drug-treated rats was twice the value observed in animals not given 3-MC. Treatment with 3-MC did not affect the incorporation of ¹⁴C-labeled tryptophan into the 2 M NaCl-extractable liver proteins.

- 1338 INTERACTION OF 3-METHYLCHOLANTHRENE WITH LECITHIN-CHOLESTEROL MIXED FILMS. (E.) Weiner, N. D. (Coll. Pharm. Sci., Columbia U., New York, N. Y.), I. Chawdry and A. Felmeister. *J Pharm Sci* 60(3):425-428, 1971.

When a 50:50 molar ratio mixed film of cholesterol and methylcholanthrene (MC) was spread, the film exceeded that formed by cholesterol, indicating that MC interacted with cholesterol. No discernible interaction was seen between MC and lecithin in films containing both as components. In films composed of cholesterol and lecithin in 50:50 ratios, the interaction of the film with MC was weak, suggesting that when the lipid-lipid interaction is maximal, MC-lipid interaction is minimal. The findings

appeared to indicate that the extent of MC-cholesterol interaction is influenced by the competitive interaction of cholesterol and lecithin. Such competitive interactions may explain the fact that lecithin and other phospholipids retard, while cholesterol enhances, the formation of tumors induced by MC and other hydrocarbons.

- 339 EFFECT OF COBALT CHLORIDE AND SODIUM COBALTINITRIDE ON THE GROWTH OF ESTABLISHED EPITHELIAL TUMORS INDUCED BY METHYLCHOLANTHRENE. (E.) O'Hara, G. P. (Sch. Pharm. Temple U., Philadelphia, Pa.), D. E. Mann, Jr. and R. F. Gautieri. *Pharm Sci* 60(3):473-474, 1971.

The effect of cobalt chloride and sodium cobaltinitrite treatment on the growth of established skin tumors in mice was investigated. Mice of both sexes were given minimal carcinogenic doses of methylcholanthrene (21 biweekly applications of minimal carcinogenic doses of methylcholanthrene in acetone). After the cessation of methylcholanthrene treatment, mice in 1 group were given 25 mg/kg cobaltous chloride, and mice in 2 other groups were given 50 or 60 mg/kg sodium cobaltinitrite (i.p. biweekly for 1 wk). It was found that the group of mice given 0 mg cobalt nitrite had twice as many tumor regressions and less than half the number of new tumors than controls receiving no cobalt, but this finding did not represent a significant change. There was no apparent difference between controls and cobalt-treated mice on tumor growth; cobalt treatment does not seem to affect the growth of established, differentiated tumors.

- 340 CHROMOSOMES OF MAMMARY CARCINOMAS INDUCED BY 3-METHYLCHOLANTHRENE IN RATS. (E.) Rajumdar, S. K. (Dept. Biol., Lafayette Coll. Easton, Pa.) and E. D. Rees. *J Heredity* 61(6):231-236, 1970.

Cytotype studies were performed on cells from mammary carcinomas induced in female rats by intrastatic administrations of 3-methylcholanthrene (40 mg/100 g body wt for 5 doses). The modal chromosome number for each of the tumors was the usual rat diploid number of 42. Chromosomes were studied in direct cell preparations, and in cells from short-term cultures. In short-term cell cultures, chromatid breaks, gaps, fragments, stickiness and heteromorphic chromosomes were seen in 20% of the carcinoma cells. Alterations for the most part involved the X, 4-10, number 11-13 and number 14-20 chromosome groups. Cytotypes were generally normal; marker chromosomes were rarely seen. Twenty-seven percent of diploid chromosomes in the short-term cell culture preparations lacked at least one number 11-13 group chromosome, possibly due to the loss of short chromosome arms.

- 341 THE BINDING OF 3-METHYLCHOLANTHRENE TO MACROMOLECULAR COMPONENTS OF RAT LIVER PREPARATIONS. (E.) Hey-Ferguson, A. (Baylor Coll. ed., Houston, Tex.) and E. Bresnick. *Molec Pharmacol* 72(2):183-190, 1971.

Rat liver homogenates were centrifuged for the separation of the 9000 x g supernatant fractions, and the binding of this fraction with 0.25 μ C 14 C-3-methylcholanthrene (3-MC) together with a pyridine nucleotide was studied. This mixture was examined by chromatographing the 100,000 x g supernatant liquid obtained by centrifugation of the incubation medium on Sephadex G-100. The elution pattern consisted of 2 UV-absorbing, radio-actively labeled peaks designated A and B; peak A was eluted in the void volume, and was thought to consist mostly of RNA, while peak B was partially excluded and consisted mostly of proteins. If microsomes or the pyridine nucleotide were deleted from the reaction mixture, peak B failed to appear on chromatography. Peak A appeared even in the absence of the pyridine nucleotide and microsomes. Treatment of rats with 3-MC 24 hr before death enhanced the height of peak B but did not markedly affect the formation of peak A. An elution peak analogous to peak A was found when the same procedures were carried out using rat heart and kidney homogenates; spleen homogenates did not give a peak A. Peak B was not formed in heart and spleen and was very low in kidney. The results seemed to confirm that 3-MC or a derivative of it binds to the macromolecular components of the 9000 x g supernatant fraction of rat liver homogenate; the function of the bound 3-MC remains speculative.

- 1342 THE MORPHOLOGICAL AND HISTOENZYMATIC PROPERTIES OF EXPERIMENTAL BRAIN SARCOMAS CULTURED *IN VITRO*. (E.) Renkawek, K. (Polish Acad. Sci., Warsaw) and H. Kroh. *Z Krebsforsch* 75(2):123-132, 1971.

The morphological and histoenzymatic properties of 15 experimental brain fibrosarcomas and giant cell sarcomas induced in C₃H strain mice by methylcholanthrene implantation were investigated in tissue culture. The fibrosarcoma from intra- and extra-cerebral tumors showed similar morphological features exhibiting slow growth with the first cells appearing after 1 wk; considerable cellular polymorphism with a relatively monotypic appearance of the nuclei was observed. In cultures of tumors identified in tissue sections as giant cell sarcomas, the tumor cells grew out of the explant on the third day of culture and exhibited expansive growth with highly polymorphic nuclei containing distinct granular chromatin and numerous atypical mitoses. The amount of PAS-positive granules was less in the giant cell sarcoma whereas the fibrosarcoma cells showed high glucose-6-phosphate dehydrogenase activity. These findings agreed with results previously reported by other investigators.

- 1343 THE ACTIVITY OF COLLAGENASES AND COLLAGEN CONTENT IN THE SKIN DURING CARCINOGENESIS. (Ger.) Rohrbach, R. (Path. Ins. U. Freiburg, Germany), C. Thomas, R. Rümpler and M. Lau. *Verhandl Deutsch Ges Path* 54:442-450, 1970.

Collagenolytic activity was investigated in hairless mice during carcinogenesis of the skin induced by methylcholanthrene and dimethylbenzanthrene solutions

in acetone (0.25%). The mice were sacrificed at different times, and the epidermis with the corium and papillomas or carcinomas were examined after suitable preparation. The DNA content/dry wt of corium and epidermis remained unaltered in the acetone-treated controls, and the epidermis of these animals showed a two-fold higher DNA content than the corium. In the experimental animals the DNA content of the epidermis was decidedly increased and that of the corium only slightly increased. The DNA content of the skin papillomas was 50-70% higher than that of the tumor-free surrounding tissue. Collagenase activity in the carcinogen-treated skin was markedly higher in the corium than in the epidermis. The DNA content of the benign skin papillomas and of peripheral carcinoma portions was about the same, but the carcinoma periphery showed a higher collagenase activity. The application of carcinogens for 20 wk produced a 50% increase in DNA content and a 300% increase in collagenolytic activity, which was particularly marked in the corium. Although a decided difference in collagen activity is shown between neoplastic and healthy skin, the changes may not be applicable to internal organs.

- 1344 PROPERTIES OF CYTOCHROME P-450 AS AFFECTED BY ENVIRONMENTAL FACTORS: QUALITATIVE CHANGES DUE TO ADMINISTRATION OF POLYCYCLIC HYDROCARBONS. (E.) Mannering, G. J. (U. Minnesota Coll. Med. Sci., Minneapolis). *Metabolism* 20(2):228-245, 1971.

The effect of polycyclic hydrocarbons on the properties of cytochrome P-450 was studied in rat hepatic microsomes through metabolic and spectrophotometric techniques. N-demethylation of ethylmorphine was inhibited 35-47% in non-pretreated controls, phenobarbital- and 3-methylcholanthrene-treated rats with administration of 2-diethylaminoethyl-2,3-diphenylvalerate hydrochloride; N-demethylation of 3-methyl-4-methylaminoazobenzene was also inhibited. However, in the 3-methylcholanthrene-treated rats 10 times more reagent was needed to exert a 50% inhibition. Spectral peaks observed at 430 and 455 nm were plotted against pH independently to give an intercept at about pH 7.4 for untreated and phenobarbital-treated animals; for 3-methylcholanthrene-treated animals, the intercept was at pH 6.9, indicating the formation of a new hemoprotein P₁-450. The second peak seen with microsomes from animals treated with polycyclic hydrocarbons was located at 453 nm rather than at 455 nm. The pH intercept was shown to bear an inverse relationship to the increased rate of N-demethylation. Aggregated cytochrome P₁-420 showed type II binding only upon desalting in contrast to type I and II binding with drugs seen with cytochrome P-420; absolute spectra of cytochrome P₁-450 differed only slightly from those produced by cytochrome P-450, and incubation of microsomes with polycyclic hydrocarbons did not cause the formation of a P-450 hemoprotein with characteristics of cytochrome P₁-450. That cytochrome P₁-450 may be an aberrant hemoprotein is suggested by its absence in measurable quantity in microsomes from untreated rats and by its apparent lack of a type I binding site.

- 1345 DIETHYLNITROSAMINE CARCINOGENESIS. (E.) Mohr, U. (Med. Coll. Hannover, Germany). *Fortschr Med* 89(6):251-253, 1971.

Experimental pulmonary tumors were obtained in the golden hamster with diethylnitrosamine (DENA) administered by p.o. intubation, intratracheally spray, or s.c. injection. Basal cell hyperplasia and squamous epithelial metaplasias were obtained in the area of the mucosa of the tracheobronchial tree within a few wk, and after 4 months of treatment longer, tracheal papillomas developed as well as squamous epithelial and adenocarcinomas of the lung. The s.c. administration produced tumors in the shortest period of time. The concept of organotropy supported by this type of experiment, since in the p.o. intubation of DENA produced neoplasms in the liver and kidneys. Other experiments in the golden hamster with nitrosamine derivatives, acetoaminofluorene and benzopyrene also led to pulmonary tumors. The carcinogen (DENA) was also tested in pregnant animals by s.c. injections during the second half of their pregnancy. After 25 wk, 74% of the mothers and 42% of the offspring showed the squamous epithelial metaplasias in the respiratory mucosa.

- 1346 DIMETHYLNITROSAMINE FORMATION FROM SODIUM NITRITE AND DIMETHYLAMINE BY BACTERIAL FLORA OF RAT INTESTINE. (E.) Klubes, P. (George Washington U. Sch. Med., Washington, D. C.) and W. R. Jondro. *Res Commun Chem Path Pharmacol* 2(1):24-34, 1971.

The formation of the carcinogenic compound dimethylnitrosamine from dimethylamine and sodium nitrite by bacterial flora in the rat cecal contents was investigated. Rat cecal contents were incubated with ¹⁴C-labeled dimethylamine and sodium nitrite at neutral pH under anaerobic conditions, resulting in synthesis of 70-108 μmoles of nitrosamine in the presence of 20 hr. The omission of glucose from the reaction system diminished the yield of dimethylnitrosamine, suggesting that the formation of the carcinogen is dependent on the metabolic activity of the intestinal microorganisms. Inasmuch as nitrites are common additives, these results suggest that dimethylnitrosamine synthesis from dimethylamine in the presence of nitrites constitutes a risk for humans.

- 1347 CARCINOMA OF THE GALLBLADDER INDUCED IN HAMSTERS BY INSERTION OF CHOLESTEROL CRYSTALS AND FEEDING DIMETHYLNITROSAMINE. (E.) Kowalewski, K. (Surg. Med. Res. Inst., U. Alberta, Edmonton, Canada) and E. F. Todd. *Proc Soc Exp Biol Med* 136(2):482-486, 1971.

The induction of gallbladder neoplastic lesions resulting from chronic, nonspecific irritation of the gallbladder mucosa induced by an "experimental cholesterol gallbladder stone" was studied in dimethylnitrosamine-treated male hamsters. In dimethylnitrosamine-treated animals hepatocellular and cholangiocarcinomas resulted in which proliferating bile ducts were lined with atypical epithelial cells showing abnormalities in nuclear polarity, variation in nu-

size and shape, hyperchromatism and an increase in the number of mitotic figures. Sixty-eight percent of dimethylnitrosamine-treated animals with implanted cholesterol pellets developed carcinoma of the gallbladder and only 1 animal without pellet implantation showed signs of carcinoma of the gallbladder. Gallbladder pellets alone had no carcinogen effect even after 40 wk of implantation. Experimental gallbladder stones appear to enhance the malignant transformation of gallbladder mucosa in dimethylnitrosamine-treated animals, but diethylnitrosamine did not affect the gallbladder.

- 1348 DIFFERENCES IN TUMOR TYPES AND ORGAN SUSCEPTIBILITY IN BALB/c AND RF MICE FOLLOWING DIMETHYLNITROSAMINE AND DIETHYLNITROSAMINE. (E.) Clapp, N. K. (Oak Ridge Natl. Lab., Tenn.), R. L. Tyndall and J. A. Otten. *Cancer Res* 31(2):196-198, 1971.

The oncogenic effects of dimethylnitrosamine (DMN) and diethylnitrosamine (DEN) in adult BALB/c mice were compared to previously reported effects on RF/Un mice; the carcinogens were administered in drinking water for varied periods of time. Liver hemangiosarcomas were induced by both carcinogens in BALB/c mice and by dimethylnitrosamine in RF/Un mice, while diethylnitrosamine induced liver hepatomas in RF mice and forestomach and esophageal squamous cell carcinomas in both strains. In addition, dimethylnitrosamine treatment resulted in lung adenomas in both strains. The data suggest that the strain susceptibility to tumor induction is not necessarily related directly to the carcinogenic results following treatment with a powerful carcinogen; however, a compound-enzyme specificity may exist within certain cells of an organ which enables these cells to metabolize the carcinogen to a proximate carcinogen.

- 1349 CHANGES IN THE CONCENTRATIONS OF NUCLEIC ACIDS AND HISTONE IN EXPERIMENTALLY INDUCED TUMORS: CYTOPHOTOMETRIC STUDIES. (Ger.) Tasca, C. (German Cancer Res. Ctr., Heidelberg), D. Haag and K. Goerttler. *Verhandl Deutsch Ges Path* 54:458-464, 1970.

An account of small but definite deviations from the norm in 10 experimentally produced tracheal papillomas is presented. The tissues were obtained from pregnant golden hamsters which had been injected with 50 mg/kg of diethylnitrosamine and from their offspring. The morphological changes investigated were nuclear volumes, nucleic acid content, and the histone content compared with normal tracheal mucosa. Nuclear volumes of the papilloma cells were twice that of normal mucosa cells, and a corresponding decrease was seen in concentration of DNA, total nucleic acids, and histones in the papillomas compared with normal tissue and the total amount of DNA, total nucleic acids, and histones were only slightly increased over normal cells. Correlations between DNA and total nucleic acid quantities and nuclear cell volume were obtained by means of regression analysis, which showed that there was a disturbance in these ratios

in the papilloma cells. Although there was no sharp change between the normal and diseased cells by this method, there appeared to be a continuous transformation which was detected by mathematical calculations. (13 references)

- 1350 SPECIFIC PHASES OF GROWTH-BEHAVIOR OF PRENEOPLASTIC CELLS DURING CARCINOGENESIS. (Ger.) Rabes, H. (Path. Inst. U. Munich, Germany), P. Scholze and R. Hartenstein. *Verhandl Deutsch Ges Path* 54:428-433, 1970.

The rate of cell proliferation during diethylnitrosamine (DENA) carcinogenesis was followed in the livers of partially hepatectomized and intact rats by monitoring ^3H -thymidine incorporation. From the start of DENA feeding (5 mg/kg daily) up until 130 days, 2 rats were injected with the ^3H -thymidine every 10 days, and 3 rats were partially hepatectomized every 10 days and injected with ^3H -thymidine 20 to 56 hr after hepatectomy. The liver was removed 4 hr after the last injection, and histochemical studies were made on cryostat serial sections. Changes in the growth fraction were observed 10 days after DENA feeding in the partially hepatectomized animals, and enzymatic activity and DNA synthesis were inhibited. The enzyme depleted liver cells showed only a slight proliferation on the 90th day, but proliferation was abundant in partially hepatectomized animals. At about the 120-130th days there was a marked increase in proliferation. A latent period of variable intervals occurred in tumor formation, which was dependent upon the homeostatic regulation of the specific organ.

- 1351 DIBUTYLNITROSAMINE CARCINOGENESIS IN SYRIAN GOLDEN AND CHINESE HAMSTERS. (E.) Althoff, J. (U. Nebraska Coll. Med., Omaha), F. W. Krüger, U. Mohr and D. Schmahl. *Proc Soc Exp Biol Med* 136(1):168-173, 1971.

The carcinogenic effects of dibutylnitrosamine (DBN) were investigated in male Syrian golden hamsters and Chinese hamsters. Hamsters were given intragastric or s.c. injections of 300 mg/kg body wt of DBN once a wk for life. Intragastric and s.c. injection produced similar mortality and carcinogenic effects. By 23 wk after the treatment was begun papillomas were found in the urinary bladders of hamsters; squamous cell carcinoma areas were also seen. In the nasal and paranasal cavities of both Syrian and Chinese hamsters, papillomas were observed after 30 wk and squamous cell carcinomas after 35 wk. Tumor incidences approached 5-10%. Tracheal papillomas developed in Syrian hamsters by wk 23, and lung tumors developed after wk 25. In Syrian hamsters, lesions of the upper digestive tract were rare; however, in Chinese hamsters, 25% of the animals developed papillomas or squamous cell carcinomas on the hard palate or elsewhere in the oral cavity. Multiple papillomas in the forestomach were also common.

- 1352 MORPHOGENESIS AND FINE STRUCTURE OF EXPERIMENTAL RENAL CLEAR CELL TUMORS. (Ger.) Bannasch, P. (Path. Inst. U. Würzburg, Germany) and

U. Schacht. *Verhandl Deutsch Ges Path* 54:464-471, 1970.

Clear cell adenomas and carcinomas induced by N-nitrosomorpholine administered to rats in their drinking water in the concentration of 12mg% are described. Out of the 97 experimental animals with various types of epithelial renal tumors, 18 developed predominantly or partially clear cell tumors 4-19 months following the administration of the carcinogen. Morphologically these tumors resembled those described in humans by Grawitz and were so small that most could only be perceived microscopically, but some could grow to a diameter of about 2 cm. The light microscopic and electron microscopic studies showed the characteristic glycogen masses in layers of cytoplasm, and, more rarely, lipid deposits, a few mitochondria, and single ergastoplasm profiles and free ribosomes. Some of the tumor cells contained an abundance of mitochondria with many morphological changes. It was also possible to follow the cell transformation in the renal tubules, the formation into cyst-like shapes and further development into transparent epithelium. The glycogen storage cells in the first stages of tumor formation were transformed into glycogen-free tumor cells and eventually resulted in a glycogen-free tumor.

1353 ESTABLISHMENT OF FOUR LINES OF TRANSPLANTABLE RAT LEUKEMIA INDUCED BY N-NITROSOBUTYLUREA IN DONRYU RATS. (E.) Odashima, S. (Nat'l. Inst. Hyg. Sci., Tokyo, Japan) and F. C. Wang. *Gann* 61(6):597-600, 1970.

Establishment of 4 lines of myelogenous leukemia in Donryu rats induced by N-nitrosobutylurea (0.01% in drinking water till sacrifice) and application of various carcinogens (4-nitroquinoline-1-oxide, N-nitrosobutylurea, N-methyl-N'-nitro-N-nitrosoguanidine or 7,12-dimethylbenz(a)anthracene) to the mucosal surface of the glandular stomach has been studied. Smear preparations of ascites and peripheral blood of test animals following i.p. injection of 1-2 ml of blood from leukemic rats revealed leukemic cells in 1-wk-old ascites in 8 of 10 cases, but they were not detected in 3-wk-old ascites except 1 in which tumor cells grew progressively until death. One to two-wk-old tumor ascites transferred i.p. into the second generation showed 4 of 7 lines growing successfully. In one line (DBLA-10), the median survival time was 85 days compared to a 14-20 day period for the remaining 3 lines (DBLA 1, 6 and 9). In these 3 lines, leukemic cells proliferated rapidly reaching a pure culture state in 7-10 days followed by rapid degeneration of leukemic cells whereas the DBLA-10 line proliferated gradually and reached a pure culture state in several wk after inoculation. In lines 1, 6 and 9 an increase in WBC was seen 5-7 days after inoculation and continued to increase even after disappearance of leukemic cells from the ascites. In line 10 WBC did not increase in most cases and only a few leukemic cells were detectable in the circulating blood. Autopsy findings in lines 1, 6, and 9 showed proliferation of leukemic cells in spleen, periportal tissues of the liver and its sinusoids, thymus and bone marrow, interstitial tissues

of the kidney, adipose tissue of the peritoneal cavity, lung alveoli and lymph nodes, whereas in line abundant tumor nodules appeared on the peritoneal surface accompanied by enlargement of thymus and hepatosplenomegaly.

1354 LEIOMYOSARCOMAS INDUCED BY ORAL ADMINISTRATION OF N-METHYL-N'-NITRO-N-NITROSOGUANIDINE IN GASTRIC CYSTS GRAFTED IN SUBCUTANEOUS TISSUE OF MICE. (E.) Matsuyama, M. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan), H. Suzuki and T. Nakamura. *Gann* 61(6):523-527, 1970.

The carcinogenic effects of N-methyl-N'-nitro-N-nitrosoguanidine (NG) on gastric cysts developed on stomach grafts were investigated in mice. New-born mice of both sexes were engrafted with sheets of the glandular stomach of litter mates. At 2 months of age when the gastric cysts were established in the s.c. tissue, the mice were started on continuous administration of NG in their drinking water (50 mg/L). All the cysts of mice given NG contained chocolate-colored, condensed solution, while cysts of mice given water were clear and serous. Leiomyosarcomas developed in the grafts in 5 of 20 NG-treated mice, and atypical hyperplasia developed in the cyst epithelial cells in 2 cases; no tumors developed in control animals. The latency period for formation of tumors on the grafts was 311-415 days. Lung adenomas and ovarian tumors were also found in the NG-treated mice. The mechanism by which NG causes tumorigenesis in the cysts is obscure.

1355 PROMOTION BY DNA OF THE PHOTOINDUCED RADICAL PRODUCTION FROM 4-NITROQUINOLINE-1-OXIDE IN AQUEOUS MEDIUM AT 77°K AND ITS MECHANISM (E.) Okano, T. (Tohoku U. Sch. Med., Sendai, Japan), A. Takadate and K. Uekama. *Gann* 61(6):541-549, 1970.

Quantitative examinations on the electron spin resonance spectroscopic behavior of 4-nitroquinoline-1-oxide in the presence of DNA and its nucleosides were made utilizing calf-thymus DNA, deoxyguanosine, deoxyadenosine, deoxythymidine and deoxycytidine. The electron spin resonance spectra exhibited a weak signal at 77°K which was seen to become larger as the time of photoirradiation progressed; no signal was observed at room temperature irrespective of photoirradiation. The second derivative exhibited a single peak after 20 min of photoirradiation, and the presence of DNA did not promote any signal with or without photoirradiation, and the g-value (2.006) and line widths (21 gauss) of the original spectrum were unaffected. The 4 component nucleosides exhibited no signal, and the extent of the promotive effect on radical production decreased in the order of deoxyguanosine>deoxyadenosine>deoxythymidine>deoxycytidine.

1356 DNA REPAIR SYNTHESIS IN MAMMALIAN CELLS EXPOSED TO A SERIES OF ONCOGENIC AND NON-ONCOGENIC DERIVATIVES OF 4-NITROQUINOLINE-1-OXIDE (E.) Stich, H. F. (Cancer Res. Ctr., U. British Columbia, Vancouver, Canada), R. H. C. Smith and Y. Kawazoe. *Nature* 229(5284):416-419, 1971.

Unscheduled DNA synthesis was observed by autoradiographic studies of the incorporation of ^3H -thymidine into cultured Syrian hamster cells exposed to various isomeric and substituted 4-nitroquinoline-1-oxides. Among the various isomeric nitroquinoline-1-oxides, only the highly oncogenic 4-nitroquinoline-1-oxide-induced lesions resulted in extensive DNA repair synthesis, while virtually all substituted derivatives elicited DNA repair synthesis in varying dose-dependent degrees; maximal levels of label incorporation occurring in cells exposed to weakly oncogenic derivatives were lower than in tissues treated with highly oncogenic compounds. The hydroxyamino acid and pyridine derivatives elicited relatively high DNA repair synthesis. Initial treatment with ultraviolet irradiation produced no remarkable change in DNA synthesis, but an additive effect was noted when applications of two carcinogens were used at intervals of less than 10 hr. Compounds active in eliciting DNA repair synthesis exerted an inhibitory effect on the entry of cells into the S phase while cells exposed to 4-nitroquinoline-1-oxide before addition of oncogenic SA7 virus resulted in at least a 20-fold increase in transformation frequency from cells infected with the virus alone.

- 1357 CYTOCIDAL ACTION OF CARCINOGENIC 4-NITROQUINOLINE-1-OXIDE AND RELATED COMPOUNDS. (E.) Tokuzen, R. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), M. Araki, M. Saneyoshi and F. Fukuoka. *Gann* 61(6):601-603, 1970.

The cytotoxic activity of carcinogenic 4-nitroquinoline-1-oxide and related compounds was assayed by incubating Nakahara-Fukuoka sarcoma grafts with 0.05-0.005% of the test compound for 24 hr and then observing the growth of the tumor after transplantation into mice. The cytotoxic and carcinogenic activity of the parent nitroquinoline compounds and their corresponding hydroxyamino-derivatives paralleled each other completely. The relationship between the cytotoxic and carcinogenic actions of this group was further supported by the absence of cytotoxic activity in the non-carcinogenic quinoline derivatives such as 4-aminoquinoline-1-oxide, 4-hydrazinoquinoline-1-oxide, 4-acetylhydrazinoquinoline-1-oxide, 4-azidoquinoline-1-oxide, 8-hydroxyquinoline-1-oxide, and 3-nitro-4-hydroxyquinoline-1-oxide.

- 1358 METABOLISM OF CARCINOGENIC 4-HYDROXYAMINOQUINOLINE-1-OXIDE IN MICE. (E.) Kawazoe, Y. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), M. Tamura and M. Araki. *Gann* 61(6):593-596, 1970.

The metabolism of 4-hydroxyaminoquinoline-1-oxide in ddN strain female mice was studied by the reverse dilution method utilizing ^3H -labeled metabolites. The subcutaneously administered carcinogen (0.5 mg) was quickly metabolized even at the site of injection into 4-aminoquinoline-1-oxide, 4-aminoquinoline, and 4-hydroxyquinoline-1-oxide with maximum concentrations in blood appearing within 0.5 hr after the injection. At the earlier stages the main constituent extracted from all sites examined was 4-hydroxyamino-

quinoline-1-oxide; at injection site, blood and lung 4-hydroxyquinoline-1-oxide was the main component with the liver showing 4-aminoquinoline in highest concentration.

- 1359 DEVELOPMENT OF SARCOMAS IN MICE AT SITE OF INJECTION WITH A NEW CARCINOGEN, MONO-ACETYL DERIVATIVE OF 4-HYDROXYAMINOQUINOLINE. (E.) Sato, K. (Fac. Educ., Hirosaki U., Japan), T. Saito and M. Enomoto. *Jap J Exp Med* 40(6):475-478, 1970.

Female mice given 20 s.c. injections of 0.12 mg of a monoacetyl derivative of 4-hydroxyaminoquinoline (AcHAQ) developed fibrosarcomas and myosarcomas at the injection site in 17 of 20 DDD mice. A diacetyl derivative of 4-hydroxyaminoquinoline (DiAcHAQ, 0.15 mg) induced similar sarcomas in 13 of 21 mice. AcHAQ produced sarcomas in 84 days from the day of injection, while DiAcHAQ produced tumors in 102 days. AcHAQ also induced lung adenomas and s.c. sarcomas in 20 of 30 mice injected shortly after birth with 53 μM moles of the agent; 4-nitroquinoline-1-oxide (53 μM moles) induced tumors in 6 of 18 animals. The high carcinogenic activity of AcHAQ suggests that this compound might be a proximate carcinogen of 4-nitroquinoline.

- 1360 L-CYSTEINE AS PROTECTOR AGAINST ABERRATION RELEASING ACTION OF 8-HYDROXYQUINOLINE SULFATE IN HUMAN LEUKOCYTE CHROMOSOMES. (Ger.) Gebhart, E. (Inst. Humangenet., U. Erlangen-Nuremberg, Germany). *Mutat Res* 11(2):261-262, 1971.

The protective action of L-cysteine against 8-hydroxyquinoline sulfate (8-HCHS) was tested in human lymphocyte cultures from the peripheral blood of blood donors. The tests were conducted for different time intervals (24 hr, 1 hr) and with different concentrations of 8-HCHS (5.10^{-6}M , 1.10^{-5}M), for 100 metaphases. The cysteine effect reduced substantially the metaphases with chromosomal structure defects, especially the chromatid gaps and the isochromatid gaps. In addition, L-cysteine was shown to affect the last period of the S-phase (6 hr recovery), the aberrant metaphases dropping from 52% to 17% in the first case and from 37% to 24% in the second case. Treatment with L-cysteine after lymphocyte incubation with 8-HCHS revealed the protective effect of this substance to be even more marked, especially in the chromatid- and isochromatid gaps.

- 1361 TUMOR INDUCTION BY REPEATED INJECTIONS OF URETHAN IN NEWBORN AND ADULT HAMSTERS: AGE INFLUENCE. II. (E.) Toth, B. (U. Nebraska Coll. Med., Omaha). *J Nat Cancer Inst* 46(1):81-93, 1971.

The study of age influence in urethan-induced carcinogenesis in Syrian golden hamsters at birth and adult age is reported. Day-old and 8-week-old hamsters were given a single i.p. injection of urethan (1 mg/g body wt) once a wk for 9 wk. Nine of the females in which treatment was started at birth developed 16 tumors of the cecum, 8 of which were polypoid

adenomas and the remainder, adenocarcinomas. In newborn males, 13 developed 23 cecal tumors, 12 of which were classified as polypoid adenomas and 11 as adenocarcinomas. Seven females in which treatment was started at 8 wk developed 8 cecal tumors, 4 of which were classified as polypoid adenomas and the remainder as adenocarcinomas; 8 males developed 9 cecal tumors, 5 of these being polypoid adenomas, and 4 were adenocarcinomas. In males in which treatment was started at birth, 2 developed 2 adenomas of the colon at 82 and 112 wk, and 2 males had 3 adenocarcinomas at 50, 50 and 101 wk; 1 female developed an adenocarcinoma at 40 wk, and 1 female whose treatment started at adulthood developed a similar tumor at 87 wk. In animals in which treatments were started at birth, 8 females developed 8 thyroid tumors, 6 of which were adenomas of the thyroid and 2 were carcinomas; 3 males developed 2 adenomas and 1 carcinoma of the thyroid. With treatment started at 8 wk, 6 females developed 6 adenomas of the thyroid and 1 carcinoma, with a single adenoma observed in 1 male. Dermal melanocytomas occurred in 26 of 40 female and 21 of 33 male animals injected at birth, while 41 melanocytomas among 38 females and 27 among 39 males developed when injections started at 8 wk. Squamous cell carcinomas of the forestomach were seen in 2 animals of each sex in which treatments were started at birth and in 5 females and 4 males receiving first injections at 8 wk.

- 1362 *IN VIVO* INTERACTION OF URETHAN WITH NUCLEIC ACIDS AND PROTEINS. (E.) Prodi, G. (Inst. Gen. Path., U. Bologna, Italy), P. Rocchi and S. Grilli. *Cancer Res* 30(12):2887-2892, 1970.

In vivo studies on the interaction of urethan with nucleic acids and proteins of rat organs was followed with the use of labeled carbamate compounds. All fractions of the organs (liver, spleen, lung, kidney, skin) showed considerable radioactivity 24 hr after injection with ethyl carbamate- $1-^{14}\text{C}$ with protein fractions showing higher activity than that of nucleic acids; maximum binding was noted in skin, and in decreasing order, in spleen, lung, liver, and kidney. RNA activity was higher than DNA activity in all organs except that of kidney RNA which exceeded that of liver RNA. DNA activity versus time was almost constant and RNA activity increased from 15 to 48 hr, while nuclear protein activity peaked at 15 hr and cytoplasmic protein showed differences in various organs with the use of ethyl carbamate- $2-^3\text{H}$. Activity found in all organs 24 hr after i.p. injection of ethyl carbamate carboxyl- ^{14}C was 20- to 100-fold lower than that determined with ethyl carbamate- $1-^{14}\text{C}$. Acid hydrolysis of RNA removed radioactivity from AMP and GMP; characteristics of the labeled moiety was not coincidental with ribose, adenine, or guanine. DNA did not react to acid hydrolysis. Urethan interaction with nucleic acids appears not to be due to metabolic utilization of the labeled compound in the synthesis of nucleotides.

- 1363 INCIDENCE OF CANCER IN MEN ON A DIET HIGH IN POLYUNSATURATED FAT. (E.) Pearce, M. L. (Wadsworth Hosp. Med. Serv., VA Ctr., Los Angeles, Calif.) and S. Dayton. *Lancet* 1(7697):464-467, 1971.

The development of cancer in 846 men participating in a study of the effects of a high polyunsaturated fat diet on atherosclerotic events was investigated. Although atherosclerotic events were more common in the group maintained on a conventional diet, an excess of non-atherosclerotic deaths was observed in the experimental diet group. The excess was accounted for by a greater incidence of fatal carcinomas in the experimental group. In the conventional diet group, 17 deaths were due to carcinoma; in the polyunsaturated fat-rich diet group, there were 31 cancer deaths. There was a higher incidence of visceral carcinomas in the experimental group than in the control group. Cancers of the lung and bronchus were the most common malignancies in both experimental and control groups, accounting for 12 deaths in the control group and 16 deaths in the experimental group. Cigarette smoking habits were not correlated with carcinoma incidence in either group to the degree of statistical significance; no non-dietary explanation suggested itself for the frequency of cancer deaths in the experimental group.

- 1364 THE CYTOGENETIC EFFECT OF CYCLOPHOSPHAMIDE ON A BURKITT TUMOR CELL LINE (EB_4) *IN VITRO*. (E.) Bishun, N. P. (Marie Curie Mem. Found., Oxford, Surrey, England). *Mutat Res* 11(2):258-260, 1971.

Treatment of a cell culture from a Burkitt's lymphoma tumor arising in a 15-yr-old English girl with cyclophosphamide resulted in increased frequencies of chromosomal aberrations. Cells from the Burkitt tumor were arrested in metaphase by the addition of colchicine, and cyclophosphamide was added to cultures at amounts of 0.001, 0.01, 0.025 or 0.05 $\mu\text{g}/\text{ml}$. Cyclophosphamide treatment, in all 4 doses, increased occurrence of chromosomal aberrations, including polyploidy, chromatid breaks, chromatid gaps, quadriradials and rings. Chromosomal aberrations did not appear to be dose-related. In Burkitt's lymphoma cells treated with cyclophosphamide (0.001 μg), the percentage of polyploidy was 10.5, while in control cells the percentage was 1.5. Percentages of chromatid gaps and breaks in treated (0.01 μg) and untreated cells were 23 and 10, and 42 and 7, resp. Percentages of quadriradials in treated (0.025 μg) and untreated cells were 7 and 1, resp. Rings were seen only in control cells, and dicentric chromosomes were seen only in controls and in cells treated with (0.025-0.001 μg) cyclophosphamide.

- 1365 MYELOMONOCYTIC LEUKAEMIA SUPERVENING ON CHRONIC LYMPHOCYTIC LEUKAEMIA. (E.) Catovsky, D. (Roy. Postgrad. Med. Sch., London, England) and D. A. G. Galton. *Lancet* 1(7697):476-479, 1971.

A case is reported in which a 54-yr-old man developed myelomonocytic leukemia following remission of chronic lymphocytic leukemia. After approximately 6 yr of comparative good health following the disappearance of symptoms of chronic myelocytic leukemia, the patient presented with a lymphocyte count of 5000/ μ l, hypercellular bone marrow, and low serum-immunoglobulin levels. On the basis of lysozyme estimations, total vitamin B₁₂ binding capacity tests, and lymphocyte "blast" transformation studies, it was concluded that the patient had myelomonocytic leukemia. Chlorambucil, which the patient had received continuously for 40 months for treatment of chronic lymphocytic leukemia, may have been responsible for the subsequent development of myelomonocytic leukemia.

1366 EXPERIMENTAL STUDIES ON INTAKE AND DEPOSITION OF SMOKE PARTICLES IN GOLDEN HAMSTERS WHEN EXPOSED TO CIGARETTE SMOKE. (Ger.) Montenwill, W. (Res. Inst. Cigarette Industry, Hamburg, Germany), H. P. Harke, A. Baars and E. Goertz. *Arzneimittelforschung* 21(1):142-143, 1971.

The deposition of smoke particles in 10 male Syrian golden hamsters was investigated by means of n-hexadecane/n-hexadecane-1-¹⁴C. The animals were sacrificed immediately following their exposure to the smoke, and the lungs, trachea, larynx and tongue were analyzed for radioactivity. Radioactivity was determined in terms of labeled CO₂ derived from incineration of the respective organs. The results revealed that absorption in the nasal cavity was less than 50% of the smoke particles, and only about 20% of the activity was found in the head. In the respiratory tract, about 70% of the activity was found in the lungs, with 3-4% retained in the larynx, 3-6% on the tongue surfaces, and 1.5-3% in the trachea. The highest deposit of smoke particles per unit of surface was found in the area of the larynx.

1367 THE EFFECT OF CHRONIC INHALATION OF FRESH CIGARETTE SMOKE AND ITS GASEOUS PHASE UPON THE DEVELOPMENT OF PULMONARY TUMORS IN SNELL MICE. (Ger.) Leuchtenberger, C. (Swiss Inst. Exp. Cancer Res., Lausanne) and R. Leuchtenberger. *Z. Praeventivmed* 15(6):457-462, 1970

A smoking apparatus allowing for intermittent puffs of fresh air and fresh cigarette smoke was used to simulate human smoke inhalation in Snell mice. The type of pulmonary carcinoma found in man was not found in Snell mice but 2 types of glandular tumors were observed in these animals, benign adenomas and adenocarcinomas. The control male animals developed more spontaneous lung tumors (12.2%) than did the females (5.1%). Male mice exposed to whole cigarette smoke or to the gas phase only also had higher incidences of lung tumors (16.8% and 25.0%, resp.) than female mice (10.7% and 18.2%, resp.). Tumors developed after a shorter latent period in experimental animals than in controls, and animals exposed to the gas phase only had even shorter latent periods for tumor formation. These results indicate that the volatile components rather than the smoke particles are the active carcinogenic agents in tobacco smoke.

1368 ARSENIC AND EPITHELIOMAS OF THE SKIN. (Ger.) Fritsch, P. (U. Clin. Vienna, Austria), F. Schellander and K. Konrad. *Wien Klin Wschr* 83(1):7-11, 1971.

The role of arsenic as a carcinogen was studied by means of a questionnaire addressed to 619 subjects, of whom 419 had epitheliomas. The epitheliomas were comprised of deep and superficial basal cell carcinomas, Bowen's disease and Bowen carcinoma. The results of the questionnaire revealed that in the Bowen epithelioma and superficial basal cell carcinoma groups, positive histories of contact with arsenic were found in 36% of the cases compared with 14% of the controls. The type of exposure to arsenic was found to be due to medication more often than to exogenous contact, the latter being found more frequently in men than in women. More patients with epitheliomas reported contact with arsenic over a longer period of time than did the controls, and all the patients reported more numerous contacts with arsenic than did the controls. Bowen's disease and superficial basal cell carcinoma patients showed significantly more signs of chronic arsenic poisoning than did any of the other groups including controls. No definite conclusion could be drawn from these results to implicate arsenic as a carcinogen.

1369 LONG-TERM MORTALITY STUDY OF STEELWORKERS: V. RESPIRATORY CANCER IN COKE PLANT WORKERS. (E.) Lloyd, J. W. (Natl. Environ. Hlth. Sci., Natl. Inst. Hlth., Bethesda, Md.). *J. Occup Med* 13(2):53-68, 1971.

Investigation of statistics on mortality from all causes among steelworkers employed in 1953 and previously indicated that there is an excess of mortality from respiratory cancer among workers in the coke plant sector of steel plants; the observed respiratory cancer mortality among coke oven workers was 20, and the expected mortality was 7.5. Workers on the tops of the coke ovens accounted for the greatest part of this excess, observed and expected deaths from lung cancer in this group being 19 and 2.6, resp. Ninety percent of the coke oven workers studied were nonwhite; the excess risk for oven workers, and especially for topside oven workers, therefore explains the apparent excess lung cancer mortality among nonwhite steelworkers. Lung cancer mortality for whites and nonwhites employed at stations other than the top of the coke oven shows no nonwhite excess. Workers employed for 5 yr or more at topside coke oven jobs were found to be at a 10 times higher risk than others; in the long-term coke oven groups observed and expected deaths from lung cancer were 15 and 1.5, resp. An excessively high risk of digestive cancer was thought to have been observed among nonoven area workers.

1370 BENZENIC HYDROCARBONS AND SEVERE HEMOPATHIES. (Fr.) Girard, R. (Fac. Med. Lyon, France), F. Tolot and J. Bourret. *Arch Mal Profession* 31(12):625-636, 1970.

History of exposure to benzene or toluene was sought in 401 cases of serious blood dyscrasia and in 124 patients without hemopathic conditions drawn from the same population. In cases where there was a suspicion of significant exposure to benzene or toluene, the product of the factory in which the subject worked and the air in the factory were analyzed. Twenty percent of patients with medullary aplasia were found to have undergone exposure to benzene or toluene; 13.6% of patients with acute leukosis and 14.7% of patients with chronic lymphoid leukemias had toxic exposure to benzene or toluene. Four percent of patients without hemopathic conditions had histories of significant exposure to benzene or toluene. The danger of toxic exposure to benzene or toluene was thought to be greater in smaller industrial plants than in large ones, for the larger industries are more aware of the dangers of such exposure than are small enterprises such as dry cleaners, garages and builders.

- 1371 BILATERAL NON-FUNCTIONING THECOMA OF THE OVARY IN EPILEPTIC CHILDREN UNDER ANTICONVULSANT THERAPY. (E.) Schweisguth, O. (Inst. Gustave Roussy, Villejuif, France), R. Gerard-Marchant, B. Plainfosse, J. Lemerle, J. M. Watchi and P. Seringe. *Acta Paediat Scand* 60(1):6-10, 1971.

Two cases of bilateral ovarian thecoma in young children undergoing anticonvulsant therapy were observed. The patients were girls aged 5.5 and 3.5 yr. Both exhibited petit mal seizures for which they were given chemotherapy. In both cases the therapy included phenobarbital and phenacetylurea, and 1 girl was also given trimethadione, and the other was given diphenylhydantoin. Symptoms of tumor development, including bloody ascites, appeared 6 months after the start of anticonvulsant therapy in 1 case, and 4 months after the start of therapy in the other case. Neither patient showed signs of precocious sexual development. Both tumors showed gross areas of hemorrhagic infarction. A third case of bilateral ovarian thecoma associated with anticonvulsant therapy was found in the literature.

PHYSICAL CARCINOGENESIS

- 1379 PATHOLOGIC EFFECTS OF DIFFERENT DOSES OF RADIOSTRONTIUM IN MICE: CHANGES IN THE HAEMATOPOIETIC SYSTEM. (E.) Nilsson, A. (Res. Inst. Natl. Defence, Sundbyberg, Sweden). *Acta Radiol* 9(6):528-544, 1970.

Quantitative, qualitative and time-dependent effects of various doses of radiostrontium on the hemato-poietic system in four groups of CBA male mice were studied. General depletion of all hematopoietic tissues occurred in all dose groups with a high frequency of aplasia in the 1.6 μ C group. The weight of the thymus diminished increasingly and the weight of the spleen increased progressively with increasing doses; an accentuated granulocytopoiesis occurred in which a discernible shift in relative proportions of granulocytes and lymphocytes in peripheral blood was noted. Involution of the thymus was accelerated and the spleen served to compensate for diminished bone marrow function with increasing doses. A difference in interrelationship of thymus, bone marrow and spleen may be involved in the differences in leukemogenesis between strontium irradiation and fractionated external irradiation.

- 1380 THE RESPONSE OF HAEMOPOIETIC COLONY FORMING UNITS TO SINGLE AND SPLIT DOSES OF γ -RAYS OR D-T NEUTRONS. (E.) Hendry, J. H. (Christie Hosp., Manchester, England) and A. Howard. *Int J Radiat Biol* 19(1):51-64, 1971.

The response of colony-forming units (CFU) of hemopoietic stem cells in the mouse femur to a single dose of D-T neutron irradiation of ^{137}Cs γ -ray irradiation was investigated by irradiating mice with a range of γ -ray or neutron doses, removing their femora, and assaying CFU. Split-dose response was examined by giving mice 2 doses of 200 rads of γ -rays separated by 2-24 hr; the survival of femoral CFU was compared with survival of a single dose of 400 rads. Survival curves for γ -rays were $D_0=85.7 \pm 4.5$ rads, extrapolation number = 3.1 ± 0.7 , and for neutrons, $D_0=58.1 \pm 3.4$ rads, extrapolation number = 1.7 ± 0.5 . Dose-fractionation of γ -rays in split dose experiments appeared to have a sparing effect on CFU, and survival curves obtained at various times after a first dose of 200 rads of γ -rays showed that a significant shoulder had reappeared within 5 hr of the first dose. When survivors were irradiated at 5, 8, or 20 hr after an initial 200 rad dose of γ -rays, a trend toward higher D_0 values was seen indicating increased radioresistance. Split dose fractionation of neutron irradiation had no sparing effect on femoral CFU.

- 1381 ^{90}Sr -INDUCED OSTEOSARCOMAS IN RADIATION CHIMAERAS. (E.) Barnes, D. W. H. (Med. Res. Counc., Radiobiol Unit, Harwell, Berkshire, England), T. E. F. Carr, E. P. Evans and J. F. Loutit. *Int J Radiat Biol* 18(6):531-537, 1970.
- The potential role of bone-marrow in the induction of osteosarcomata was tested by injection of syngeneic CBA/CBA-T6T6 and allogeneic CBA-T6T6/A chimeras with strontium-90 (20 μ C i.p.). Of the syngeneic chimeras, 2 of 13 animals died within 6 months before

tumors might be expected; 2 died at 10 months and were too autolysed for analysis; two died at 11 and 16 months, resp. of bone tumor and 7 with evident tumors were sacrificed. On cytological examination, 4 of 7 primary tumors contained aneuploid cells originating from the host; 2 of the primary tumors yielded only euploid cells of donor origin with T6T6 which, with passage, resulted in tumor lines with aneuploid chromosomes but without T6T6; one gave no cytological results, but on passage was shown to be aneuploid of host type without T6T6. Of the allogeneic chimeras, 4 of the 10 died after 9-11 months without evident tumors; 1 died after 9 months with osteoblastic tumor of the jaw; 5 were sacrificed for cytological study of tumors and were ultimately diagnosed in the first or subsequent passages as being of host origin and were aneuploid with 2 or more T6 chromosomes. In no case were the tumors established in A strain mice, though all grew progressively in CBA and (CBA-T6T6xA) F_1 . Eleven of 14 tumors induced with strontium-90 in normal mice all showed aneuploidy upon cytological examination. Most of the bone-tumors in both chimeras and normal animals were apparently endosteal in origin, resulting in bone-formation.

- 1382 OSSIFYING FIBROMA OF THE JAWS IN MICE AFTER INCORPORATION OF Ra-224 (THORIUM X). (Ger.) Luz, A. (Inst. Radiat. Res., Neuherberg, Germany) and B. Hindringer. *Verhandl Deutsch Ges Path* 54: 450-454, 1970.

The effects of long-term incorporation of Ra-224 in 2100 NMRT mice were found to induce osteoblastic sarcomas in various sections of the skeleton in 10% of the animals observed. However, a much greater proportion revealed ossifying fibroma of the jaws, mainly in the periosteal region. These changes were found in response to doses of 25 μ C/kg, were dose dependent and reached an 80% incidence at a dose of 50 μ C/kg of Ra-224. Enzyme histochemical studies showed the osteoblastic sarcomas and the ossifying fibromas to be distinguishable from each other. Alkaline phosphatase activity in ossifying fibromas was limited to the periosteum, whereas osteoblastic sarcomas were characterized by equal alkaline phosphatase activity in all the tumor cells. Two distinct types of tumors seemed to be caused by Ra-224.

- 1383 STUDIES ON THE IRRADIATION EFFECTS ON NORMAL ORGANS: IV. THE INFLUENCES OF γ -RAY IRRADIATION ON CAPILLARIES OF SMALL INTESTINE IN MICE. (Jap.) Fujiwara, K. (Sch. Med. Tokushima U., Japan). *Nippon Acta Radiol* 30(6):550-554, 1970.

A single dose of whole body γ -ray irradiation (1000 r at 50 r/min) produced partial narrowing, dilatation and increased permeability of capillaries in the small intestine in mice by 3 hr postirradiation. By 1-3 days postirradiation, these changes had become more conspicuous. When a 1800 r dose of γ -ray irradiation was fractionated into 6 or 18 separate doses over a period of 3 wk, it appeared that changes in intestinal capillaries were less pronounced than in animals given the lower single dose.

- 1384 THE RESPONSE OF THE SKIN OF SWINE TO INCREASING ABSORBED DOSES OF THE $^{10}\text{B}(\text{n},\alpha)^7\text{Li}$ REACTION: HISTOLOGIC AND CYTOLOGIC CHANGES. (E.) Archambeau, J. O. (Nassau Cty. Med. Ctr., East Meadow, N. Y.). *Radiat Res* 45(1):137-144, 1971.

Changes in the skin of swine given 950 or 1250 rads of irradiation from the $^{10}\text{B}(\text{n},\alpha)^7\text{Li}$ reaction were investigated. Two female swine were given an i.v. injection of 35 mg of boron/kg body wt followed by irradiation of a 10 cm area of the shoulder with thermal neutrons. Erythema and epilation were observed after 950 or 1250 rads. After 950 rads, there was a progressive loss of cells and thinning of the epidermis with leakage of serum and crust formation; the epidermis regenerated in 20-27 days, and the lesion healed. Following 1250 rads a similar reaction occurred, but the lesion did not heal. The nuclear volumes of basal and prickle cells increased 100% by 14 days after irradiation with 1250 rads; with 950 rads, the nuclear volumes of basal and prickle cells increased to 400% in 21 days. The mitotic index of cells at 5, 10 and 15 days after 1250 rads was zero. With 950 rads, the percent of abnormal mitoses had increased to 6% by day 7, and then the percent of abnormal mitoses dropped to 0% on day 20 and rose to 1.8% on day 27 after irradiation. An increase in capillary diameter followed irradiation in both amounts. Whereas nuclear volume and mitotic index were at control levels in swine exposed to 950 rads by 27 days postirradiation, capillary diameters continued to increase in this group.

- 1385 THE RESPONSE OF THE SKIN OF SWINE TO INCREASING ABSORBED DOSES OF RADIATION FROM A THERMAL NEUTRON BEAM. A DEGRADED FISSION NEUTRON BEAM, AND THE $^{10}\text{B}(\text{n},\alpha)^7\text{Li}$ REACTION. (E.) Archambeau, J. O. (Nassau Cty. Med. Ctr., East Meadow, N. Y.), R. G. Fairchild and H. J. Brenneis. *Radiat Res* 45(1):145-165, 1971.

A moist reaction produced in the skin of immature female and castrated male Hampshire swine is quantified following increasing absorbed doses from a thermal neutron and a degraded fission beam. After single exposures, erythema occurred during the first week inconstantly and variably with epilation appearing early during the second week, progressing to a moist reaction first seen in the third week and reaching completion between the fourth and sixth weeks. Time of epilation was 9.0 days and was complete by 31.2 days with changes being dose independent, and regrowth of hair occurred at absorbed doses of the order of 1000 rads. A moist reaction occurred in response to the thermal neutron beam in all fields over the dose range from 906-2247 rads ranging from small to progressively larger areas, and healing occurred prior to 49 days with 1446 rads or less. With the fission neutron beam a moist reaction occurred in all fields over the dose range from 350-1450 rads, progressing to larger areas with dose increase; healing occurred prior to 49 days at doses below 800 rads. A moist reaction occurred in 20 of 21 fields over the dose range of 865-2000 rads with the $^{10}\text{B}(\text{n},\alpha)^7\text{Li}$ reaction, with varying degrees of healing noted by day 49. The reduced biologic effect of the thermal neutron

beam is explained by the presence of a large gamma concentration.

- 1386 STIMULATED UPTAKE OF α -AMINOISOBUTYRIC ACID IN RAT LIVER FOLLOWING WHOLE BODY γ -IRRADIATION. (E.) Shihabi, Z. (Gen. Hosp. Buffalo, N. Y.) and O. W. Neuhaus. *Radiat Res* 45(1):202-209, 1971.

The effect of irradiation on amino acid incorporation by the liver was studied by following the uptake of ^{14}C - α -aminoisobutyric acid (AIB) in livers taken from rats exposed to 1300 R of γ -irradiation. When liver homogenates of irradiated rats were incubated with ^{14}C -labeled AIB, 17% of the labeled AIB was taken up by 48 hr after irradiation and 37% by 96 hr. In pair-fed unirradiated controls on the other hand, labeled AIB incorporation at 48 and 96 hr post-infection was 7 and 8%, resp. The striking increase in uptake of AIB after irradiation was apparently confined to the liver, and at the expense of other organs. Kidney, muscle, spleen and testes showed decreased amounts of label following irradiation. Treatment with aminoethylisothiuronium and cysteamine to some extent decreased AIB uptake following irradiation. Irradiation also increased hepatic uptake of radioactive phosphorus and algal hydrolysate, but inulin uptake and orotic acid uptake were not affected.

- 1387 ESTERASE ACTIVITY AND PROTEIN CONTENT OF PLASMA AND ERYTHROCYTES OF TOTALLY IRRADIATED RATS. (Ger.) Valet, G. (Max Planck Inst Biochem., Munich, Germany) and G. Ruhenstroth-Baue. *Strahlentherapie* 140(6):738-744, 1970.

Groups of 10 rats received total body irradiation 500 R, were exsanguinated (at different times), and the blood prepared for analysis. Blood volume, hematocrit, plasma protein concentration and plasma esterase activity were determined. The results revealed that there was a loss of protein following radiation, which was related to a decrease in total proteins and plasma volume; the plasma protein concentration was at first unchanged and dropped only after the 4th day following irradiation. The initial values were first regained by the plasma volume, followed by the total protein, and lastly the protein concentration, which was maintained for the longest time interval. The plasma esterase specific activity increased over the initial value between the 1st and 3rd day following irradiation, although the esterase activity/total plasma declined; there was a decrease in esterase activity over the 18 day interval following radiation for all pH values. Volume protein content and protein concentration of the erythrocytes were not significantly changed within the experimental interval.

- 1388 DNA REPAIR AND RADIATION SENSITIVITY IN HUMAN (XERODERMA PIGMENTOSUM) CELLS. (E.) Cleaver, J. E. (Lab. Radiobiol., U. California, San Francisco). *Int J Radiat Biol* 18(6):557-565, 1970.

This study was designed to assess *in vitro* sensitivity of the colony-forming ability of xeroderma pigmentosum fibroblasts as compared to that of normal fibroblasts and the levels at which repair replication is detectable utilizing punch biopsies from the forearms of patients and volunteers. Repair replication was detected in both normal, heterozygote and homozygote fibroblasts with quantitative measurements obtained at the level of 220 ergs/mm²; there appeared to be 0-25% of the normal repair in xeroderma pigmentosum cells with no simple difference between the levels of repair in the two forms. The ability of xeroderma pigmentosum cells to form colonies after ultraviolet irradiation was reduced and survival curves for both cell-types appeared to be exponential; regression lines calculated with all data points gave $n=1.0$, $d_0=29$ ergs/mm² (correlation coefficient of 0.989) for normal cells, $n=0.9$, $D_0=9$ ergs/mm² (correlation coefficient of 0.995) for abnormal cells. Xeroderma pigmentosum, in which malignancy is correlated with low repair, may illustrate a special restricted mechanism of carcinogenesis.

- 1389 RADIOSENSITIVITY OF MAMMALIAN CELLS: IV. CHANGE OF DNA CONTENT IN NUCLEI OF RAT SOMATIC CELLS AFTER IRRADIATION. (E.) Kobayashi, J. (Sch. Med. Tokushima U., Japan). *Tokushima J Exp Med* 17:47-55, 1970.

The effect of irradiation on DNA content of rat embryo somatic cells (Wistar strain) after a dose of 500 R was studied, utilizing spectrophotometry to determine DNA content of individual nuclei. Liver nuclear DNA content was most markedly decreased after 10 hr irradiation, with normal distribution regained 20-25 hr after exposure. In kidney cells, the average DNA content per nucleus decreased 5-10 hr after irradiation to a low of 88-90% of control values and returning to normal within 15-20 hr. In brain cells, the average DNA content decreased after 5-15 hr and returned to normal after 20-25 hr. Distribution frequencies of cells with below control DNA content showed peak values at 10 hr for liver cells and 5 hr for kidney and brain cells. Present data suggest that the decrease of the DNA content in somatic cells was associated with physicochemical changes of Feulgen-positive DNA in nucleoproteins.

- 1390 RADIOSENSITIVITY OF MAMMALIAN CELLS: V. DNA SYNTHESIS IN MOUSE SOMATIC CELLS AND TUMOR CELLS *IN VITRO* AFTER IRRADIATION. (E.) Kobayashi, J. (Sch. Med. Tokushima U., Japan). *Tokushima J Exp Med* 17:105-107, 1970.

DNA synthesis in mouse kidney, liver and Ehrlich tumor cells of Swiss albino mice was studied *in vitro* by measuring ³H-thymidine incorporation after an X-irradiation dose of 500 R. Incubation for 30 min showed an increase in label incorporation with a subsequent decrease of 50% within 1 hr followed by an increase to control levels within 24 hr with kidney cells. In liver cells, a similar pattern was noted, but a more gradual decrease after 1 hr of irradiation occurred; in Ehrlich cells, label was

found in 49.1% of cells after 30 min, 24.6% after 1 hr and 12.8% after 5 hr. These results show that inhibition of DNA synthesis by irradiation is similar in somatic and tumor cells.

- 1391 RELATION OF X-RAY-INDUCED THYMIDINE UPTAKE TO CHROMOSOME REVERSION AT PROPHASE IN GRASSHOPPER NEUROBLASTS. (E.) Thornton, J. (U. Texas Southwestern Med. Sch., Dallas) and M. E. Gauden. *Int J Radiat Biol* 19(1):65-78, 1971.

Unscheduled DNA synthesis in the grasshopper neuroblast of embryo cultures at prophase have been studied through identification of X-ray induced thymidine uptake, using autoradiograms for re-identification. The initial-late prophase was the latest point in the cell cycle of the neuroblast at which unscheduled DNA synthesis occurred with X-irradiation of 500-1000 R. Thymidine uptake induced by 32 R of X-rays in the latter part of prophase occurred only in reverted cells under isotonic conditions indicating reversion of recondensation in the chromosome. Slightly hypotonic medium increased thymidine uptake induced by 32 R of reverted and delayed cells. Some degree of chromosome decondensation appears to be a necessary but not sufficient condition for induction of radiation-induced ³H-thymidine uptake by neuroblasts.

- 1392 THE RATE OF TRANSLOCATIONS INDUCED IN SPERMATOGONIA OF MICE BY TWO X-IRRADIATION EXPOSURES SEPARATED BY VARYING TIME INTERVALS. (E.) Leonard, A. (C.E.N.-S.C.K., Mol, Belgium) and G. Deknutt. *Radiat Res* 45(1):72-79, 1971.

The induction of translocations in the spermatogonia of mice by 2 successive exposures to X-irradiation was investigated. Male mice were given 250 r of X-irradiation followed 1-10, 16 or 24 hr later by another 250 r dose; other rats were given a single 500 r dose, or a single 250 r dose. Between 80-100% of spermatocytes undergoing translocations showed 1 translocation; 1-10% had 2 or 3 translocations. Eight percent of spermatocytes showed translocations following a single 500 r dose, and 4.25% showed translocations following a single 250 r dose. Maximum percentages of cells showing translocations were attained when the second X-ray dose followed the first by 16 hr (8.40% of spermatocytes showing translocations). The minimal proportion of cells showing translocations (4.44%) was reached when the time interval between doses was 7 hr. Percentages of cells showing translocations continued to rise and fall with the interval between X-ray doses, without showing a prolonged increase or decrease. The results may represent a differential susceptibility to radiation of cells in various cycle-stages.

- 1393 MAMMALIAN CELL GENETICS: III. CHARACTERIZATION OF X-RAY INDUCED FORWARD MUTATIONS IN CHINESE HAMSTER CELL CULTURES. (E.) Chu, E. H. Y. (Oak Ridge Natl. Lab., Tenn.). *Mutat Res* 11(1):23-34, 1971.

The mutagenic effects of X-irradiation of the gene controlling 8-azaguanine (8-AG) sensitivity was investi-

gated in cultures of Chinese hamster cells. X-Irradiation induced forward mutations from 8-AG sensitivity to resistance. Cells were given varying doses of X-irradiation followed 42 hr later by treatment with 8-AG; cell survival decreased directly with increasing dose of X-irradiation. Cell density affected frequency of forward mutations in irradiated cells; the optimal inoculum for mutation was 1.25×10^5 cells/100 mm culture plate. Lower densities did not increase the final yield of 8-AG resistant mutations. Frequency of mutations/ 10^5 surviving cells increased from 1.5 for cultures not given X-irradiation to 11.4 for cultures given 400 r, and 16.0 for cultures given 800 r; above 800 r, the frequency of mutations declined to $7.5/10^5$ cells at 1200 r. In another experiment, a non-linear increase in the frequency of forward mutations was observed to accompany increasing dose of X-irradiation, the rate of induced mutations ranging from 4.2×10^{-7} to 1.8×10^{-6} mutations for 200 r and 1200 r, resp. Seventy-two 8-AG resistant mutants were tested for their ability to revert to 8-AG sensitivity; the test cells were treated with N-methyl-N'-nitro-N-nitrosoguanidine and other agents. Mutants reverted to 8-AG sensitivity after treatment with different chemical mutagens, suggesting that both point mutations and chromosome deletions may have occurred in hamster cells after exposure to ionizing radiation.

- 1394 METAPHASE CHROMOSOME ABBERATIONS IN CHINESE HAMSTER LIVER CELLS *IN VIVO* AFTER SINGLE ACUTE ^{60}Co EXPOSURE. (E.) Brooks, A. L. (Lovelace Found. Med. Educ. Res., Albuquerque, New Mexico), R. F. Peters and M. D. Rollag. *Radiat Res* 45(1):191-201, 1971.

The induction of metaphase chromosomal aberrations by ^{60}Co irradiation was investigated *in vivo* in Chinese hamster liver cells. Hamsters were exposed to 150 R whole body ^{60}Co irradiation 1 hr before, or 24 and 48 hr after, partial hepatectomy; in other experiments, animals were given differing doses of radiation. The total number of chromosome breaks/cell scored at the 3 exposures was similar, ranging from 0.09-0.13 breaks/cell; this appeared to suggest that liver cell chromosomes have about the same sensitivity to the induction of abberations at all stages of the cell cycle. The type of abnormalities observed did change relative to the time of exposure to ^{60}Co irradiation. At 1 hr before and 24 hr after hepatectomy, chromosome-type abnormalities were found, while at 48 hr after hepatectomy, chromatid-type abnormalities predominated. By 22 hr after hepatectomy, DNA synthesis, measured by uptake of ^{14}C -thymidine in liver cells was observed; ^{14}C -thymidine incorporation peaked at 28 hr after hepatectomy and remained near maximal levels through 52 hr after hepatectomy. Animals partially hepatectomized 1 hr or 7 days after exposure to irradiation showed no significant differences in the total number of aberrations/cell. Dose-response curves for metaphase abberations indicated that liver cells were more resistant to radiation-induced abberations than testis or bone marrow tissue. The frequency of abberations increased as a function of time after partial hepatectomy; by 40 hr after hepatectomy,

hamster liver cells exposed to 250 R showed .09 abberations/cell and by 54 hr after hepatectomy, the number of abberations/cell was .17. The increase represented an increase in deletions; the frequency of rings and dicentrics remained unchanged.

- 1395 RECTAL REACTION FOLLOWING RADIATION THERAPY OF CERVICAL CARCINOMA: PARTICULAR REFERENCE TO SUBSEQUENT OCCURRENCE OF RECTAL CARCINOMA. (E.) MacMahon, C. E. (U. Washington Med. Sch., Seattle) and J. M. Rowe. *Ann Surg* 173(2):264-269, 1971.

Six cases of carcinoma developing in the rectum and recto-sigmoid following radiation treatment of cervical cancer were reported. The patients ranged in age from 25-65 yr, and the time elapsed from irradiation to onset of rectal tumors was 14 months to 25 yr. Tumors were adenocarcinomas of the rectum and/or recto-sigmoid in 5 cases, and papillary adenocarcinoma of the rectum in 1 case. Tumors invaded the muscle in 2 cases and the muscle and serosa in 3 cases.

- 1396 NEOPLASMS AFTER CHILDHOOD IRRADIATION OF THYMUS GLAND. (E.) Janower, M. L. (Massachusetts Gen. Hosp., Boston) and O. S. Miettinen. *JAMA* 215(5):753-755, 1971.

The association of childhood diagnostic irradiation of the thymus and subsequent development of neoplasms was investigated in 511 irradiated children, 532 unirradiated children, the siblings of the irradiated children and the siblings of the unirradiated controls. The age at admission to the study was 4.7 yr for the irradiated children; and the mean age at the termination of the study was 34.8 yr. Fifty-seven percent were male and most were from low socioeconomic backgrounds. Patients were given total doses of 400 roentgens of irradiation. In the irradiated patients, there were 2 malignant and 9 benign thyroid neoplasms; no malignant thyroid neoplasms were observed in any of the irradiated groups, and the numbers of benign thyroid tumors in these groups totalled 10. The malignant thyroid tumors in the irradiated children were follicular carcinomas and a papillary cystadenocarcinoma; the tumors were principally adenomas. In the irradiated group, malignant neoplasms of organs other than the thyroid included 1 case of malignant lip tumor, 1 case of malignant brain tumor, 1 case of malignant cervical tumor, 1 case of disseminated lymphosarcoma, 1 case of acute myelocytic leukemia, and 3 cases of mammary carcinoma. Siblings of irradiated and unirradiated children showed no appreciable differences in tumor development.

- 1397 REPORT ON PATHO-ANATOMICAL AND RADIOAUTOGRAPHIC STUDIES OF NINE CASES OF HUMAN THOROTRASTOSIS. (Ger.) Wegener, K. (Path. Inst. U. Heidelberg, Germany) and R. Zahnert. *Virchow Arch Path Anat* 351(4):316-332, 1970.

Investigations dealing with thorotrast injections are described, including morphological and autoradiographic studies.

graphic studies and the quantitative determination of the thorotrast and its metabolic products. The thorotrastosis cases were divided into 3 different groups: Group I - organs and tissues with thorotrast storage and with delayed injury including the liver, spleen, lymph nodes, bone marrow and paravascular tissues in the area of the injection site; Group II - organs and tissues with thorotrast storage but without delayed injury including the kidneys, adrenals, tonsils, gastrointestinal tract, hepatic duct, fatty tissue, gallbladder, urinary bladder, lungs, pancreas, pleura, prostate, thyroid, vertebral discs, and testes; and Group III - organs and tissues without thorotrast uptake or late injuries including arteries and veins, bronchi and trachea, central nervous system sections and spinal column, the heart, skin, various musculature, peritoneum, and nails. The administration of thorotrast was undoubtedly responsible for liver cirrhosis in 9 cases and liver malignancies in 7 cases.

1398 LEUKEMIA IN ATOMIC BOMB SURVIVORS, HIROSHIMA AND NAGASAKI, 1 OCTOBER 1950-30 SEPTEMBER 1966. (E.) Ishimaru, T. (Nat'l. Inst. Hlth., Hiroshima, Japan), T. Hoshino, M. Ichimaru, H. Okada, T. Tomiyasu, T. Tsuchimoto and T. Yamamoto. *Radiat Res* 45(1):216-233, 1971.

The incidence of leukemia developing among survivors of the atomic bomb attacks on Hiroshima and Nagasaki, Japan, was investigated in fixed cohorts of survivors. The risk of developing leukemia was substantially greater among those exposed to significant doses of radiation. In Hiroshima, annual leukemia incidence rates/100,000 population for those exposed to 200, 300, and 400 rads of bomb radiation were 58, 80, and 120 cases, resp. In Nagasaki, the incidence of leukemia in those exposed to 200, 300, and 400 rads was 38, 68 and 78, resp. The differences in incidence in the 2 cities may reflect differences in the kind of radiation emitted by the bombs, or errors in dosimetry, or other differences between the 2 cities. The relative risk of developing leukemia in both Hiroshima and Nagasaki was greater for males than for females, especially in the high dose region. The risk of leukemia was found to be lower in persons over 40 yr of age at the time of the bombings than in younger persons. The risk of leukemia among bomb survivors declined with time after the bombings, especially among those exposed to 100 rads or less. It was found that in Hiroshima persons exposed to 5-99 rads had increased risks for acute lymphocytic leukemia and chronic granulocytic leukemia, but not for acute granulocytic leukemia.

1399 OCCUPATIONAL FACTORS IN THE EPIDEMIOLOGY OF LEUKEMIA IN HIROSHIMA AND NAGASAKI. (E.) Ishimaru, T. (Japanese Nat'l. Inst. Hlth., Hiroshima), H. Okada, T. Tomiyasu, T. Tsuchimoto, T. Hoshino and M. Ichimaru. *Amer J Epidemiol* 93(3):157-165, 1971.

The incidence of leukemia among citizens of Hiroshima and Nagasaki, Japan in various occupational groups was investigated; subjects included persons exposed to

atomic bomb irradiation in 1945 and persons not so exposed. Occupational exposure to X-irradiation and/or benzene as a solvent were found to be associated with a risk of developing leukemia on the order of 2.5 times higher than the risk of unexposed subjects. Especially high risks were found for welders, sheet metal workers, cabinet makers, rubber products workers, glass workers, barbers and radiologists. The effect of atomic bomb irradiation exposure and history of occupational exposure to benzene or medical X-rays was also investigated. The heavily bomb radiation-exposed group (exposed to 100 rads or more) which had occupational exposure to benzene or X-rays had a relative risk of developing leukemia of 1.5; the low bomb-irradiation dose group had a risk of 4.0; the unirradiated group had a risk of 2.4. In all groups exposed to atomic-bomb irradiation, risks of developing leukemia were higher in persons with histories of occupational exposure to benzene or X-irradiation.

1400 THE THORIUM-SERIES IN CIGARETTES AND IN LUNGS OF SMOKERS. (E.) Joyet, G. (Lab. Dosimetry Protection, U. Zurich, Switzerland). *Experientia* 27(1):85-89, 1971.

The accumulation of radioactive thorium (^{232}Th) in the lungs of cigarette smokers was investigated. The thorium-equivalent wt for smoke produced by 9000 cigarettes (the annual consumption of a heavy smoker) was calculated for 8 brands of British, American, and French cigarettes, and found to range from 9-36 mg. The thorium-equivalent wt in the lungs of 10 cigarette smokers and 2 nonsmokers were also calculated. Four smokers had no measurable thorium in their lungs, and 6 had thorium wt of 0.8-2.4 mg. The 2 nonsmokers had no detectable thorium in their lungs. Although the toxic effects of thorium in the lungs of smokers was not investigated, it was reported that 2 workers having occupational exposure to thorium vapor developed incapacitating dyspnea with fibrosis.

VIRAL CARCINOGENESIS

- 1411 PULMONARY ADENOMATOSIS OF SHEEP (JAAGSIEKTE): I. ULTRASTRUCTURE OF THE TUMOR. (E.) Perk, K. (Hebrew U., Rehovot, Israel), I. Hod and T. A. Nobel. *J Nat Cancer Inst* 46(3):525-537, 1971.

Pulmonary adenomas from Asassi sheep with pulmonary adenomatosis (jaagsiekte) were examined by electron microscopy and found to be composed of cells apparently derived from type B alveolar epithelial cells. Cells of advanced tumors had abundant collagen; some cells were so impregnated by collagen fibers as to cause lysis. Many of the tumor cells, as well as normal ovine B type alveolar cells, were characterized by dense osmiophilic "cytosomes" consisting of concentric or parallel lamellae. Cytosomes were more numerous and larger in adenomas than in normal cells. Glycogen granules, absent in normal alveolar cells, were common in tumor cells. free ribosomes in the form of polysomal aggregates were found in tumor cells, but not in normal cells. Golgi complexes were more extensively developed in tumor cells than in most normal cells, and only in tumor cells were there large cytoplasmic clefts and many filaments in the cytoplasmic matrix. Virus particles, though rare, were seen occasionally in the cisternae of the granular endoplasmic reticulum; cisternal viral buds were also seen.

- 1412 IN VITRO STUDIES OF RAT VIRUSES: I. EFFECTS OF LONG-TERM CULTURE. (E.) Lum, G. S. (VA Hosp., Cincinnati, Ohio). *Oncology* 24(6):401-415, 1970.

Rat embryo cells cultured for up to 5 yr (78 cell passages) showed no marked morphological differences from primary passage cells; the long-term passage cells produced only 1 tumor in 52 inoculations when inoculated into rats, that tumor being produced by cells from a 16 month-old culture. When the susceptibility to viral infection of long-term culture cells was tested, it was found that cells remained susceptible to infection by rat viruses (strains RV and L-S) through passage 33; however, resistance to infection increased in long-term cell cultures, and no cytopathic effect was seen in long-term cultures. Cells surviving persistent virus infection were maintained in long-term cultures. Some of these cultures produced virus for as long as 2 yr before becoming virus-negative, while others produced virus in cycles of varying durations; 1 culture produced virus from day 20-50, from day 70-90, from day 400-420, and from day 700-740. Some long-term cultures were resistant to re-inoculation, while others were susceptible to re-inoculation. Neutralization tests on virus released from inoculated cells after various periods of time under cultivation showed the virus to be identical to the virus used for the initial infection.

- 1413 VIRAL AND MORPHOLOGIC STUDIES ON HEPATOMAS IN MICE OF STRAIN C3H-A^{VV}, WITH OBSERVATIONS OF A CULTURED HEPATOMA. (E.) Maca, R. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), U. Heine and B. A. Manaker. *Arch Geschwulstforsch* 36(3):213-230, 1970.

Studies are reported on the etiology and morphological characteristics of spontaneously occurring hepatomas in C3H-A mice using complement-fixation histologic and electron microscopic techniques. The fine structure of tumor cells growing *in vivo* was found to be similar to that of normal hepatic cells of control animals. *In vitro* cultivation in one instance gave rise to clones of epithelioid cells surrounded by fibroblasts lacking many of the characteristic cellular features of hepatocytes. Subcutaneously transplanted tumor tissues showed regression in steroid-treated mice. A few virus particles of the "immature C-type" were found in extracellular spaces of primary or transplanted tumors, but virus particles were not seen in any hepatic tissue from 3 adult male mice free of hepatomas. Evidence of budding of particles at the cell membrane of hepatic cells was absent despite extensive examination. It is not known whether epithelioid cells or fibroblasts are the site of origin of the virus particles.

- 1414 VIRUS IN HUMAN CANCER AND LEUKEMIA. (E.) Awano, I. (Fukushima Med. Coll., Japan), M. Sanbe and H. Yoshida. *Tohoku J Exp Med* 102(3):233-263, 1970.

Biopsy materials from human cancer and leukemic tissue were examined by electron microscopy for the presence of virus particles. Virus-like particles were observed in the cytoplasm of metastatic lymph node carcinomas from patients with gastric and lung cancer. These were 100-150 mμ in size and had cores of 60-80 mμ. Mature C-type virus-like particles were found in the cytoplasm of leukemic cells of metastatic spleen and lymph node cancer cells from a patient with acute myelogenous leukemia. The cancer cells from stomach and lung cancer patients contained inclusions in the form of nuclear bodies and dense osmiophilic nuclear particles in the nucleus. Nuclear bodies were composed of small-granular cortical bands and pale homogeneous cores. The nuclear particles appeared to increase in size and develop into nuclear globules found in the nuclear body. The core of the virus-like particles in the cytoplasm may have derived from the nuclear particles. Doughnut-shaped particles were seen in the extracellular spaces between cancer cells in addition to the virus-like particles.

- 1415 TRANSFORMATION OF MOUSE EMBRYO CELLS BY VACCINA VIRUS. (E.) Kosiorowska, J. (Serum Vaccines Res. Lab., Warsaw, Poland), K. Wlodarski and N. Mazurowa. *J Nat Cancer Inst* 46(2):225-241, 1971.

Mouse embryo cells infected at low multiplicity (0.0001 plaque-forming U/cell) with vaccina virus developed low-grade infections in 90% of the cultures and 40% showed morphologic transformation. At the 12th passage level, about 90% of the transformed cells were chromosomally hypotetraploid, and 7% were hypodiploid and diploid. Morphologic examination and autoradiography revealed vaccina virus

present in the transformed cells. Tests for viral antigens with rabbit antiserum showed that vaccinia viral antigens were present in cells. Content of vaccinia antigens decreased in cells in later passages. Transformed mouse embryo cells were more resistant to superinfection than were untransformed cells. Tumorigenicity of cells in later passages was increased; tumors developed by mice injected with infected cells from early passage levels (2 wk) regressed, while tumors developed by mice injected with 62-65th passage level cells often proved fatal.

1416 FIBROSARCOMA AT THE SITE AND IMMEDIATELY FOLLOWING SMALL-POX VACCINATION. (E.)

Archampong, E. Q. (Ghana Med. Sch., Accra) and G. Clark. *Brit J Surg* 57(12):937-938, 1970.

A case of fibrosarcoma developing at the site of a smallpox vaccination was reported. The patient, a 44-yr-old woman from the Krobo State of Ghana, had received 3 smallpox vaccinations prior to the vaccination reported, which was administered by means of an injection gun apparatus. Three months after vaccination, a nodule developed at the vaccination site and was treated with cyclophosphamide. The tumor was excised twice, and it recurred both times. It was found to be a spindle-cell fibrosarcoma invading the subcutaneous tissue. While a direct association between the vaccinia and the development of the tumor was not demonstrable, the coincidence of the vaccination and the site and time of the tumor's development suggests a causal relationship between the two.
